Food and Feeding. Feeds on arthropods. Forages alone, often at edge of understorey mixed-species flocks of various antwrens and antshrikes (Thamnophilidae) and ovenbirds (Furnariidae). Posture erect and quiet on perch. Will lethargically turn its head to peer into middle storey or understorey, rapidly dart out moderate distances in upward sally or hover-glean manoeuvres to capture arthropods from undersides of leaves and twigs, then travel to new perch; sallies to air rare.
Breeding. Feb-Jun in N Colombia. Nest a bulky, pear-shaped structure 15 cm long, with downward-projecting entrance spout at side of bottom; frequently built near wasp nest in Santa Marta region of Colombia. Clutch 2-3 eggs; no information on incubation and fledging periods.
Movements. Probably resident throughout range.
Status and Conservation. Not globally threatened. Uncommon to fairly common in most of range; rare to locally uncommon in Ecuador, where apparently absent from some areas of presumably suitable lowland forest. Occurs in many national parks and other protected areas throughout its range, e.g. Darién National Park, in Panama, Tinigua National Park and Río Claro Reserve, in Colombia, Yacambú National Park, in Venezuela, Tambopata-Candamo Reserved Zone, in Peru, Madidi National Park and Pilón Lajas Biosphere Reserve, in Bolivia, and Tapajós National Park, Murici Ecological Reserve and Sooretama Biological Reserve, in Brazil. Tolerates converted habitats, and not likely to be at any risk in immediate future.
Bibliography. Anon. (1998a), Aveledo & Pérez (1994), Blake (1962), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Gilliard (1941), Haffer (1974, 1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Karr *et al.* (1990), Oren & Parker (1997), Payne (1984), Piratelli *et al.* (2002), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Todd & Carriker (1922), Tostain *et al.* (1992), Wetmore (1972), Willis (1980), Zimmer (1930, 1939c).

188. **Pacific Flatbill**

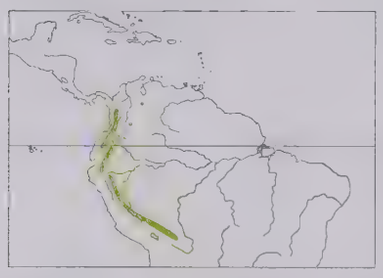
Rhynchocyclus pacificus

French: Platyrhynque de Colombie **Spanish**: Picoplano del Pacífico
German: Pazifik-Breitschnabeltyrann

Taxonomy. *Craspedoprion pacificus* Chapman, 1914, Juntas de Tamaná, Chocó, Colombia.
Was for long considered a race of *R. brevirostris*; the two may not be sister-taxa. Monotypic.
Distribution. Chocó region of W Colombia (S from mid-Atrato Valley) and NW Ecuador (Esmeraldas S to S Pichincha).

Descriptive notes. 15 cm; 23·5-26·5 g. Large-headed flycatcher. Has dark olive head and upperparts, indistinct grey eyering; wings and tail dusky brown, conspicuous tawny-buff or ochre margins of wing-coverts (no wingbars), olive margins of primaries and secondaries, buff margins on tertials; throat and breast flammulated olive with faint yellow shaft streaks, belly and flanks yellow, flanks streaked olive; iris dark; bill large, broad and flat, upper mandible black, lower mandible pale; legs blue-grey. Sexes alike. Juvenile undescribed. Voice. Song a fast series of descending clear to burry notes, "tchwee-tee-te-tu-tu-tu"; call a hissing "scheeeuw".

On following pages: 189. Fulvous-breasted Flatbill (*Rhynchocyclus fulvipectus*); 190. Yellow-olive Flycatcher (*Tolmomyias sulphurescens*); 191. Orange-eyed Flycatcher (*Tolmomyias traylori*); 192. Yellow-margined Flycatcher (*Tolmomyias assimilis*); 193. Grey-crowned Flycatcher (*Tolmomyias poliocephalus*); 194. Yellow-breasted Flycatcher (*Tolmomyias flaviventris*); 195. Cinnamon-crested Spadebill (*Platyrinchus saturatus*); 196. Stub-tailed Spadebill (*Platyrinchus cancrominus*); 197. White-throated Spadebill (*Platyrinchus mystaceus*); 198. Golden-crowned Spadebill (*Platyrinchus coronatus*); 199. Yellow-throated Spadebill (*Platyrinchus flavigularis*); 200. White-crested Spadebill (*Platyrinchus platyrhynchos*); 201. Russet-winged Spadebill (*Platyrinchus leucoryphus*).



Habitat. Lower growth of humid lowland forest and mature secondary woodland, usually sea-level to 1000 m; to 800 m in Ecuador, to 1100 m in Colombia (Valle). Replaced by *R. fulvipectus* at higher elevations.
Food and Feeding. Feeds on arthropods. Forages alone or in pairs, often at edge of understorey mixed-species flocks including furnariids, *Myrmotherula* antwrens and antshrikes (Thamnophilidae). Sits erect and quiet on low perch, such as open branch or liana, turning head to peer upwards into mid-storey or understorey; Rapidly darts out medium distances in upward sally or hover-glean manoeuvres to capture prey from undersides of leaves and twigs, then drops to new perch; rarely sallies to air.
Breeding. Birds in breeding condition from Mar in Colombia. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common; often overlooked. Restricted to Chocó region. Uncommon in Río Palenque Science Centre and Tinalandia Private Reserve, in Ecuador; small numbers recorded from forest patches in Pichincha.
Bibliography. Chapman (1917c), Cory & Hellmayr (1927), Cracraft (1985), Haffer (1975), Hilty (1997), Hilty & Brown (1986), Jahn & Mena (2002g), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Strewe (2000b), Zimmer (1939c).

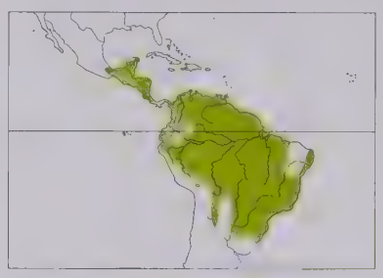
189. **Fulvous-breasted Flatbill**

Rhynchocyclus fulvipectus

French: Platyrhynque à poitrine fauve **Spanish**: Picoplano Pechirrufo
German: Ockerbrust-Breitschnabeltyrann

Taxonomy. *Cyclorhynchus fulvipectus* P. L. Sclater, 1860, Nanegal, Pichincha, Ecuador.
Monotypic.
Distribution. Andes of W Venezuela (Táchira), Colombia (W range, also W slope of E range in Cundinamarca), NW & E Ecuador, E Peru and NW Bolivia.

Descriptive notes. 15 cm; 26 g. Large-headed flycatcher. Has dark olive head and upperparts, faint pale greyish eyering; wings and tail duskier, conspicuous tawny-buff or ochre edges of wing-coverts and remiges (no wingbars); chin grey, lower throat and breast distinctively dull tawny-rufous; belly, flanks and vent yellow, streaked olive on flanks; iris dark; bill large, broad and flat, upper mandible black, lower mandible pale; legs grey. Sexes similar. Juvenile undescribed. Voice. Call (Ecuador) an infrequent wheezy upslurred "zhreeyp".
Habitat. Lower growth of humid to wet montane forest, foothill forest, second growth, and shrubby borders, especially near streams. Mainly 750-2100 m; higher, 1900-2300 m, on W slope of E Andes (S to head of Magdalena Valley) in Colombia.
Food and Feeding. Feeds on arthropods. Forages alone, often at edge of understorey mixed-species flocks. Sits erect and quiet on low perch 1-4 m up, turning head to peer upwards into mid-storey or understorey. Rapidly darts out moderate distances in upward sally or hover-glean manoeuvres to capture prey from undersides of leaves and twigs, then dropping away to new perch; rarely sallies to air.
Breeding. May in Colombia (N end of W Andes). Nest a bulky, pear-shaped structure with downward-projecting entrance spout at side of bottom, made of rootlets, coarse fibres and dead leaves, suspended from tip of thin twig or vine drooping over open space or small forest stream. Clutch presumably 2-3 eggs; no other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to uncommon; generally rare at edge of its range in Venezuela; uncommon in Ecuador. Occurs in Tambito Nature Reserve, in Colombia, and Podocarpus National Park, in Ecuador.
Bibliography. Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Hennessey, Herzog & Sagot (2003), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Strewe (2000b), Zimmer (1930, 1939c).



Genus *TOLMOMYIAS* Hellmayr, 1927

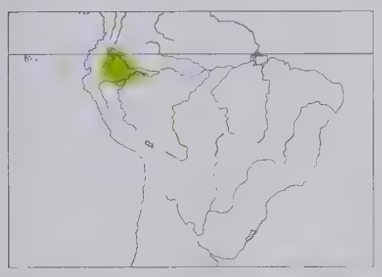
190. **Yellow-olive Flycatcher**

Tolmomyias sulphurescens

French: Platyrhynque jaune-olive **Spanish**: Picoplano Sulfuroso
German: Olivscheitel-Breitschnabeltyrann
Other common names: Yellow-olive Flatbill

Taxonomy. *Platyrhynchus sulphurescens* Spix, 1825, Rio de Janeiro, Brazil.
Relationships within genus uncertain, pending completion of major genetic study. Taxonomy of present species requires further resolution; regional differences in voice, plumage and eye colour suggest to some authorities that races may represent more than one species; some plumage variation appears clinal, but clines are discordant; several races, particularly within South America, may not be valid. Sixteen subspecies tentatively recognized.
Subspecies and Distribution.
T. s. cinereiceps (P. L. Sclater, 1859) - S Mexico (Oaxaca and Veracruz E to Yucatán Peninsula) S to Costa Rica.
T. s. flavoolivaceus (Lawrence, 1863) - E Panama and NW Colombia.
T. s. asemus (Bangs, 1910) - W & C Colombia.
T. s. exortivus (Bangs, 1908) - NE Colombia and N Venezuela.
T. s. berlepschi (Hartert & Goodson, 1917) - Trinidad.
T. s. cherriei (Hartert & Goodson, 1917) - E Venezuela, the Guianas and N Brazil (upper R Branco and Amapá).
T. s. duidae J. T. Zimmer, 1939 - S Venezuela and NW Brazil (N Amazonas perhaps to W Pará).
T. s. confusus J. T. Zimmer, 1939 - SW Venezuela, E Colombia and NE Ecuador.
T. s. aequatorialis (Berlepsch & Taczanowski, 1884) - W Ecuador and NW Peru (Tumbes, Piura).
T. s. peruvianus (Taczanowski, 1875) - SE Ecuador and N & C Peru (Amazonas, S San Martín, E Pasco, Junín).
T. s. insignis J. T. Zimmer, 1939 - NE Peru (lower R Ucayali, in Loreto) and NW Brazil (R Juruá E to R Jamundá and R Madeira).
T. s. mixtus J. T. Zimmer, 1939 - NC Brazil (E Pará, NW Maranhão).
T. s. inornatus J. T. Zimmer, 1939 - SE Peru (N Puno).
T. s. pallescens (Hartert & Goodson, 1917) - C, S & E Brazil (S Maranhão, Piauí and Paraíba S to Mato Grosso, Bahia and possibly W Minas Gerais) S to Bolivia (Beni S to Tarija) and N Argentina (S to Tucumán).
T. s. grisescens (Chubb, 1910) - C Paraguay and N Argentina (E Chaco and Formosa, N Santa Fe).
T. s. sulphurescens (Spix, 1825) - E Paraguay, NE Argentina (Misiones) and SE Brazil (E Minas Gerais and Espírito Santo S to Rio Grande do Sul).

Descriptive notes. 13-15·5 cm; 14·5-15·2 g. Nominate race has dark olive crown, narrow whitish supraloral and eyering, pale olive auriculars with dusky patch towards rear; nape dark olive, upperparts olive-green; wings dusky or blackish, two yellowish-olive wingbars, yellowish margins of remiges; pale greenish-grey throat, becoming greenish-olive on breast and flanks, bright yellow on belly and undertail-coverts; iris variable, typically pale brown to pale grey; bill wide and flat, upper mandible black, lower mandible pale grey to pale flesh-coloured; legs grey. Sexes similar. Juvenile is paler below, white eyering broken, dark brown or olive iris becoming paler with maturity. Races vary in extent of olive or grey on crown and throat, general brightness of green on back and yellow on belly, also iris colour, although differences often quite subtle: *cinereiceps* has light grey crown, no dusky auricular mark, cheeks and throat pale grey, belly pale yellow, iris whitish to pale yellow; *flavoolivaceus* is rather small, has crown and throat more green, slight auricular mark, bright yellow belly; *asemus* has grey crown, dull grey throat and breast, paler dull yellow belly; *exortivus* has olive crown with slight grey tinge, grey chin, dull olive breast, medium-yellow belly; *berlepschi* and *cherriei* resemble previous, but slightly duller yellow below; *duidae* is similar to last, but darker olive breast and crown; S races *pallescens* and *grisescens* have darker olive crown than N races, lores and cheeks pale, brighter green on back, pale green-grey throat, greener breast, bright yellow belly, greyish iris, closely resemble nominate; *mixtus* appears to be somewhat transitional, has medium-yellow belly (as N group) and darker crown (as S group); *peruvianus* has rather dark grey crown, more distinct auricular patch, pale green-grey throat, dull olive breast, bright yellow belly, usually dark iris; *insignis* has olive-grey crown, duller underparts than previous, usually pale iris; *inornatus* is very like last but less olive on crown, slightly duller below; *aequatorialis* has dark grey crown, dull yellow-green breast, dark iris; *confusus* appears transitional between W & N races, with medium-grey crown, dull olive breast, medium-yellow belly. Voice. Song highly variable geographically, e.g. a series of 2-6 sharp or buzzy high notes, "dzeeyp, dzyeep, dzeep", sometimes with pause after first note, becoming sharper with each repetition, like that of *T. assimilis* but less nasal; in Venezuela, similar buzzy nasal "ps ps psst psst PSST" given N of Orinoco, whereas, S of river, typically a sharp "spik spik" with pause of 1-3 seconds between notes, or several "spik" notes in long irregular sequence; song W of Andes in Ecuador (*aequatorialis*) a thin and well-enunciated series of quick notes as 'psee-pset-pset-pset', E of Andes the notes a little longer, e.g. 'swit-swit-swit-swit-swit'; in all areas often a long pause between songs. In Panama, call thin, usually consists of 1-2 sibilant notes, "dzz", "dzz" or "tsit, tsit", sometimes followed by fast musical rattle. Voice of nominate race described as a squeaky whistle, "sheet, shi-eet", given three times.
Habitat. Wide variety of dry to humid forest habitats, including borders of humid and montane forests, and dry, deciduous and gallery forests, isolated woodlots, shady plantations, and tall secondary growth; inhabits river islands and riparian habitats in Amazonia and S Venezuela. In Surinam, common in wooded sand ridges in coastal region, savanna forest and interior. Generally does not occur in humid lowland forest (*terra firme*), where replaced by *T. assimilis* and *T. poliocephalus* (Costa Rica); where these congeners absent (SE Brazil, and E slope of Andes in Ecuador and Peru), present species does inhabit tall humid forest. Mostly lowlands below 1500 m, smaller numbers on Andean slopes to c. 1800 m (900-1700 m in W Ecuador) and to 1900 m N of Orinoco (Venezuela); to 1200 m in Mexico.
Food and Feeding. Food insects, including beetles (Coleoptera), ants (Hymenoptera), homopteran bugs; recorded prey include beetles of family Scolytidae. Small berries also occasionally taken. Forages singly or in pairs, alone or with mixed-species flocks, inside crowns and at lower and middle levels of forest. Perches with more upright posture than congeners, rarely cocks tail. Slowly and deliberately searches foliage for prey, then makes short (up to c. 2 m) sallies, upward strikes, hover-gleans, perch-gleans and aerial chases to capture prey, often from undersides of leaves, then dropping down or continuing to new perch. In Costa Rica, sometimes picks at bare branches.
Breeding. Apr-Jun in Costa Rica, Apr-Jul in Trinidad and Jan-Jun in N Colombia. Male courtship displays involve trembling with wings stretched. Nest a pear-shaped bag made of black rootlets and fungal rhizomorphs, sometimes mixed with grass and cobwebs, composed of roof, chamber (in form of a bag), and downward-pointing perpendicular "chimney" as entrance, 1·5-11 m up and often hung from exposed branch or vine, often on woodland edge, over stream or roadside, regularly near wasp nest; frequently nests in bull's horn acacia (*Acacia*) in Costa Rica; nest also used as a dormitory. Clutch 2-3 eggs; in Costa Rica, incubation by female, period 17-18 days, chicks brooded only by female, fed by both parents, nestling period 22-24 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to abundant in most of range, though somewhat local on parts of E slope of Andes. The most widespread member of genus. Occurs in numerous national parks and other protected areas. Given its tolerance of wide variety of wooded habitats, including converted habitat, and its large range, this species is considered unlikely to become threatened in near future.
Bibliography. Anon. (1998a), Binford (1989), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Di Giacomo (2004), ffrench (1991), Fjeldså & Maijer (1996), Greenberg (1992), Gyldenstolpe (1945a, 1945b), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Lee Jones (2004), Lowen *et al.* (1996), Meyer de Schauensee & Phelps (1978), Miserendino (1998), Monroe (1968), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely (1981), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), do Rosário (1996), Rowley (1984), Schulenberg &



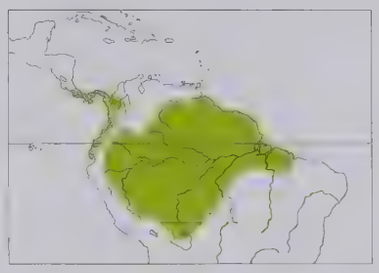
Parker (1997), Short (1975), Sick (1979b, 1993, 1997), Slud (1964), Souza (2002), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Temple (2002), Tostain *et al.* (1992), Wetmore (1926, 1939, 1972), Williams & Tobias (1994), Zimmer (1939c).

191. Orange-eyed Flycatcher

Tolmomyias traylori

French: Platyrhynque de Traylor **Spanish**: Picoplano Ojinaranja
German: Orangeaugen-Breitschnabeltyrann

Taxonomy. *Tolmomyias traylori* Schulenberg and Parker, 1997, 5 km ESE of Orán, Loreto, Peru.
Relationships within genus uncertain, pending completion of major genetic study; appears to be closely related to *T. sulphurescens* complex of taxa. Monotypic.
Distribution. SE Colombia (SE Putumayo, NW Amazonas), E Ecuador (E Napo) and NE Peru (N of Amazon in Loreto).



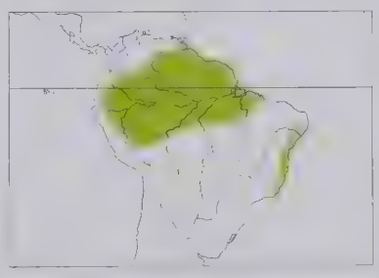
Descriptive notes. 13·5 cm; 11·5 g. Has buff supraloral area and ear-coverts, cinnamon forehead with olive-grey feather tips, dusky grey crown contrasting with olive-green upperparts; wings and tail duskier, two yellowish wingbars, yellowish edges of flight-feathers; throat whitish-buff, ochraceous-buff wash across breast, chest dull buff, belly bright yellow, tinged olive on flanks, creamy undertail-coverts; iris pale yellow-orange; bill broad, flat, relatively small, upper mandible black, lower mandible pale purple; legs dull purple (appearing grey at distance). Sexes alike. Juvenile not described. Voice. Call a distinct two-part, buzzy "wheeeeezzz-birrt" or "psi-trrrrrrrrr", given at long intervals, sometimes few buzzy notes appended; song a series of 5-7 well-enunciated "zhreee" notes, fairly similar to that of race *viridiceps* of *T. flaviventris* but notes somewhat longer and more wheezing.
Habitat. Restricted to middle levels, subcanopy and borders of *várzea* forest, below 400 m. Separated ecologically from congeners occurring at same sites; *T. poliocephalus* occupies canopy of *várzea* and second-growth forest, *T. assimilis* prefers *terra firme* forest, and *T. flaviventris* occupies *Cecropia*-dominated second growth and river islands.
Food and Feeding. Diet insects. Forages alone or, sometimes, with mixed flocks. Items obtained primarily by sallying to leaves.
Breeding. No information available.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Rare and local, although probably often overlooked within its small range. Recorded as far E as Amacayacu National Park, in extreme SE Colombia. In Ecuador, recorded at sites near R Napo, at Taracoa, Sacha Lodge, La Selva, and Kapawi Lodge and Ecological Reserve on upper R Pastaza, and probably in R Aguarico drainage. Occurs at ExplorNapo Lodge, in Peru. The species' rainforest habitat is as yet little disturbed, but its specialization on *várzea* and other riverine habitats may pose a problem as soon as areas are colonized by humans.
Bibliography. Clements & Shany (2001), Green (1998), Ridgely & Greenfield (2001), Schulenberg & Parker (1997), Stap (1990).

192. Yellow-margined Flycatcher

Tolmomyias assimilis

French: Platyrhynque à miroir **Spanish**: Picoplano Aliamarillo
German: Flügelspiegel-Breitschnabeltyrann
Other common names: Yellow-margined Flatbill; Zimmer's Flatbill (races E of Andes)

Taxonomy. *Rhynchocyclus assimilis* Pelzeln, 1868, Borba, Brazil.
Relationships within genus uncertain, pending completion of major genetic study. Race *flavotectus* considered by some authors to constitute a separate species on basis of disjunct distribution and vocal differences; further research required. Other races exhibit subtle variations in crown, breast and belly colours (breast becoming slightly darker in counterclockwise direction from the Guianas and NE Brazil back towards E Brazil S of Amazon (crown colour shows similar but slightly discordant pattern); further study needed on taxonomic limits within these races. Eight subspecies recognized.
Subspecies and Distribution.
T. a. flavotectus (Hartert, 1902) - E Costa Rica S to W Colombia (E to SW Bolívar and lower Cauca Valley) and NW Ecuador.
T. a. neglectus J. T. Zimmer, 1939 - E Colombia, SW Venezuela and NW Brazil (R Negro region of N Amazonas).
T. a. examinatus (Chubb, 1920) - SE Venezuela, the Guianas and NE Brazil (N bank of lower Amazon in N Pará and Amapá).
T. a. obscuriceps J. T. Zimmer, 1939 - SE Colombia (W Meta) S to NE Ecuador and NE Peru (E Loreto N of Amazon).
T. a. clarus J. T. Zimmer, 1939 - Peru (Amazonas, from just N of R Marañón, S to N Puno).
T. a. assimilis (Pelzeln, 1868) - C Brazil S of middle Amazon (from Tefé, in E Amazonas, E to R Tapajós, in W Pará).
T. a. paraensis J. T. Zimmer, 1939 - NE Brazil (E Pará, NW Maranhão).
T. a. calamae J. T. Zimmer, 1939 - SW Brazil (SE Amazonas) and N Bolivia.
Descriptive notes. 13-13·5 cm; 14·5-15 g. Big-headed, with dull white "spectacles", narrow white eyering broken in front. Nominate race has crown, nape and head side grey, tinged with olive, upperparts olive-green; wings dusky, conspicuous yellow margins on remiges and greater wing-coverts (pale panel at base of outer 3-4 primaries, faint wingbar); tail dusky; throat pale grey, becoming pale olive on breast and flanks, belly pale yellow; iris olive to dark brown; bill broad and flat, upper mandible black, lower mandible pale brownish, greyish or horn with darker tip; legs grey. Sexes similar. Juvenile resembles adult, but less grey on head, broader and less distinct margins of wing feathers tinged ochraceous. Races differ mainly in crown, breast and belly colours, but variations subtle (and crown colour varies with age): *neglectus* has olive crown, dull olive breast; *examinatus* is like previous but breast duller olive; *obscuriceps* has crown olive with a tiny bit of grey; *clarus* has sightly more grey in crown, brighter yellow belly; *calamae* has crown slightly darker than previous; *paraensis* has olive crown with only a little grey; *flavotectus* is more distinctive, differs from nominate in having discrete yellowish margins on greater wing-coverts (not forming wingbars), grey rather than olive breast. Voice. Song a leisurely series of 3-5 nasal buzzy whistles, ascending in pitch and shrill, "weeeuw weeeu weee" or "znuu znuu znuuu .znuuu-pík", given at long intervals; race *flavotectus* gives series of 3-5 similar notes, rather harsh and buzzy, with slight pause after first note, "zhweyk, zhwek-zhwek-zhwek-zhwek" (W Ecuador), "tsew, tseep tseep tseep" (Costa Rica) or "tsish, tsish tsish tsish" (Panama), typically a pause of several minutes before repeated again.



Habitat. Mid-level, subcanopy and edge of humid *terra firme*, *várzea* forest, tall second growth, and plantations; lowlands to 1000 m, locally to 1200 m on lower slopes of tepuis. Uses more mature forest than *T. sulphurescens* where the two co-occur; appears most abundant where that species is uncommon.
Food and Feeding. Diet mostly beetles (Coleoptera), worker ants (Hymenoptera), homopteran bugs (leafhoppers); small amounts of fruit (berries) taken. Stomach contents in SE Peru included 43 items, of which coleopterans 58%, hymenopteras 30% (ants 14%, wasps 16%), homopterans 5%, arachnids 5%, other 2%. Forages alone or in pairs, often joining mixed-species flocks of greenlets (Vireonidae), warblers (Parulidae) and tanagers (Thraupidae). Perches close to foliage in mid-storey and subcanopy, sometimes coming lower at edges or breaks (Costa Rica); has more horizontal posture than *T. sulphurescens*, and frequently cocks tail. Executes short upward sallies or hover-gleans to capture prey, often from undersides of leaves; occasionally pursues flushed insects. More active and noisy than *T. sulphurescens*.
Breeding. Apr-Jun in Costa Rica; nest-building in Apr in Panama; pair in breeding condition in May in Colombia. Nest a retort-like pear-shaped bag made of fine black fibres and fungal rhizomorphs, placed 9-21 m up (higher than *T. sulphurescens*), often near wasp nest. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common; probably often overlooked. Occurs in many national parks and other protected areas throughout its range, e.g. Darién National Park, in Panama, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Madidi and Noel Kempff Mercado National Parks and Beni Biosphere Reserve, in Bolivia, and Jaú and Tapajós National Parks, in Brazil. Much of its habitat remains in relatively pristine condition within its relatively large range. Probably locally extinct in areas where deforestation has been intense (e.g. SW Ecuador).
Bibliography. Anon. (1998a), Bates & Parker (1998), Begazo (1995), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Haverschmidt (1968), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Naka (2004), Novaes (1978a), Oren & Parker (1997), Peres & Whittaker (1991), Ridgely (1981), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Salaman (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Slud (1964), Snyder (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Tostain *et al.* (1992), Wetmore (1972), Willard *et al.* (1991), Willis (1980), Zimmer (1939c).

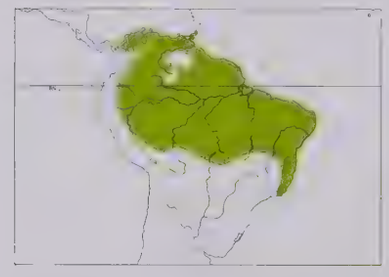
193. Grey-crowned Flycatcher

Tolmomyias poliocephalus

French: Platyrhynque poliocéphale **Spanish**: Picoplano Cabecigrís
German: Grauscheitel-Breitschnabeltyrann
Other common names: Grey-crowned Flatbill

Taxonomy. *Rhynchocyclus poliocephalus* Taczanowski, 1884, Nauta, Peru.
Relationships within genus uncertain, pending completion of major genetic study. Geographical boundaries of races poorly differentiated; *klagesi* possibly not a valid taxon, sometimes merged with *sclateri*; additional work required. Three subspecies tentatively recognized.
Subspecies and Distribution.
T. p. klagesi (Ridgway, 1906) - C & E Venezuela (N Amazonas, Bolívar, Delta Amacuro).
T. p. poliocephalus (Taczanowski, 1884) - SW Venezuela (S Amazonas), E & SE Colombia, E Ecuador, E Peru, and W Brazil (W Amazonas E to right bank of lower R Negro and Tefé).
T. p. sclateri (Hellmayr, 1903) - the Guianas through E Amazonian Brazil to N & C Bolivia; also isolated population in coastal E Brazil (Pernambuco S to Espírito Santo).

Descriptive notes. 12 cm; 11 g. Nominate race has small whitish supraloral stripe and faint indistinct eyering; crown and nape grey, contrasting with olive upperparts; wings blackish, wing-coverts and remiges sharply edged yellow (two yellowish wingbars, sometimes faint pale panel at base of primaries); tail dusky olive; throat greenish, breast and flanks olive, belly and vent pale yellow; iris pale yellow, pale grey or pale brown; bill broad and flat, upper mandible black, lower mandible dark with pale orange-flesh colour at base; legs grey. Sexes alike. Juvenile undescribed. Plumage differences of races quite subtle: *sclateri* differs from nominate in distinct pale grey throat, perhaps duller green back and paler yellow belly; *klagesi* appears intermediate between those two. Voice. Song a leisurely series of husky whistles that accelerate and strengthen towards end, "teeawe teeawe teeawe teeawe teeawe", at dawn repeated continuously for long periods, sometimes with interval of 1-2 seconds, at other times in a short series then a pause (Ecuador); *sclateri* a different series of 3-6 flatter, fife-like shrill "pfee" or "fwee" whistles with last 3 notes higher-pitched and inflected, reminiscent of song of Rufous-tailed Jacamar (*Galbula ruficauda*). Also in Amazonas a series of 5-15 low, soft inflected "pchoi" whistles.
Habitat. Middle and upper levels (Brazil), canopy and edge of humid *terra firme* forest, *várzea* forest and clearings; in Surinam, rather common on wooded sand ridges in coastal region, in coffee plantations, gardens, savanna forest. Mostly below 600 m, locally to 1000 m.
Food and Feeding. Recorded prey include bugs (Hemiptera) and coleopterans (of family Curculionidae). Forages singly or in pairs, usually accompanying mixed flocks of tanagers



(Thraupidae), ovenbirds (Furnariidae) and other tyrannids, from middle level up to canopy tops and emergent trees; perches more horizontally than *T. sulphurescens* and with tail partially cocked, and generally forages at higher levels than that species, usually also higher than *T. assimilis* (although sometimes in same flock). Small insects taken in upward-strike and hover-glean manoeuvres.
Breeding. Nests found in Jan and Jun in SE Colombia. Nest a hanging bag-like structure suspended 2-25 m above ground, often near wasp (Hymenoptera) nest. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common; often overlooked. Occurs in many national parks and other protected areas throughout its range, e.g. Tinigua National Park, in Colombia, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Madidi and Noel Kempff Mercado National Parks and Pilón Lajas Biosphere Reserve, in Bolivia, and Jaú and Tapajós National Parks, in Brazil. Has relatively large range within which much of its habitat remains in relatively good condition.
Bibliography. Bates & Parker (1998), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Dunning (1992), Friedmann (1948), Gilliard (1941), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Naka (2004), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Roda & Carlos (2003), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Zimmer (1939c).

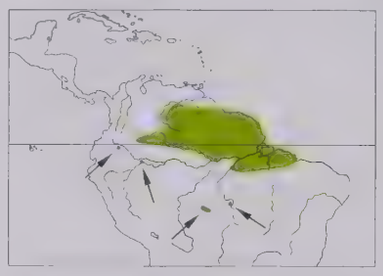
194. **Yellow-breasted Flycatcher**

Tolmomyias flaviventris

French: Platyrhynque à poitrine jaune **Spanish**: Picoplano Pechiamarillo
German: Gelbbauch-Breitschnabeltyrann
Other common names: Yellow-breasted Flatbill; Ochre-lored Flycatcher (N & E races *aurulentus*, *dissors* and *flaviventris*); Olive-faced Flycatcher (W Amazonian races *viridiceps*, *zimmeri* and *subsimilis*)

Taxonomy. *Muscipeta flaviventris* Wied, 1831, southern Bahia, Brazil.
Relationships within genus uncertain, pending completion of major genetic study. W Amazonian races (*viridiceps*, *zimmeri*, *subsimilis*) sometimes treated as a separate species on grounds of plumage and vocal differences. Taxonomic limits of all races, however, poorly delineated. Named taxon *borbae*, from Borba (R Madeira, in Brazil), considered an intergrade between *viridiceps* and nominate; *collingwoodi*, described from Trinidad, included within *aurulentus*. Six subspecies recognized.
Subspecies and Distribution.
T. f. aurulentus (Todd, 1913) - E Panama, N & E Colombia, N & C Venezuela, Trinidad and Tobago, the Guianas and N Brazil (R Branco E to N Pará and Amapá).
T. f. dissors J. T. Zimmer, 1939 - SW Venezuela and NE Brazil (N Pará near R Jamundá, and from W of R Tapajós E to R Tocantins and Marajó I).
T. f. flaviventris (Wied, 1831) - E Brazil S of Amazon (Maranhão S to Mato Grosso and Espírito Santo) and E Bolivia (NE Santa Cruz).
T. f. viridiceps (P. L. Sclater & Salvin, 1873) - SE Colombia, E Ecuador, E Peru and W Amazonian Brazil.
T. f. zimmeri Bond, 1947 - N & C Peru (San Martín S to Junín).
T. f. subsimilis Carriker, 1935 - SE Peru, SW Brazil and NW Bolivia.

Descriptive notes. 12-12·7 cm; 11·3 g. Distinctive. Nominate race is uniform yellowish-olive above, supraloral area and narrow eyering brighter and tinged ochre; wings and tail dusky, two yellowish wingbars, yellowish margins of remiges; bright yellow below, olive wash on throat and breast, paler on belly; iris dark brown to greyish-brown; bill broad and flat, usually all dark, sometimes paler base of lower mandible; legs blue-grey. Differs from congeners in brighter and yellower plumage, no grey in crown. Sexes similar. Juvenile resembles adult. Race *dissors* is slightly smaller than nominate; *aurulentus* is darker, yellow areas richer; *viridiceps* is duller olive and darker above, yellow or ochre tinge in face reduced or lacking, more olive on breast, has dark bill with pinkish base of lower mandible; *zimmeri* and *subsimilis* resemble last. Voice. Song ("nominate group") 3-5 loud penetrating "sweep" or "shreeeép" whistles, typically in sequences of three in Tobago, two in Trinidad, with pause of several seconds between notes; call a single "sweep". Call in W Amazonia ("*viridiceps* group") a faster series of 3-4 rising "cheeyp" notes.
Habitat. Widespread in dry to humid forest, woodland borders, shrubby areas, gallery forest, clearings, *restinga*, *caatinga*; in Amazonia mainly in riparian growth and *várzea* forest edge, with smaller numbers in *terra firme* forest. Also mangroves in Trinidad and the Guianas, and coffee plantations and gardens in Surinam. Lowlands to 1000 m.
Food and Feeding. Diet arthropods; also berries (Trinidad and Tobago). Recorded prey include coleopterans (of family Curculionidae), bugs (Hemiptera, including heteropterans) and craneflies (Tipulidae); stomach contents in SE Peru included 32 items, of which coleopterans 59%, hymenopterans 38% (ants 22%, wasps 16%), arachnids 3%. Forages alone or in pairs, mostly inside upper canopy of trees, sometimes quite low; sometimes joins mixed-species flocks, although often occurs in lightly wooded areas where mixed flocks do not form. Perches erect while searching for prey. Uses upward sally-strikes and sally-gleaning and hover-gleaning manoeuvres to seize prey from twigs or from undersides of leaves, afterwards dropping down to new perch; snaps mandibles audibly on capture.
Breeding. Apr-Jun in N Colombia, May-Sept in Venezuela (Apure, Guárico) and Trinidad, and May-Jun in Tobago. Nest, built by only one member of pair, a pear-shaped bag made from rootlets and fibres (black in most areas, pale in others), downward-facing entrance tube protruding from bottom on one side, suspended from thin branch often high up, often near wasp nest. Clutch 2-3 eggs; nestlings fed by both parents; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Widespread and fairly common to common. Especially common in Trinidad and Tobago, where this species occupies virtually all forest habitats; particularly numerous on Tobago. Recently reported from E Panama. Occurs in many national parks and other protected areas throughout its large range. Able to thrive in wide variety of wooded habitats, including converted ones.
Bibliography. Bates & Parker (1998), Bates *et al.* (1992), Begazo (1995), Buzzetti (2000), Carriker (1935), Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Dubs (1992), ffrench (1991), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes & Samad (2002), Herklots (1961), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Silveira *et al.* (2003), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Traylor (1977), Wetmore (1939), White (2002), Zimmer (1939c).



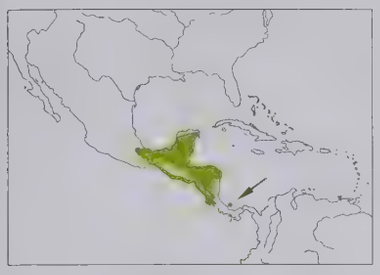
Genus *PLATYRINCHUS* Desmarest, 1805

195. **Cinnamon-crested Spadebill**

Platyrinchus saturatus

French: Platyrhynque à cimier orange **Spanish**: Picoplano Cresticanela
German: Zimtkopf-Breitschnabeltyrann

Taxonomy. *Platyrhynchus saturatus* Salvin and Godman, 1882, Merumé Mountains, Guyana.
Relationships within genus unclear, pending completion of major genetic study. Taxonomic limits of races uncertain; vocal differences reported between populations N and S of Amazon; additional research required. Two subspecies recognized.
Subspecies and Distribution.
P. s. saturatus Salvin & Godman, 1882 - S Venezuela (Amazonas, Bolívar), the Guianas, E Colombia (Vaupés, probably more widespread), N Brazil (upper R Negro, and from N Pará E to Amapá); and very locally NE Ecuador (N Sucumbíos) and NE Peru (Loreto).
P. s. pallidiventris Novaes, 1968 - Brazil S of Amazon, from lower R Tapajós E to N Maranhão, also locally in Mato Grosso (Alta Floresta) and E Rondônia.



Descriptive notes. 9·1-9·5 cm; 8·8-15 g, mean 10·6 g. Small, dull brownish spadebill with buffish-white supraloral spot and inconspicuous eyering. Nominate race has dark rufous-brown head with semi-concealed orange-rufous coronal patch; upperparts dark rufous-brown, wings similar, prominent dusky patch at base of primaries, remiges edged rufescent; white throat contrasts with olive-brown wash on breast and sides, and yellower belly; iris brown; bill broad and flat, black; legs pale pinkish-flesh. Sexes alike. Juvenile undescribed. Race *pallidiventris* has posterior crown feathers more orange-yellow than nominate, breast more olive, belly brighter yellow. Voice. Song (S of Amazon) a series of 3-6 notes, "ka-knee-knee-knee-knee", given in slow rattling or pulsating bursts; call (E Venezuela and Guyana) a distinct, sharp and nasal "chip-it"or "squik-ik", sometimes only the first note given.
Habitat. Undergrowth of *terra firme* forest, where it prefers areas of brushy undergrowth or dense stands of saplings; in W Amazonia, perhaps restricted to forests on sandy or other nutrient-poor soils, especially in black-water areas. Recorded up to 900 m.
Food and Feeding. Eats small arthropods. Reported as sometimes attending mixed-species understorey flocks, including those following swarms of army ants; also seen foraging in pairs. Forages by sitting still on low perch 1·5-3 m above ground in dense vegetation, scanning for prey; then either suddenly moves to new perch, or uses rapid upward-sally manoeuvres to scoop prey from undersides of leaves, after which it continues without pause to a new perch.
Breeding. No information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally uncommon to rare; perhaps often overlooked, as difficult to locate. Further fieldwork required in order to confirm true status; for example, considered widely distributed and not uncommon in Surinam.
Bibliography. Álvarez & Whitney (2003), Blake (1950), Clements & Shany (2001), Cory & Hellmayr (1927), Dunning (1993), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Meise (1954), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Novaes (1978a), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stouffer & Bierregaard (1995), Thiollay (1994), Thiollay & Jullien (1998), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer, J.T. (1939b), Zimmer, K.J. & Hilty (1997), Zimmer, K.J. *et al.* (1997).

196. **Stub-tailed Spadebill**

Platyrinchus cancrominus

French: Platyrhynque à queue courte **Spanish**: Picoplano Rabón
German: Kurzschwanz-Breitschnabeltyrann
Other common names: Mexican Spadebill

Taxonomy. *Platyrhynchus cancrominus* P. L. Sclater and Salvin, 1860, Choctum, Guatemala.
Relationships within genus unclear, pending completion of major genetic study. Has sometimes been considered conspecific with *P. mystaceus*, but the two behave as separate species in Costa Rica. Birds from Yucatán Peninsula sometimes separated as race *timothei* and those from El Salvador S to NW Costa Rica as race *dilutus*, but poorly differentiated from other populations; additional work required in order to assess taxonomic status of these forms. Treated as monotypic.
Distribution. SE Mexico (from S Veracruz, Tabasco, Chiapas and Yucatán Peninsula) S to Nicaragua and W Costa Rica; recently found also in NW Panama (Bocas del Toro Archipelago).
Descriptive notes. 9·9·5 cm; 10-12 g. Male has bold facial pattern created by pale yellow supraloral patch, eyering, auricular patch below eye and arching postocular stripe, contrasting with dark blackish-brown lores, stripe beneath front of eye and patch on rear auriculars (in front of pale postocular stripe); crown and side of head greyish-brown, semi-concealed yellow coronal patch; upperparts olive-brown; wings dusky, feathers with cinnamon-brown edgings; tail small, stubby, brown; throat white, contrasting with tawny-buff or brown breast, pale yellow belly and undertail-coverts; iris dark; bill broad and flat, upper mandible black, lower mandible pale flesh-coloured; legs flesh-pink. Female lacks yellow coronal patch. Juvenile has facial pattern less distinct, yellow coronal patch lack-

ing, browner above with dark feather fringes, fulvous wingbars, pale greyish-buff throat and breast shading to white on belly. Voice. Dawn song a nasal, rapid, rolled trill alternated with sharp calls, "ki-di-di-di-rrril, ki-di-di-di-drri-l-l sy-iik"; call a sharp nasal twitter of 2-3 notes, "ki-dih" or "ki-dih-dih", also a rolled nasal trill, "pirrrirrr"; partners frequently call back and forth to each other.

Habitat. Low to middle levels of shady understorey in humid evergreen forest, semi-deciduous forest, gallery forest and dry forest; sea-level to 1300 m (Costa Rica), in Mexico to 1500 m.

Food and Feeding. Diet includes homopteran bugs, ants (Hymenoptera), beetles (Coleoptera), spiders (Araneae); indirect evidence of fruit consumption in Mexico. Forages alone or in pairs; not known to attend mixed flocks, but reported as foraging at swarms of army-ants (*Eciton burchelli*) in Mexico (Los Tuxtlas). Forages from ground or low perches, scanning surrounding foliage; uses rapid upward-sally manoeuvres to scoop prey from undersides of leaves or twigs; sometimes searches leaf litter on ground, without manipulating leaves.

Breeding. May in Costa Rica. Nest a cone-shaped thin-walled cup constructed from fine grasses, bark strips and bits of leaves, lined with black fungal rhizomorphs, placed firmly in vertical fork of understorey shrub. Clutch 2 eggs; no information on incubation and fledging periods.

Movements. Resident.

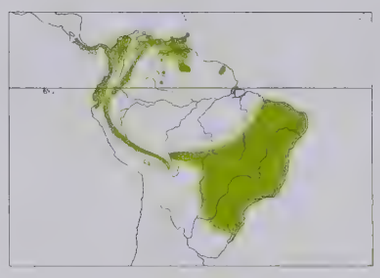
Status and Conservation. Not globally threatened. Common to fairly common in Mexico and Bocas del Toro in Panama, uncommon and local in Costa Rica; fairly common in Panama, where it was found on all six of the larger islands at entrance of Laguna de Chiriquí. Occurs in several protected areas, including Río Bravo Conservation and Management Area, Columbia River Forest Reserve and Lamanai Archaeological Reserve, in Belize, and Tarcol Lodge, Carara Biological Reserve and Río Negro Jaguar Reserve, in Costa Rica.

Bibliography. Anon. (1998a), Binford (1989), Brodkorb (1943), Coates-Estrada & Estrada (1989), Cory & Hellmayr (1927), Dearborn (1907), Gómez de Silva *et al.* (1999), González-García (1993), Herrera *et al.* (2003), Howell & Webb (1995a), Kricher & Davis (1992), Land (1970), Lee Jones (2004), Lowery & Dalquest (1951), Meise (1954), Monroe (1968), Olson (1993), Paynter (1957), Ridgely & Gwynne (1989), Ridgway (1907), Rowley (1984), Slud (1964, 1980), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Wetmore (1943, 1944).

197. White-throated Spadebill

Platyrinchus mystaceus

French: Platyrhynque à moustaches **Spanish**: Picoplano Bigotudo
German: Gelbscheitel-Breitschnabeltyrann
Other common names: Yellow-crested Spadebill ("nominate group")



Taxonomy. *Platyrhynchos mystaceus* Vieillot, 1818, Paraguay.

Relationships within genus unclear, pending completion of major genetic study. Has sometimes been considered conspecific with *P. cancrominus*, but the two behave as separate species in Costa Rica. Races fall into two different types, the Central American-Andean "*albogularis* group" (including *perijanus* and *zamorae*) and the "nominate group" of lowlands (E from N Venezuelan *insularis* and tepui races and from N Bolivia); *partridgei* apparently intermediate between the two. Further work necessary in order to clarify taxonomic limits of these groups, as well as relationships within and between races with dark lower mandible (former group) and those with pale lower mandible ("nominate group"). Specimen from N Bolivia (Trinidad, in Beni) may belong to race *bifasciatus*, thus extending latter's range far to W. Fourteen subspecies recognized.

Subspecies and Distribution.

P. m. neglectus (Todd, 1919) - Costa Rica, Panama, N & C Colombia (R Truandó, Santa Marta region, Boyaca) and NW Venezuela (W Táchira).
P. m. perijanus Phelps, Sr & Phelps, Jr, 1954 - Sierra de Perijá, on Colombia-Venezuela border.
P. m. albogularis P. L. Sclater, 1860 - W Colombia (Pacific slope of W Andes, Cauca Valley, head of Magdalena Valley) and W Ecuador.
P. m. zamorae (Chapman, 1924) - E Ecuador S along Andes to SE Peru (S to W Madre de Dios).
P. m. partridgei Short, 1969 - extreme SE Peru (S Puno) and W & C Bolivia (La Paz, Cochabamba, SW Santa Cruz).
P. m. insularis J. A. Allen, 1889 - N Venezuela (Falcón and Lara E to Sucre, and Orinoco Valley from NW Bolívar E to Delta Amacuro), Trinidad and Tobago, and locally in W Guyana and French Guiana.
P. m. imatacae J. T. Zimmer & Phelps, Sr, 1945 - Sierra de Imataca, in NE Bolívar (E Venezuela).
P. m. ptaritepui J. T. Zimmer & Phelps, Sr, 1946 - Sororopán-tepui, Ptari-tepui and Aprada-tepui, in SE Bolívar (SE Venezuela).
P. m. duidae J. T. Zimmer, 1939 - S & SE Venezuela (Cerros Yaví, Duida and Roraima) and extreme N Brazil (N R Branco).
P. m. ventralis Phelps, Sr & Phelps, Jr, 1955 - extreme S Venezuela (Cerro de la Neblina) and adjacent NW Brazil.
P. m. bifasciatus J. A. Allen, 1889 - S Brazil (C Mato Grosso E to C Goiás), possibly also N Bolivia (Beni).
P. m. mystaceus Vieillot, 1818 - SE Brazil (S Mato Grosso, C Paraná and W Santa Catarina S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones, Corrientes).
P. m. cancromus Temminck, 1820 - E Brazil (interior Maranhão E to Ceará and N Bahia, S to E Paraná and E Santa Catarina).
P. m. niveigularis Pinto, 1954 - coastal forests of NE Brazil (Paraíba S to Alagoas).

Descriptive notes. 9·5-10 cm; 8·1-12 g. Small, big-headed and stub-tailed spadebill with bold facial pattern. Male nominate race has pale buff-yellow supraloral patch, eyering, auricular patch below eye and arching postocular stripe, contrasting with dark blackish-brown lores, stripe beneath front of eye and patch on rear auriculars (in front of pale postocular stripe); dark olive-brown on crown, semi-concealed yellow coronal patch; upperparts, wings and stubby tail olive-brown; throat whitish or pale yellow, underparts creamy buff to ochraceous, sometimes washed tawny to olive on breast and sides, belly tinged ochre; iris dark; bill broad and flat, upper mandible black, lower mandible pale; legs pale flesh-coloured or grey. Female is similar to male, but coronal patch small or absent. Juvenile lacks yellow coronal patch, is brighter and more rufescent above, throat and breast pale greyish-brown, belly buffish-white. Race *cancromus* is very similar to nominate; *niveigularis* has pure white throat; *insularis* differs from nominate in being more greenish-olive (less brownish) above, paler and whiter on belly, with more distinct olive-buff breastband; *duidae*

is like previous, but darker upperparts, more ochre-tinged underparts; *ptaritepui* has paler crown patch, all-dark bill; *ventralis* has brighter yellow coronal patch, much darker ochre underparts; *imatacae* has grey-tinged crown, paler underparts, breast yellowish-buff, abdomen yellowish-white; *bifasciatus* is larger than nominate, strongly greenish above, with distinct wingbars, buffy yellow below; *albogularis* differs from nominate in having dark lower mandible with pale tip, more pure white throat contrasting more with breast, whiter belly; *neglectus* and *zamorae* are similar to last; *perijanus* differs from previous in olivaceous (instead of brownish) upperparts; *partridgei* is essentially intermediate in plumage between "nominate group" and "*albogularis* group", but has all-dark bill as in latter. Voice. Song a high, thin, rattling trill, "pe'e'e'e'e'e'e'e'e'e'eet", rising slightly and then descending, sometimes preceded by abrupt "squek" note; frequently heard call a short and sharp "squeep", sometimes doubled or given in a series. Wing-whir like that of a manakin (Pipridae) during flight display.

Habitat. Undergrowth of a variety of habitats, including humid lowland and montane forests, dry forest, gallery forest, tall secondary woodland; sometimes in tangled brushy areas or bamboo thickets along forest borders. Sea-level to 2150 m; 700-2150 m in Costa Rica, 750-1800 m in Panama, 900-2000 m in Colombia, 1000-2000 m on E slope of Andes in Ecuador, and 600-2000 m on W slope in Ecuador and E slope in Peru.

Food and Feeding. Arthropods. Stomach contents in SE Peru included 32 prey items, of which beetles (Coleoptera) 46%, hymenopterans 15% (ants 6%, wasps 9%), bugs (Hemiptera) 12%, arachnids 9%, orthoptera 6%, homopterans 6%, other 6%. Occurs in pairs, with individuals well separated; generally does not join mixed-species flocks, but reported to do so in gallery forest in Venezuelan *llanos* and in second-growth forest in Brazil (Rio de Janeiro). Perches 0·3-5 m up in dense undergrowth for long periods, scanning surrounding foliage, or changes perch; uses rapid upward-sally manoeuvres to scoop prey from undersides of leaves or twigs, capture accompanied by audible bill-snap.

Breeding. Mar-May in Costa Rica, May-Jul in N Colombia and Dec in E; May-Jul in Trinidad, Jun in Tobago. Male, when excited, sings with yellow feathers of coronal patch erected in a fan; has flight display accompanied by wing-whir. Nest in Costa Rica a smooth cone-like cup of black fungal fibres, pale fibres, and dead leaves that drape below bottom, and fragment of snakeskin; in Trinidad a deep cup of dead grasses and pale fibres bound with cobweb, lined with black fibres; placed 1-3 m (in Trinidad 0·5-0·7 m) above ground in upright fork of shrub or sapling. Clutch 2 eggs; no information on incubation and fledging periods.

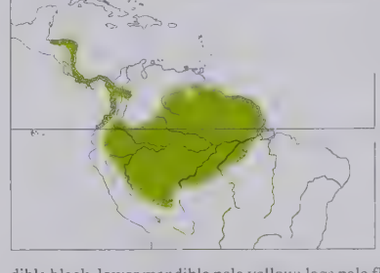
Movements. Resident.

Status and Conservation. Not globally threatened. Common to fairly common, but perhaps less numerous at higher altitudes of range; often overlooked unless mist-netted. Occurs in many national parks and other protected areas throughout its rather large range. Has possibly suffered from deforestation in lowlands.

Bibliography. Anon. (1998a), Begazo (1995), Bond *et al.* (1989), Brooks *et al.* (1993), Canevari *et al.* (1991), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Davis (1945, 1946), Davies *et al.* (1994), ffrench (1991), Hayes (1995), Hayes & Samad (2002), Hilty (1997, 2003), Hilty & Brown (1986), Lowen *et al.* (1996), Meise (1954), Meyer de Schauensee & Phelps (1978), Miller (1963), Narosky & Salvador (1998), de la Peña (1988), Pople *et al.* (1997), Remsen *et al.* (1991), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), do Rosário (1996), Salaman (1994), Short (1969), Sick (1993, 1997), Silveira *et al.* (2003), Slud (1964), Snow (1985a), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh & Weske (1975), Thiollay (1994), Tostain *et al.* (1992), Wetmore (1972), White (2002), Williams & Tobias (1994), Zimmer (1930, 1939b).

198. Golden-crowned Spadebill

Platyrinchus coronatus



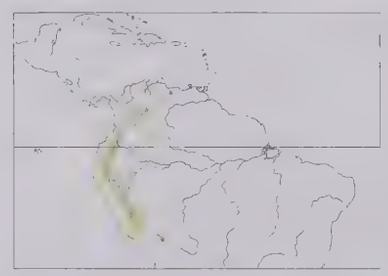
French: Platyrhynque à tête d'or **Spanish**: Picoplano Coronado
German: Goldkappen-Breitschnabeltyrann

Taxonomy. *Platyrhynchus coronatus* P. L. Sclater, 1858, River Napo, Ecuador.

Relationships within genus unclear, pending completion of major genetic study. True taxonomic status of races uncertain; further research required. Three subspecies recognized.

Subspecies and Distribution.

P. c. superciliaris Lawrence, 1863 - Honduras S to N & W Colombia (Caribbean lowlands, N base of Andes to middle Magdalena Valley in W Santander, and Pacific lowlands) and NW Ecuador (S to Manabí).
P. c. coronatus P. L. Sclater, 1858 - S Venezuela (Amazonas), SE Colombia (S from W Caquetá and NE Amazonas) and E Ecuador s to E Peru (S Loreto, E Pasco), NW & W Brazil (upper R Negro and, S of Amazon, E to R Xingu area and S to NW Mato Grosso) and N Bolivia (S to La Paz).
P. c. gumia (Bangs & T. E. Penard, 1918) - SE Venezuela (C & E Bolívar), the Guianas and adjacent N Brazil (upper R Branco E to Amapá).



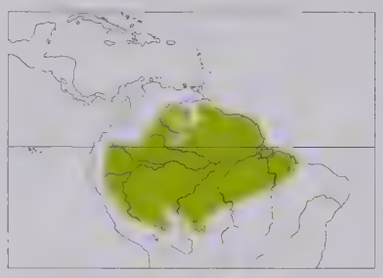
Descriptive notes. 8·5-9 cm; 8-9 g. Small spadebill with bold facial pattern, prominent rictal bristles. Has pale buff-yellow (or olive-tinged) supraloral band, eyering, auricular patch below eye and arching postocular stripe, which contrast with dark blackish-brown lores, stripe beneath front of eye and rear auricular patch (in front of pale postocular stripe); rest of head olive, broad orange-rufous on crown bordered laterally with black, semi-concealed yellow coronal patch; upperparts, wings and tail olive; throat pale whitish-yellow, underparts pale yellow, olive wash or streaks on breast; iris dark; bill broad and flat, upper mandible black, lower mandible pale yellow; legs pale flesh-coloured. Sexes similar, but female's coronal patch more orange. Juvenile has paler facial markings and underparts, entirely brownish-olive crown, greyish-olive upperparts, ochraceous-tinged edges of wing-coverts and remiges. Races all very similar; *superciliaris* has brighter yellow underparts than nominate; *gumia* is slightly smaller than others, has brighter yellow belly. Voice. Song a quiet insect-like trill, "se'e'e'e'e'e'r'r'r'r'r'e'e'e" or "bzee-eee-eéep", descends in pitch slightly in middle and then rises at end, 1-3 sharp "pip" notes

sometimes added; call an insect-like chirp (like that of an orthopteran), repeated 2-3 times. Also audible mechanical wing-whir in display-flight.
Habitat. Dark understorey of humid forest (both *terra firme* and *várzea*) and adjacent tall second growth, in lowlands and foothills. Mainly below 500 m, but recorded to 700 m on Caribbean slope and to 1200 m on Pacific slope of Costa Rica, to 1500 m in Venezuela and to 1650 m in C Ecuador.
Food and Feeding. Diet includes beetles (Coleoptera), caterpillars, small grasshoppers (Orthoptera), spiders (Araneae), and other small arthropods. Occur in pairs throughout year; in Costa Rica frequently joins mixed-species understorey flocks, but rarely seen to accompany swarms of army ants. Forages by perching 1-5 m up in open shady understorey, scanning surrounding foliage for prey; makes rapid upward-sally manoeuvres for short to long distances (to c. 10 m) from perch, scooping prey from undersides of leaves or twigs.
Breeding. Apr-Jun in Costa Rica and Jul in Panama; in Colombia, Jan-Apr in NW and Aug in SE. Makes short display-flights between perches, accompanied by audible wing-whirs. Nest a cup of plant fibres, tree-fern scales and fungal rhizomorphs, bound by spiderweb, lined with fine fibres, outside decorated with moss and spider egg cases, sometimes with messy "tail" of debris, nest cup somewhat reminiscent of that of a hummingbird (Trochilidae); placed 1-4 m up in upright fork of shrub or sapling. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common or locally common; probably often overlooked. Occurs in many national parks and other protected areas throughout its range, e.g. from Tarcol Lodge and Río Negro Jaguar Reserve, in Costa Rica, and Darién National Park, in Panama, S to Beni and Pilón Lajas Biosphere Reserves, in Bolivia. Studies at Manaus, in Brazil, have shown that forest fragmentation has negative effects on the species' population density. Probably locally extinct wherever deforestation has been intense, e.g. in lowlands of W Chiriquí, in Panama; may have disappeared also from the small Río Palenque Science Centre, in Ecuador. On the other hand, much suitable habitat remains in relatively good condition within its large range.
Bibliography. Anon. (1998a), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Karr & Freemark (1983), Karr *et al.* (1990), Meise (1984), Meyer de Schauensee & Phelps (1978), Monroe (1968), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Salaman (1994), Sherry (1984), Sick (1993, 1997), Skutch (1960, 1985), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Stouffer & Bierregaard (1995), Terborgh *et al.* (1990), Thiollay (1994), Tostain *et al.* (1992), Wetmore (1972), Willis (1980), Zimmer (1930, 1939b).

199. **Yellow-throated Spadebill**
Platyrinchus flavigularis

French: Platyrhynque à gorge jaune **Spanish**: Picoplano Gorgiamarillo
German: Gelbkehl-Breitschnabeltyrann

Taxonomy. *Platyrhynchus flavigularis* P. L. Sclater, 1862, Nova Granada, "Bogotá" = Albán, Cundinamarca, Colombia.
Relationships within genus unclear, pending completion of major genetic study. Distribution apparently very patchy but little known, and degree of disjunction uncertain; further work required in order to confirm true taxonomic status of races. Two subspecies recognized.
Subspecies and Distribution.
P. f. vividus Phelps, Sr & Phelps, Jr, 1952 - W Venezuela (Sierra de Perija, Andes of SE Lara and SE Táchira; probably also coastal cordillera in SE Carabobo).
P. f. flavigularis P. L. Sclater, 1862 - E Andes of Colombia (W side in W Cundinamarca and Huila), E Ecuador (E slope from W Napo S to Zamora-Chinchipe) and E Peru (N Amazonas S to Cordillera Vilcabamba, in Cuzco).

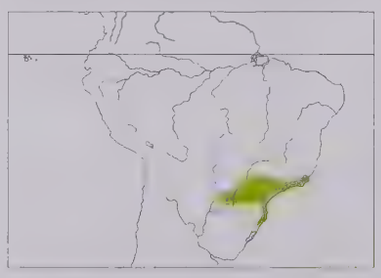


Descriptive notes. 9·5-10·2 cm. Has bright rufous-brown head, yellowish loral spot, large white coronal patch (semi-concealed) with black feather tips (not visible in the field); upperparts olive, duskier on wings and stubby tail; pale yellow below, brightest on throat, smudgy olivaceous breastband; iris dark; bill broad (11 mm) and flat, blackish above, pale below (turning bright yellow towards base); legs flesh-pink. Sexes alike. Juvenile undescribed. Voice. Call a sharp "peeeyr", slowly repeated at intervals of 4-5 seconds.
Habitat. Undergrowth of montane forest. In Ecuador favours areas with relatively open understorey, especially on ridges where soil thin and vegetation less developed. Recorded at 1250-2100 m in Venezuela, 1800-2300 m in Colombia, 750-1700 m in Ecuador.
Food and Feeding. Little known. Diet probably arthropods. Difficult to observe; often perches motionless in the open for extended periods.
Breeding. Birds in breeding condition in Apr-Jun in Venezuela. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to uncommon and local throughout most of range; perhaps often overlooked. Possibly locally fairly common in Venezuela (W Zulia); record from SE Carabobo requires verification. Rare and apparently declining in Colombia. Few records from Ecuador, where it may be "near-threatened". Rare in Peru. Conservation status probably merits re-assessment.
Bibliography. Canaday (2002a), Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Davies *et al.* (1994), Hilty (2003), Hilty & Brown (1986), Meise (1954), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Rasmussen *et al.* (1996), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins *et al.* (1987), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Zimmer (1930).

200. **White-crested Spadebill**
Platyrinchus platyrhynchos

French: Platyrhynque à cimier blanc **Spanish**: Picoplano Crestiblanco
German: Silberkopf-Breitschnabeltyrann

Taxonomy. [*Todus*] *platyrhynchos* J. F. Gmelin, 1788, locality unknown, possibly Surinam.
Relationships within genus unclear, pending completion of major genetic study. Additional work needed in order to clarify taxonomic limits of races. Four subspecies recognized.
Subspecies and Distribution.
P. p. platyrhynchos (J. F. Gmelin, 1788) - E Colombia (E Guainía and E Vaupés, probably also E Vichada), S Venezuela (Amazonas, Bolívar), the Guianas, and N Amazonian Brazil (upper R Negro E to R Branco and N Pará).
P. p. senex P. L. Sclater & Salvin, 1880 - E Ecuador, E Peru, extreme W Brazil (R Juruá) and N Bolivia (S to La Paz, SW Beni, and NE Santa Cruz).
P. p. nattereri Hartert & Hellmayr, 1902 - SC Amazonian Brazil, from lower R Purús E to upper R Madeira and R Jiparaná (E Amazonas).
P. p. amazonicus Berlepsch, 1912 - E Amazonian Brazil S of Amazon, from left bank of R Tapajós E to N Maranhão.



Descriptive notes. 10·5-11·5 cm; 11·5-13 g. Large-headed, stub-tailed flycatcher; bill extremely broad (12 mm), broadest of genus. Nominate race has grey head, darker on crown and paler on side, with semi-concealed white coronal patch, pale buffy supraloral spot; contrasting russet-brown upperparts; wings and tail dusky brown; throat white, breast and belly uniform bright ochraceous; iris dark; bill very broad and flat, upper mandible black, lower mandible pale; legs pinkish-yellow. Sexes similar, female with white coronal patch smaller than male's. Juvenile undescribed. Race *senex* is similar to nominate, but crown somewhat paler, brown of upperparts less rich and less dark; *nattereri* has slightly paler and yellower belly; *amazonicus* has ochraceous colour of underparts not so bright and more restricted to breast, with belly much paler and yellower than nominate. Voice. Song a thin buzzy or burry trill that ascends and then descends in pitch, e.g. as "pr're're'e'e'e'e'é'é'é''r'r'r'r'r'r'r" or "bree-ee-ee-ee-ee-ee-ee-ee-cuw", sometimes with sharp "squek" note at end; most frequent call, given from open perch, a sharp, loud and explosive "skeeuw" or "péép", sometimes repeated at intervals of 1-5 seconds and reminiscent of a *Sclerurus* leaftosser (Furnariidae). Also mechanical wing-whir, like that of a manakin (Pipridae), during display-flight.
Habitat. Open understorey of humid *terra firme* forest; most numerous in forests on sandy soils. Mostly below 500 m, but recorded to 900 m in Peru.
Food and Feeding. Small arthropods; bugs (Hemiptera), including homopterans of family Fulgoridae, recorded in diet in Surinam. Occurs in pairs; not seen to attend mixed-species flocks, but seems to be more active in their midst. Forages by sitting still on perch 2-5 m up (somewhat higher and in more open areas than congeners) above dense vegetation; then either makes rapid upward-sally manoeuvres to scoop prey from undersides of leaves, after which it continues without pause to a new perch, or suddenly moves to new perch over 1 m away.
Breeding. Recorded (without specific details) in Nov in Surinam; male in breeding condition in May in SE Colombia. Display-flight between perches at steep downward angle, accompanied by mechanical wing-whirring. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally rare throughout most of range, but could be overlooked; local in NW Amazonia, and uncommon to locally fairly common in Venezuela. Few records from E Ecuador. Occurs in several national parks and other protected areas, e.g. near Kapawi and La Selva Lodges, in Ecuador, and in Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Noel Kempff Mercado National Park, in Bolivia, and Jaú and Tapajós National Parks, in Brazil. Although this is in general a scarce species, much of its habitat remains in relatively undisturbed condition.
Bibliography. Allen (1995), Bates & Parker (1998), Clements & Shany (2001), Cory & Hellmayr (1927), Descourtilz (1983), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Meise (1954), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olivares (1964), Oren & Parker (1997), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Stouffer & Bierregaard (1995), Terborgh *et al.* (1990), Tostain (1980), Tostain *et al.* (1992), Willard *et al.* (1991).

201. **Russet-winged Spadebill**
Platyrinchus leucoryphus

French: Platyrhynque à ailes rousses **Spanish**: Picoplano Alirrufo
German: Rostflügel-Breitschnabeltyrann

Taxonomy. *Platyrinchos leucoryphus* Wied, 1831, Itapemirim, Espírito Santo, Brazil.
Relationships within genus unclear, pending completion of major genetic study. Monotypic.
Distribution. SE Brazil (Paraná and São Paulo E to C Espírito Santo, S to NE Santa Catarina and Rio Grande do Sul) and adjacent E Paraguay (Canindeyú S to Paraguarí, Caazapá and Itapúa) and extreme NE Argentina (Iguazú National Park, in N Misiones).

Descriptive notes. 12·5 cm; 17 g. Largest spadebill. Has olive-brown crown with semi-concealed white coronal patch; bold facial pattern created by pale buff-white to yellowish supraloral spot, eyering, auricular patch below eye and arching postocular stripe, contrasting with dark brown lores, stripe beneath front of eye and rear auricular patch (in front of pale postocular stripe); upperparts olive-brown; wings brown, wing-coverts and remiges broadly edged russet; tail long, brown; throat white, contrasting olive-brown wash on breast and sides, dull yellow or white belly; iris dark brown; bill broad and flat, upper mandible black with yellow edges, lower mandible yellow; legs pale orange to flesh-coloured. Sexes similar. Juvenile undescribed. Voice. Song a weak, thin, buzzy trill, "bzee-eee-eép", pattern similar to that of *P. mystaceus*; call a loud "ééo", similar to that of *Leptopogon amaurocephalus*.
Habitat. Undergrowth of humid forest and medium levels of mature second growth, both in coastal mountains and lowlands and in interior tableland forests; in Paraguay, seems to prefer forest having many small saplings and lianas for perching, but a shady open understorey. Recorded up to at least 1000 m.
Food and Feeding. Eats small arthropods. Adult seen to take green katydids (Tettigoniidae), and nestlings observed while being fed with katydids, cockroaches (Blattodea), moths (Lepidoptera)

and spiders (Araneae). Usually solitary; one record of an individual attending mixed-species flock in forest undergrowth in Brazil. Sits still on perch in crown of small tree (3-8 m), scanning surrounding foliage for prey; then either suddenly moves to new perch, or uses rapid upward-sally or diagonal-sally manoeuvres to scoop prey from undersides of leaves, after which it continues without pause to a new perch.

Breeding. Sept-Nov. Cup-shaped nest, outer wall composed of fragments of dry leaves (bamboo leaves in Paraguay) interwoven with fibrous lichens, exterior "decorated" with small pieces of bark or white silk (probably from spider's web), suspended "tail" of fibrous lichens and bamboo leaves, neatly woven inner wall of fibrous lichens with lining of semi-decomposed small leaves, or completely lined with black fungal rhizomorphs; external diameter 6 cm, depth 4 cm (not including pendant dry leaves); placed 2·5-4·5 m above ground in fork of small sapling. Clutch 2 eggs; no information on incubation and fledging periods; at one nest with two chicks, these were fed 2·9 meals/nestling/hour.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Rare, and possibly local. Formerly listed as Vulnerable; recent change in conservation status based on accounts of an apparent tolerance of second growth, and apparent increase in records following improved knowledge of its vocalizations. Recent surveys in Paraguay, however, have failed to find new populations of the species, and documented populations are now known to be less extensive than was originally postulated; remains inexplicably rare in Argentina. Occurs in Iguaçu National Park, Augusto Ruschi Biological Reserve, Intervales State Park and at least 13 other nominally protected areas in Brazil, where this species is protected by law; also in Caaguazú and San Rafael National Parks and Mbaracayú Forest Nature Reserve, in Paraguay, and Iguazú National Park, in Argentina. Despite some tolerance of second growth, appears to be largely dependent on primary forest and to occur naturally at low densities; extensive and continuing deforestation across most of its range may have caused a population decline and led to its disappearance from previously occupied locations. Less than 20% of original extent of lowland Atlantic Forest remains intact, and surviving forest, even within protected areas, suffers from agricultural conversion, mining, urbanization, industrialization, and associated road-building; in Paraguay alone, 38% of forests disappeared between 1984 and 1991, less than 10% is now left, and significant forest loss occurs even within San Rafael National Park. Returning this species to its previous conservation status of Vulnerable may be appropriate.

Bibliography. PLATE 29

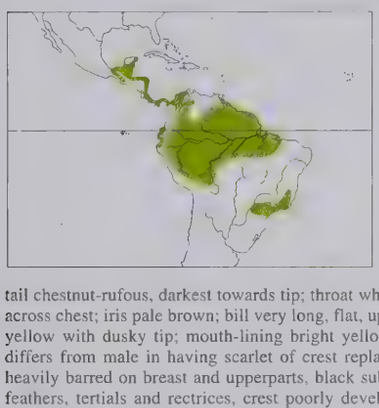
inches 3

cm 8

Genus *ONYCHORYNCHUS*



J. G. Fischer von Waldheim, 1810

202. **Royal Flycatcher**

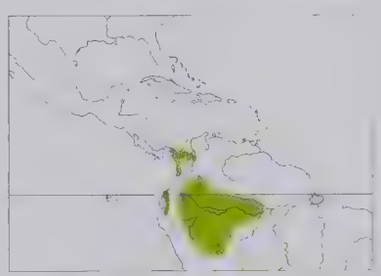
Onychorynchus coronatus

French: Porte-éventail roi **German**: Kronentyrann **Spanish**: Mosquero Real
Other common names: Crowned Flycatcher; Northern Royal Flycatcher (*mexicanus*, *fraterculus*); Amazonian Royal Flycatcher (*coronatus*, *castelnaui*); Pacific Royal Flycatcher (*occidentalis*); Atlantic Royal Flycatcher (*swainsoni*)

Taxonomy. *Muscicapa coronata* Statius Muller, 1776, Cayenne.
Thought to be closest to *Platyrinchus* on basis of cranial and syringeal characters. Despite apparent similarity in voice across range, is sometimes split into four separate species on grounds of plumage variation and allopatric distributions, one in N (*mexicanus*, *fraterculus*), one in Amazonia (nominate, *castelnaui*), one in W (*occidentalis*) and one in E (*swainsoni*); further research required in order to determine validity or otherwise of such treatment. Within these groups racial variation doubtful; in particular, birds intermediate between *mexicanus* and *fraterculus* occur in Costa Rica and Panama. Six subspecies recognized.
Subspecies and Distribution.
O. c. mexicanus (P. L. Sclater, 1857) - S & E Mexico S to Panama.
O. c. fraterculus Bangs, 1902 - N Colombia and NW Venezuela.
O. c. occidentalis (P. L. Sclater, 1860) - W Ecuador (S to El Oro) and extreme NW Peru (Tumbes).
O. c. coronatus (Statius Muller, 1776) - S & E Venezuela, the Guianas and NE Brazil.
O. c. castelnaui Deville, 1849 - E of Andes, from SE Colombia and extreme S Venezuela (S Amazonas) S to NE Peru, much of Amazonian Brazil and N Bolivia.
O. c. swainsoni (Pelzeln, 1858) - SE Brazil (Bahia and Minas Gerais S to Paraná and Rio de Janeiro).

Descriptive notes. 15-17·5 cm; 13-21 g. Distinctive flycatcher with long rictal bristles; large crest, usually held flat, protrudes from rear of head, creating "hammerhead" appearance, when fully extended forms large, semicircular, forward-facing fan. Male nominate race has crest feathers shiny scarlet with a spot of black and steel-blue at tips (small bits of colour occasionally show through when crest held flat); buffy supraloral stripe and broken eyering, contrasting dark lores; mostly dark brown above, fine buff and black barring on lower back, rump cinnamon-rufous, wings with buff spots on tips of wing-coverts and tertials; tail chestnut-rufous, darkest towards tip; throat whitish, underparts warm buff, fine brown barring across chest; iris pale brown; bill very long, flat, upper mandible blackish, lower mandible horn to yellow with dusky tip; mouth-lining bright yellowish-orange; legs pale yellow-orange. Female differs from male in having scarlet of crest replaced with yellow or orange. Immature is more heavily barred on breast and upperparts, black subterminal bands outlining buffy fringe on back feathers, tertials and rectrices, crest poorly developed. Races vary mainly in size, bill and tail lengths, extent of barring on breast, colour of crest, and brightness of plumage (especially rump and tail): *castelnaui* is very similar to nominate, perhaps smaller and with less barring above; *swainsoni* is paler generally, with bright ochraceous-buff underparts and no breast markings; *occidentalis* is quite distinct, even brighter and paler than previous, upperparts and wings a warm tawny-brown, tail brighter and paler tawny; *mexicanus* has the crest orange-red in male and orange in female, rump and tail-coverts cinnamon-buff, tertials edged pale cinnamon, tail tawny-orange shading to brownish at tip, underparts buffy yellow; *fraterculus* perhaps has fewer markings on breast, paler cinnamon rump and tail. Voice. Usually quiet. A loud, mellow and hollow, upslurred "see-yuk" or "curr-lep" whistle, reminiscent of a *Galbula* jacamar or a *Manacus* manakin; song a descending, slowing series of 5-8 higher, sharper, plaintive whistles preceded by shorter introductory note, "whi, peeu peeu peeu peeu peeu" or "wh, wheeu wheeu wheeu wheeu wheeu", at rate of c. 1 note every 2 seconds.
Habitat. Lower levels of evergreen forest (both *várzea* and *terra firme*) and deciduous forest, woodland, gallery forest, mature secondary growth and forest borders, especially near shaded streams, ravines and other watercourses; mainly *várzea* in Amazonia. Also mixed mangrove and palm swamps in E Venezuela (Delta Amacuro); into lower montane Atlantic Forest in SE Brazil. Mainly lowlands to 1400, but recorded as high as 2000 m in Perijá foothills (Venezuela); in Costa Rica, sea-level to 750-900 m on Pacific slope but below 400 m on Caribbean slope; sea-level to 800 m in SE Brazil; usually below 600 m, rarely to 900 m, in W Ecuador.
Food and Feeding. Arthropods, especially dragonflies (Odonata), lepidopterans, homopteran bugs, hymenopterans, and other large flying insects. Usually solitary; away from Amazonia, however, recorded as joining mixed-species flocks, e.g. in SE Brazil (race *swainsoni*) associating with furnariids (foliage-gleaners, fire-eyes). Forages in lower and middle levels of forest, often near watercourses; sits quietly on perch, upright and alert, with tail held downwards, while searching for prey, then sallies to snap prey in flight or from foliage without hovering. Larger prey often beaten against perch to remove wings before being swallowed.
Breeding. Mar-Jun in Mexico, Jan-May in W Ecuador and Jan or austral spring in SE Brazil. In display, performed during courtship and agonistic interspecific and intraspecific encounters, raises and fully spreads crest, rhythmically sways head from side to side along a 180-degree arc, while slowly opening and closing bill to reveal bright mouth-lining. Nest built by female, pensile, 0·6-2 m long, a loose and matted mass of rootlets, small epiphytes, moss, dead leaves and other plant fibres, side entrance to shallow open-fronted inner chamber near middle; frequently suspended from slender branch or drooping vine 2·4-6 m above ground, but often over forest stream; territory defended by male. Clutch 2 eggs; female incubates eggs and tends chicks; no other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Race *occidentalis* (often treated as a separate species) Vulnerable; also a restricted-range taxon, present in Tumbesian Region EBA. Race *swainsoni* (often treated as a separate species) Endangered. Generally widespread, but never common. Race *mexicanus* fairly common to uncommon in Mexico, but possibly extirpated from El Salvador owing to habitat loss; in Costa Rica, uncommon to fairly common in NE and on Pacific slope but rare in Caribbean lowlands. In Venezuela, uncommon to rare in S & E (nominate) and uncommon and local in NW (*fraterculus*). The two threatened races have both suffered severe and extensive habitat loss, fragmentation and degradation. W *occidentalis* is scarce to rare, occurs naturally at low densities, and appears to be on verge of extinction; total population within its 7500 km² range in W Ecuador and adjacent NW Peru estimated at 2500-10,000, and declining. It occurs in Río Palenque Science Centre, Jauneche Biological Reserve Station, Machalilla National Park, Cerro Blanco Forest Reserve, Manglares-Churute Ecological Reserve, and probably within Cordillera de Molleturo Protection Forest, all in Ecuador, and Tumbes National Reserve, in Peru. Habitat has suffered deforestation rates of 57% per decade from 1958 to 1988, and continuing rapid forest loss, coupled with degradation caused by grazing goats and cattle, may soon lead to disappearance of all unprotected forest habitat in the region; moreover, logging, livestock grazing and land clearance by settlers threaten important protected areas for this taxon; although it has been found to forage in degraded habitats, it is thought to depend on intact moist forest for breeding. A reforestation project within the partially forested Chongón-Colonche Protection Forest (776 km²) may benefit *occidentalis*; efforts to prevent further habitat degradation within protected areas and to survey areas of known and potential occurrence are necessary for its conservation. Similarly, race *swainsoni*, confined to the dwindling and severely fragmented forests of SE Brazil (possibly also an old record from Goiás), has an estimated total population of 2500-10,000 individuals and is also declining; it was always considered rare, and few recent records exist (e.g. in Paraná). Within its range of 3550 km², it occurs in Monte Pascoal, Itatiaia and Serra da Bocaína National Parks, Intervales State Park, Ubatuba Experimental Station, and Guaricana Forest Reserves (Guaratuba and Morretes); other important areas are near Estacão Vera Cruz (S Bahia), several sites in the Serra do Mar (São Paulo) and seven sites in Paraná. Habitat and population surveys and clarification of its taxonomic status would benefit the conservation of this taxon.
Bibliography. Anon. (1998a), Berg (2002b), Best & Kessler (1995), Clements & Shany (2001), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Graves (1990), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Lee Jones (2004), Monroe (1968), Munn (1985), Oren & Parker (1997), Parker & Carr (1992), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgely *et al.* (1998), Ridgway (1907), Sick (1993, 1997), Slud (1964), Stattersfield & Capper (2000), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Tobias *et al.* (1993), Tostain *et al.* (1992), Wege & Long (1995), Wetmore (1972), Whittingham (1994), Whittingham & Williams (2000), Williams & Tobias (1994), Zimmer (1939b).

Genus *CNIPODECTES*



P. L. Sclater & Salvin, 1873

203. **Brownish Twistwing**

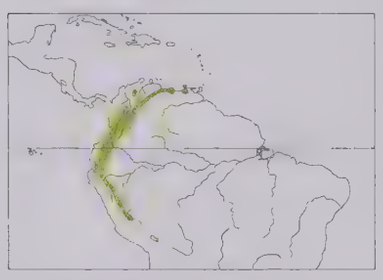
Cnipodectes subbrunneus

French: Platyrhynque brun **German**: Drehschwingentyrann **Spanish**: Mosquero Pardo
Other common names: Brownish Flycatcher

Taxonomy. *Cyclorhynchus subbrunneus* P. L. Sclater, 1860, Babahoyo, Los Ríos, Ecuador.
Affinities uncertain; toe structure suggests relationship to family Pipridae; a new species recently discovered in SE Peru appears to belong to this hitherto monospecific genus (see page 186). Races poorly differentiated; birds from E Panama and NW Colombia sometimes separated as race *panamensis*, but no visible differences in plumage from nominate. Two subspecies recognized.
Subspecies and Distribution.
C. s. subbrunneus (P. L. Sclater, 1860) - E Panama, W Colombia and W Ecuador.
C. s. minor P. L. Sclater, 1884 - W Amazon from Colombia and E Ecuador S to Peru, W Brazil and NW Bolivia.

Descriptive notes. 14-18 cm. Dull brown tyrannid with long and prominent rictal bristles. Male has dull brown head, buff loral spot; upperparts dull brown, wings darker or duskier, wing-coverts and tertials narrowly edged dull rufous-buff; uniquely modified outer primaries with stiffened and twisted shafts; rump and long tail more rufous or rufescent brown than back; throat pale brown or greyish-brown, becoming browner on breast, belly grey or yellowish dingy white, vent buff; iris brown to orange; bill broad, upper mandible black, lower mandible orange-yellow; legs black. Differs from similar Thrush-like Schiffornis (*Schiffornis turdina*) in having rufous edging on wings. Female is smaller than male, lacks distinctive primary morphology. Juvenile also has unmodified primaries. Race *minor* is similar to nominate, perhaps paler and tinged slightly more olive. Voice. Call a sharp, somewhat nasal whistle, "kuuuu-wit", usually doubled and occasionally tripled; song a distinctive and emphatic "kuheer", often repeated as "kuheer kuheer-quer", reminiscent of that of Blue-backed Manakin (*Chiroxiphia pareola*), often preceded by 1-2 loud bill-snaps. Audible mechanical "pr'r'r'r'r'" wing rattle in flight.
Habitat. Lower growth of humid and deciduous forest, secondary woodland; favours shady areas with many vines and tangles in understorey, areas above open dark forest floor, and near streams;

On following pages: 204. Flavescent Flycatcher (*Myiophobus flavicans*); 205. Orange-crested Flycatcher (*Myiophobus phoenicomitra*); 206. Unadorned Flycatcher (*Myiophobus inornatus*); 207. Roraiman Flycatcher (*Myiophobus roraimae*); 208. Handsome Flycatcher (*Myiophobus pulcher*); 209. Orange-banded Flycatcher (*Myiophobus lintoni*); 210. Ochraceous-breasted Flycatcher (*Myiophobus ochraceiventris*); 211. Olive-chested Flycatcher (*Myiophobus cryptoxanthus*); 212. Bran-coloured Flycatcher (*Myiophobus fasciatus*).



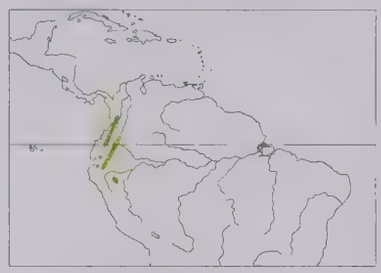
associated with bamboo in Bolivia, though not elsewhere. Seems to be confined to *terra firme* forest in E Ecuador. Mainly lowlands, ranging up Andean slopes to 1200 m (W Colombia); one record at 1900 m (Ecuador), possibly an error.
Food and Feeding. Little known. Insects. Usually solitary and often highly sedentary; rarely joins mixed flocks. Rather unsuspicious. Frequently slowly stretches one wing over back in a casual or leisurely motion.
Breeding In Colombia, Jan-Apr in W (N Antioquia, Chocó) and Jun in S (W Caquetá). Possibly occurs in scattered leks; use of uniquely modified primaries unknown, presumably serve a purpose in display. Nest (Barro Colorado I. in Panama) generally a pensile, cylindrical mass 1 m long, of dangling fibres, with side entrance, attached to aerial root 2 m above ground; similar to that of *Onychorynchus coronatus*. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Rare to uncommon in most of range; locally fairly common in Panama and E Ecuador. Appears to be fairly widespread. Numerous along Pipeline Road (Canal Zone), in Panama, and at Jauneche Biological Research Station and Manglares-Churute Ecological Reserve, both in Ecuador. Occurs also in Darién National Park, in Panama, Tinigua National Park, in Colombia, Jatun Sacha Biological Reserve, in Ecuador, and Jaú National Park, in Brazil. Numbers in W Ecuador have declined following deforestation, but this species may be capable of persisting in isolated forest fragments.
Bibliography. Anon. (1998a), Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Haffer (1975), Hilty & Brown (1986), López (1999b), Meyer de Schauensee (1982), Parker & Remsen (1987), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Traylor & Fitzpatrick (1982), Wetmore (1972), Zimmer (1939b).

Subfamily FLUVICOLINAE
Tribe CONTOPINI
Genus *MYIOPHOBUS* Reichenbach, 1850

204. **Flavescent Flycatcher**
Myiophobus flavicans

French: Moucherolle flavescent **Spanish**: Mosquero Amarillo
German: Gelbzügel-Schnäppertyrann

Taxonomy. *Myiobius flavicans* P. L. Sclater, 1861, Pallatanga, Ecuador.
Most closely allied with *M. phoenicomitra*, *M. inornatus* and *M. roraimae*. Five subspecies recognized.
Subspecies and Distribution.
M. f. perijanus Phelps, Sr & Phelps, Jr, 1957 - W Venezuela (Sierra de Perijá, also E slope of Tamá).
M. f. venezuelanus (Hellmayr, 1920) - N Venezuela (coastal range S to Andes of Táchira).
M. f. caripensis J. T. Zimmer & Phelps, Sr, 1954 - NE Venezuela.
M. f. flavicans (P. L. Sclater, 1861) - mountains of Colombia (all three ranges) S to E & W Ecuador and N Peru (N of R Marañón).
M. f. superciliosus (Taczanowski, 1875) - C Andes of Peru (S to Cuzco).



Descriptive notes. 12-12·7 cm; 10·2 g. Male nominate race has olive crown with semi-concealed yellow or orange coronal patch, prominent yellowish supraloral line and broken eyering; upperparts olive; wings and tail dusky, 2-3 cinnamon wingbars, lower one more prominent, remiges edged cinnamon, tertials edged buffy white, rectrices edged buffy olive; throat and underparts yellow, brightest on belly, breast flammulated with faint streaks of olive; iris dark; bill fairly broad, upper mandible black, lower mandible brownish or dusky flesh-coloured; legs black. Female lacks coronal patch. Juvenile is like female. Races vary in colours of coronal patch, supraloral stripe and eyering, breast colour and extent of flammulation, wing markings, and colour of lower mandible: *venezuelanus* is less flammulated below, has smaller and always yellow crown patch, flesh-coloured lower mandible; *caripensis* is similar to previous but yellower below, with less olive; *perijanus* is also similar but with all-dark bill; *superciliosus* has almost plain wings with one narrow cinnamon wingbar (on greater coverts), duller brown edges of remiges, all-black bill, yellower lores and eyering than nominate. Voice. Usually quiet. Call a sharp "tsink" or "chiyp"; infrequently heard song, perhaps given mainly at dawn, described as fast rhythmic series of 5-8 "kawhik" notes.
Habitat. Lower and middle strata of humid forest, forest borders, and bamboo tangles; 900-2700 m, mainly above 1500 m.
Food and Feeding. Insects, mostly hymenopterans, beetles (Coleoptera) and earwigs (Dermaptera), occasionally bugs (Hemiptera) and lepidopteran larvae. Forages alone or in groups of 2-3 birds, usually not with mixed-species flocks. Erect posture similar to that of *Empidonax* flycatchers. Forages by sallying short distances from low, dark perch to snatch prey from leaves, twigs, air or the ground.
Breeding. Nesting recorded in Feb in NE Venezuela (Cueva de los Guácharos) and SC Colombia (Huila); birds in breeding condition in Jun in N Venezuela (Perijá Mts), and in Colombia in Mar (SW Huila) and Oct (Boyacá); fledgling in Jul (W Nariño) and juvenile in Sept (Cundinamarca) in Colombia, and juveniles in Aug (NW) and Jan (NE) in Ecuador. Nest a cup of twigs and small vines, lined with feathers. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. In Venezuela, regular near Choroní Pass, in Henri Pittier National Park, and occurs on Cerro Negro, in Cueva del Guácharo National Park. Present also in Tambito Nature Reserve, in Colombia, and Guandera Biological Reserve, in Ecuador.
Bibliography. Chapman (1917c), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996).

205. **Orange-crested Flycatcher**
Myiophobus phoenicomitra

French: Moucherolle à cimier orange **Spanish**: Mosquero Crestinaranja
German: Olivrücken-Schnäppertyrann

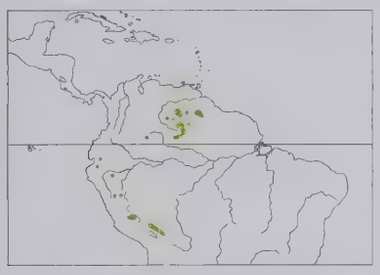
Taxonomy. *Myiobius phoenicomitra* Taczanowski and Berlepsch, 1885, [Hacienda] Mapoto, Tungurahua, Ecuador.
Most closely allied with *M. flavicans*, *M. inornatus* and *M. roraimae*. Two subspecies recognized.
Subspecies and Distribution.
M. p. litae (Hartert, 1900) - W slope of Andes in W Colombia and W Ecuador.
M. p. phoenicomitra (Taczanowski & Berlepsch, 1885) - E slope in E Ecuador and NE Peru.

Descriptive notes. 11·5-12 cm. Male has olive crown, semi-concealed orange-rufous, orange-red or golden-yellow coronal patch, sometimes a narrow yellow broken eyering; upperparts olive; wings blackish, 2-3 ochraceous wingbars, lower one more prominent, cinnamon-edged remiges, buffish-white edges of tertials; tail dusky, feathers edged buffy olive; throat and underparts yellow, brightest on belly, breast flammulated with faint streaks of olive; iris dark; bill fairly broad, upper mandible black, lower mandible flesh-coloured; legs black or dark grey. Female lacks coronal patch. Juvenile is similar to female, but browner above, cinnamon wingbars, buffy margins of tertials. Differs from *M. flavicans* in having generally darker upperparts with less buffy edging on tertials. Race *litae* is similar to nominate but smaller, slightly brighter yellow on belly, wider and deeper ochre wingbars. Voice. Call (NW Ecuador) a thin, weak, high-pitched "tsut, tseép-tsu".
Habitat. Lower growth of forest and forest borders, at 500-1550 m.
Food and Feeding. Insects, probably similar to those taken by *M. flavicans*. Solitary or in small groups of 2-3 individuals, usually not associated with mixed-species flocks. Erect posture similar to that of *Empidonax* flycatchers. Forages by sallying short distances from low perch, snatching prey from leaves, twigs, air or the ground.
Breeding. Birds in breeding condition in late Mar and mid-Jun in Colombia (upper Anchicayá Valley). No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Considered to be generally uncommon to fairly common, but local within its narrow elevational zone. Occurs in Podocarpus and Sangay National Parks, in Ecuador.
Bibliography. Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Strewe (2000b).

206. **Unadorned Flycatcher**
Myiophobus inornatus

French: Moucherolle simple **Spanish**: Mosquero Sencillo
German: Zimtflügel-Schnäppertyrann

Taxonomy. *Myiophobus inornatus* Carriker, 1932, Santo Domingo (Inca Mine), 6000 feet [c. 1830 m], Puno, Peru.
Most closely allied with *M. flavicans*, *M. phoenicomitra* and *M. roraimae*. Monotypic.
Distribution. E slope of Andes from SE Peru (S from Cuzco) S to N Bolivia (S to Cochabamba).



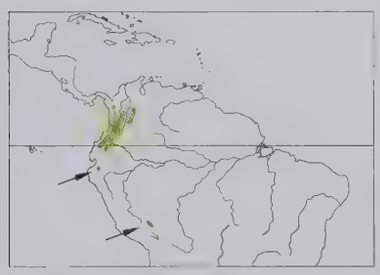
Descriptive notes. 11·5-12 cm. Male has olive crown with semi-concealed yellow or orange coronal patch, prominent yellowish supraloral line and broken eyering; upperparts olive; wings and tail dusky, two cinnamon-rufous wingbars, cinnamon-rufous edges of remiges, whitish-buff margins of tertials, rectrices edged buffy olive; throat yellowish-white, underparts pale yellow, breast flammulated with faint streaks of olive; birds from Bolivia (Cochabamba) generally more yellowish above and below; iris dark; bill fairly broad, upper mandible black, lower mandible flesh-coloured; legs black. Female probably lacks coronal patch. Juvenile undescribed. Distinguished from closely similar *M. flavicans* (of race *superciliosus*) mainly by browner upperparts. Voice. Call a high-pitched "zit" or "zib".
Habitat. Lower and middle levels of humid forest and forest borders, at 1000-2600 m.
Food and Feeding. Insects. Forages alone or in groups of 2-3 individuals, usually not with mixed-species flocks. Erect posture similar to that of *Empidonax* flycatchers. Makes short sallies from perch to snatch prey from leaves, twigs, air or the ground. Forages in more open areas and higher above ground than *M. flavicans*.
Breeding. Little known. Eggs recorded in Oct in Bolivia (La Paz) and Nov in Peru (Puno).
Movements. Probably resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Bolivian and Peruvian Lower Yungas EBA. Rare to uncommon, locally fairly common. Regularly seen along Manu road, in Peru. Forests within this species' range have been extensively converted for agricultural cultivation, especially cash crops such as coca and coffee. Several large protected areas have, however, been established, including Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, and Madidi National Park, in Bolivia.
Bibliography. Carriker (1935), Clements & Shany (2001), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey & Gómez (2003), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996).

207. Roraiman Flycatcher

Myiophobus roraimae

French: Moucherolle du Roraima **Spanish**: Mosquero del Roraima
German: Tepuischnäppertyrann

Taxonomy. *Myiobius roraimae* Salvin and Godman, 1883, Roraima, Venezuela.
Most closely allied with *M. flavicans*, *M. phoenicomitra* and *M. inornatus*. Three subspecies recognized.
Subspecies and Distribution.
M. r. roraimae (Salvin & Godman, 1883) - S & SE Venezuela and W Guyana.
M. r. sadiecoatsae Dickerman & Phelps, Jr, 1987 - Cerro de la Neblina, on border between S Venezuela and NW Brazil.
M. r. rufipennis Carriker, 1932 - very locally in E Colombia, Ecuador, SE Peru and NW Bolivia.



Descriptive notes. 13·5 cm; 12·8-13·6 g. Male has crown warm rufescent brown, tinged olive, auriculars more olive, semi-concealed orange-rufous coronal patch, narrow yellowish-white broken eyering; upperparts olive-brown, wings dusky or blackish, two broad rufous wingbars, rufous-edged remiges, buffier on edges of tertials; tail dusky brown with indistinct dark rufous margins; throat dull greyish-white, breast and flanks dull greyish-olive, belly pale yellow in centre; iris dark brown; bill fairly broad, upper mandible greyish-brown, lower mandible dull orange-yellow; legs grey. Female lacks coronal patch. Juvenile is similar to female. Races rather similar in plumage. Voice. Call (Ecuador) an explosive and buzzy series of sputtered "tschew" notes, rising and then descending; also a softer sharp "pit" or "tschit" note, sometimes doubled or trilled at end; occasionally a sputtered series of chattering between individuals, "jjttt-jjjttt-jjttt-tschit".
Habitat. Low and middle growth of humid forest on slopes of tepuis, and impoverished or sandy-soil forests of outlying Andean ridges. At 1300-1800 m on tepuis; on Cerro de la Neblina (race *sadiecoatsae*), 900-2000 m in Venezuela but down to 500 m on Brazilian side; 1100-1700 m in Andean region.
Food and Feeding. Diet consists of insects. Forages alone or in groups of up to three individuals, usually not with mixed-species flocks. Erect posture similar to that of *Empidonax* flycatchers. Forages by sallying short distances from low dark perch to snatch prey from leaves, twigs, air or the ground.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common in N of range; rare to uncommon and very local in Andes (race *rufipennis*), where only recently recorded for first time in Bolivia (two localities in La Paz). Occurs in several protected areas, including Canaíma National Park, in Venezuela.
Bibliography. Chapman (1931), Cory & Hellmayr (1927), Dickerman & Phelps (1987), Forrester (1993), Gilliard (1941), Hilty (2003), Hilty & Brown (1986), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Willard *et al.* (1991).

208. Handsome Flycatcher

Myiophobus pulcher

French: Moucherolle superbe **Spanish**: Mosquero Hermoso
German: Graukronen-Schnäppertyrann

Taxonomy. *Myiobius pulcher* P. L. Sclater, 1861, Quito, Ecuador.
Three subspecies recognized.
Subspecies and Distribution.
M. p. pulcher (P. L. Sclater, 1861) - W Colombia and NW Ecuador.
M. p. bellus (P. L. Sclater, 1862) - C & E Colombia and NE & SE Ecuador.
M. p. oblitus Bond, 1943 - SE Peru.

Descriptive notes. 9·5-11 cm. Male nominate race has crown olive grey, semi-concealed orange-rufous coronal patch, narrow white supraloral spot and broken eyering; nape olive-grey, rest of upperparts olive; wings dusky, two bold pale ochre (orange-buff) wingbars, pale ochre edges of secondaries (except at base) form dark patch alongside, outer webs of inner tertials edged whitish; tail relatively short, dusky; throat and breast dull ochre-yellow, belly pale yellow; iris dark; bill small, upper mandible black, lower mandible orange-yellow; legs grey. Female has coronal patch duller and reduced or absent. Juvenile undescribed. Race *bellus* is slightly larger than nominate, darker greyish-green above, deeper ochre wingbars, more distinct breastband of deeper ochre, slightly longer tail; *oblitus* resembles nominate but also slightly larger, with darker crown, buffy panel on basal portion of primaries. Voice. Song a clear sharp "tsi-tsi-tsi".
Habitat. Mostly middle and upper strata of humid forest, forest borders and secondary growth. Some variation in elevation among races; 1400-2600 m, rarely down to 800 m, in N (nominate) to 1500-3050 m in S (*oblitus*).
Food and Feeding. Insects. Usually in small group of 2-5 individuals, and accompanying mixed-species flocks of tanagers (Thraupidae) and other tyrannids in canopy. Forages by making short sallies to foliage or air.
Breeding. In breeding condition in Feb-Aug in Colombia. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Uncommon to common or fairly common in N (nominate and race *bellus*); rare and local in Peru (*oblitus*). Occurs in Tambito Nature Reserve, in Colombia, and Cotacachi-Cayapas, Cotopaxi, Sumaco-Galeras, Antisana and Llanganates National Parks and Cayambe-Coca Ecological Reserve, all in Ecuador. Poorly known species.
Bibliography. Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996).

209. Orange-banded Flycatcher

Myiophobus lintoni

French: Moucherolle de Linton **Spanish**: Mosquero de Linton
German: Orangeband-Schnäppertyrann

Taxonomy. *Myiophobus lintoni* Meyer de Schauensee, 1951, Cerro Imbana, 2600-2800 m, Loja, Ecuador.
Thought to be most closely related to *M. ochraceiventris*, both of which perhaps do not belong in this genus. Apparently replaces latter N of R Marañón (Peru). Monotypic.
Distribution. E slope of Andes in S Ecuador (Morona-Santiago, Azuay, Loja) and N Peru (Cerro Chinguela, in Piura).

Descriptive notes. 12·5 cm. Male is dark brownish-olive or greyish-olive above, darkest on crown, with semi-concealed yellow, orange or rufous coronal patch, inconspicuous narrow pale yellow eyering; wings and tail dusky, two broad cinnamon or ochraceous wingbars, outer remiges narrowly edged ochraceous, olive or white (inner remiges, tips of primaries and base of secondaries unmarked); yellow below, breast side washed olive; iris greyish-yellow to yellow; bill black, most of lower mandible dull orange; legs greyish. Female has coronal patch dull dark brown and reduced (or lacking), may also be paler yellow below. Juvenile lacks coronal patch, has deeper rufous-buff wingbars, paler underparts, yellow base of upper mandible and entire lower mandible. Voice. Calls include sharp "chip" and "chep" or "peeyk" notes, repeated while foraging; dawn song a series of "tsin" notes.
Habitat. Middle and, rarely, upper levels of montane forest, cloudforest and elfin forest, and second growth at forest borders and landslides; 2250-3200 m.
Food and Feeding. Insects; possibly also fruit. Forages alone or in groups of 2-6 individuals, at times actively, often with mixed flocks, including tanagers (Thraupidae). Erect posture similar to that of *Empidonax* flycatchers. Uses short sallies to glean insects from upper leaf surfaces, as well as upward sallies, and hover-gleaning, perch-gleaning and hanging manoeuvres; often perches on top of large leaves.
Breeding. Juvenile and immature reported in Jun. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Southern Central Andes EBA. Rare to fairly common, but local within tiny range. In Ecuador, relatively numerous in Tapichalaca Reserve (above Valladolid, in Zamora-Chinchipe) and in Cordillera de Cordoncillo (S of Saraguro, in Loja), and occurs also in Podocarpus National Park (Cajanuma sector). Habitat loss, and forest degradation caused by grazing livestock, pose a major risk to this species. Because of its very limited range and continuing rapid habitat destruction, it may even merit conservation status of Vulnerable.
Bibliography. Bloch *et al.* (1991), Clements & Shany (2001), Collar *et al.* (1994), Cracraft (1985), Fjeldså & Krabbe (1990), Jácome (2002b), Meyer de Schauensee (1982), Parker *et al.* (1985), Rasmussen *et al.* (1996), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996).

210. Ochraceous-breasted Flycatcher

Myiophobus ochraceiventris

French: Moucherolle à poitrine ocre **Spanish**: Mosquero Pechiocre
German: Ockerhals-Schnäppertyrann

Taxonomy. *Mitrephorus ochraceiventris* Cabanis, 1873, Marayniоc, Junín, Peru.
Thought to be most closely related to *M. lintoni*, both of which perhaps do not belong in this genus. Apparently replaced by latter N of R Marañón, in Peru. Monotypic.
Distribution. E slope of Andes from N Peru (S & E of R Marañón) S to NW Bolivia.

Descriptive notes. 12-14 cm; 10-11 g. Male has dark brownish-olive crown, semi-concealed yellow to reddish-orange coronal patch (becoming redder S of C Peru), dusky lores, ochre supraloral patch and crescent above eye, thin buffy crescent below eye; ear-coverts, nape and upperparts brownish-olive, wings and tail dusky, two prominent buff-whitish wingbars, margins of secondaries yellowish, margins of tertials white; chin yellowish, throat and breast orange-ochre (colour extending under ear-coverts), belly yellow; iris dark; bill all black; legs black. Female has coronal patch duller reddish-chestnut. Juvenile usually lacks coronal patch. Voice. Call (Peru) a sharp and emphatic "tschew-it", sometimes followed by slightly sweeter "tse-weeuuu"; also a hard but soft "theeuuk"; in excitement a series of soft but sharp "pstttpsst", sometimes followed by thin descending trill, which in turn occasionally followed by series of harsh scolding "scwee-scwee" or "schee-schee-schee" notes.
Habitat. Montane forest, cloudforest and elfin forest and humid thickets, near timber-line; 2800-3500 m, locally down to 2200 m.
Food and Feeding. Insects; some fruit also eaten. Forages alone or in groups of 3-5 individuals, often with mixed-species flocks of tanagers (Thraupidae). Erect posture similar to that of *Empidonax* flycatchers. Forages in middle and upper strata of forest, using short sally, hover-glean, perch-glean and hanging manoeuvres; often perches on top of large leaves.
Breeding. Juvenile reported in Mar in Peru. No other information.
Movements. Probably resident.

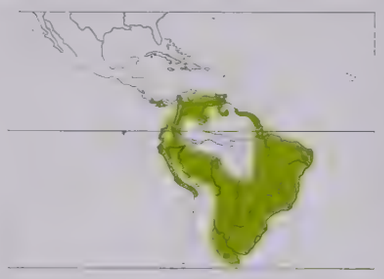
Status and Conservation. Not globally threatened. Locally fairly common to common. In Peru, regularly observed in Río Abiseo National Park and in the Machu Picchu Historical Sanctuary (Sayacmarca-Phuyupatamarca Inca Trail), and from Shintuya-Paurcatambo (Manu) road, in Cuzco. Also regular in Chusipata area of Yungas in La Paz, in Bolivia.
Bibliography. Chapman (1921), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Remsen (1984, 1985), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001).

211. Olive-chested Flycatcher

Myiophobus cryptoxanthus

French: Moucherolle à poitrine olive **Spanish**: Mosquero Pechioliva
German: Grauflecken-Schnäppertyrann

Taxonomy. *Myiobius cryptoxanthus* P. L. Sclater, 1861, Zamora, Zamora-Chinchipe, Ecuador.
Monotypic.
Distribution. Base of E Andes in E Ecuador (Sucumbíos S to Zamora-Chinchipe) and NE Peru (San Martín).



Descriptive notes. 12 cm. Has dull olive-brown crown, semi-concealed yellow coronal patch, dark lores, whitish supraloral line and thin broken eyering; head side, nape and upperparts dark olive, wings and tail dusky, two broad pale whitish-buff wingbars; throat dirty white, breast with band of broad greyish-olive streaks, blurry streaking on flanks, pale yellow belly and vent; iris dark; bill all black; legs black. Sexes alike. Juvenile undescribed. Voice. Calls include "weee d'd'd'd'd'd'd"; dawn song a repeated series of "chwee" notes. Similar to voice of *M. fasciatus*.
Habitat. Shrubby clearings, pastures, secondary woodland and forest borders in foothills and E Andean slopes; mostly 300-1100 m, occasionally as high as 1800 m.
Food and Feeding. Insects, including beetles (Coleoptera), ants and small wasps (Hymenoptera), flies (Diptera); some small berries probably also taken. Forages alone or in pairs, not with mixed-species flocks, and usually low, close to ground. Uses aerial sallies and perch-glean manoeuvres to capture prey from air or leaves.
Breeding. No information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Restricted-range species; present in Upper Amazon-Napo Lowlands EBA. Uncommon to locally fairly common in Ecuador, rare in Peru; range possibly extends N into adjacent S Colombia. This species benefits from forest clearance, and is possibly increasing in E Ecuador; now numerous in Zumba region and along Loreto road N of Archidona, but becomes scarcer towards E lowlands. Fairly common in Serranías Cofán, Sucumbíos, and occurs also in Jatun Sacha Biological Station and Podocarpus National Park, all in Ecuador.
Bibliography. Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Hornbuckle (1999), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Zimmer (1939b).

212. Bran-coloured Flycatcher

Myiophobus fasciatus

French: Moucherolle fascié **German**: Rostschnäppertyrann **Spanish**: Mosquero Estriado
Other common names: Rufescent/Lima Flycatcher (*rufescens*)

Taxonomy. *Muscicapa fasciata* Statius Muller, 1776, Cayenne.
Race *rufescens* distinctive, possibly a separate species. Seven subspecies recognized.
Subspecies and Distribution.
M. f. furfurosus (Thayer & Bangs, 1905) - SW Costa Rica (Téraba Valley) and W Panama (including Pearl Is).
M. f. fasciatus (Statius Muller, 1776) - Venezuela, Trinidad, the Guianas, N Brazil (Amapá), Colombia (except SW) and E Ecuador.
M. f. crypterythrus (P. L. Sclater, 1861) - SW Colombia, W Ecuador and NW & N Peru.
M. f. rufescens (Salvadori, 1864) - W Peru and extreme N Chile.
M. f. saturatus (Berlepsch & Stolzmann, 1906) - E Peru.
M. f. auriceps (Gould, 1839) - SE Peru, W Brazil, N & E Bolivia, N Argentina and W Paraguay.
M. f. flammiceps (Temminck, 1822) - E Brazil and E Paraguay S to NE Argentina and Uruguay.

Descriptive notes. 12-12·7 cm; 9·5-10·5 g. Male nominate race has reddish-brown crown, semi-concealed yellow to orange-rufous coronal patch, short yellowish-white supraloral line and thin eyering, brown lores; head side, nape and upperparts reddish-brown; wings dusky or dark brown, two broad and prominent buff-white wingbars, buff-white edges of tertials, margins of secondaries dark basally, then narrowly edged buff (sometimes forming light panel in wing); tail dark brown; throat and underparts dull white, short fine greyish-brown streaks across breast and flanks, centre of belly sometimes tinged yellow; iris dark; upper mandible black, lower mandible dark with orange-yellow basally; legs black. Female is less heavily streaked below, has coronal patch much reduced or absent. Juvenile lacks coronal patch, is brighter above, wingbars more rufous. Races vary in plumage and size, slightly larger in S: *saturatus* is duller than nominate, brown of upperparts lacking rufous tinge, belly deeper yellow; *auriceps* is very like nominate, but darker brown above, darker brown streaking on breast, white belly; *flammiceps* is larger, warmer brown above, white belly; *crypterythrus* is more distinctive, crown patch rufous, upperparts brownish-grey, heavier streaking on breast, white belly; *furfurosus* has most reddish-brown upperparts of all, rufous-white wingbars, yellower on belly, orange-yellow lower mandible; *rufescens* is most distinctive, brown above, ochre to rufous wingbars, uniform orange-rufous and unstreaked below. Voice. Call described as "chlep", "jewleh", muffled "squek" or low "wheesp" or "wheeh". Dawn song a series of low husky whistles in a repeated phrase e.g. as "tep, chew-e", "weé, wu-du", "djili-dju" or "jili-juh", middle note lowest after slight pause; daytime song a rattled trill, "whee-yee-yee-yee-yee-yee" or "wee'he'he'he'e".
Habitat. Lower to middle strata of dry forest, forest edge, brushy savanna, hedgerows and pastures, riparian thickets in arid areas; also successional vegetation along rivers and on river islands. *llanos* in E Colombia and Venezuela, *capoeira* in Brazil. Also bamboo at 500-1000 m in SE Peru during austral winter. Sea-level to 1500 m; also higher, to 2650 m in Bolivia (*auriceps*) and to 2600 m in E Andes of Colombia (nominate); 900-1200 m in Costa Rica.
Food and Feeding. Insects, including beetles (Coleoptera), ants and small wasps (Hymenoptera) and flies (Diptera); some small berries also included in diet. Forages alone or in pairs, not with mixed-species flocks. Perches upright, often twitching wings, occasionally also tail. Uses aerial sallies and perch-glean manoeuvres to capture prey from air or leaves, usually low down, close to ground.
Breeding. Apr-Jun in Costa Rica, Mar-Aug (once Oct) in Trinidad and Oct-Jan/Feb in Argentina. Nest a deep and well-constructed cup, internal diameter c. 4 cm, depth c. 4 cm, usually of grass, thin stems, vines, rootlets, with green moss on outside, usually bound by spiderwebs, saddled in fork of small tree or shrub 1·2-3·6 m above ground. Clutch 2 eggs, sometimes 1; incubation by female, period usually 17 days; chicks fed by both parents, fledging period 15-17 days. Nest sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Mostly resident; S populations migratory. Those breeding S of about Paraguay and SE Brazil (Rio Grande do Sul) leave breeding grounds during austral winter; increase in numbers also recorded in SE Peru during austral winter.
Status and Conservation. Not globally threatened. Fairly common to common through much of its range, and the most widespread of genus; somewhat more local in Costa Rica, the Guianas and E Ecuador. Occurs in many national parks and other protected areas. Benefits from habitat conversion; appears to thrive in shrubby successional vegetation that follows deforestation. Race *rufescens*, possibly a separate species, is confined to relatively small range on Pacific slopes in W Peru and N Chile; seems less numerous and more local, but does occur in Northwest Biosphere Peru Reserve, in Peru.
Bibliography. Anon. Genus *MYIOBIUS* Darwin, 1839

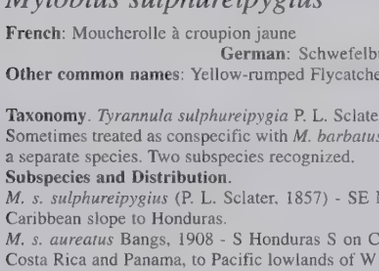
213. Tawny-breasted Flycatcher

Myiobius villosus

French: Moucherolle hérissé **German**: Gebirgsborstentyrann **Spanish**: Moscareta Vellosa

Taxonomy. *Myiobius villosus* P. L. Sclater, 1860, Nanegal, Pichincha, Ecuador.
Four subspecies recognized.
Subspecies and Distribution.
M. v. villosus P. L. Sclater, 1860 - locally in E Panama (Cerro Taracuna), W Colombia and NW Ecuador.
M. v. schaeferi Aveledo & Pons, 1952 - locally in NE Colombia and W Venezuela.
M. v. clarus J. T. Zimmer, 1939 - E Ecuador and E Peru.
M. v. peruvianus Todd, 1922 - SE Peru and NW Bolivia.



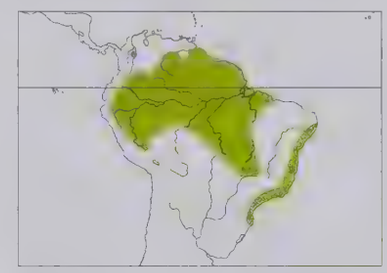
Descriptive notes. 14 cm; 13 g. Large eyes, prominent long rictal bristles. Male nominate race has crown, nape, and upperparts dark brownish-olive, semi-concealed yellow coronal patch, paler supraloral area, pale eyering broader to rear, greyer on face; rump sulphur-yellow, uppertail-coverts black; wings dark with olive-brown feather edges; tail long, rounded, black; throat dirty white, underparts mostly ochre to tawny-brown, central belly dull yellow; iris dark; bill broad, upper mandible grey to black, lower mandible flesh-coloured with dusky tip; legs grey. Distinguished from *M. sulphureipygius* by larger size, darker coloration, especially on underparts. Female is similar to male, but coronal patch cinnamon-rufous or absent. Races differ subtly in plumage, mainly in coloration of upperparts and underparts: *schaeferi* resembles nominate but has stronger indication of breastband; *peruvianus* has more distinct band on breast, more extensive yellow below; *clarus* differs from previous in generally greener upperparts. Voice. Generally quiet; sometimes a sharp "espít" call note, similar to that of *M. sulphureipygius*.
Habitat. Lower and middle levels of montane forest, near streams. Occurs at 900-2100 m, locally down to 600 m; mainly at higher elevations than its congeners in Andes.
Food and Feeding. Arthropods, notably hymenopterans, coleopterans, homopteran bugs, and arachnids. Analysis of 77 prey items taken from stomachs in SE Peru gave: Coleoptera (44%); Hymenoptera (bees and wasps 25%, ants 21%); and Homoptera (planthoppers 5%, cicadas 5%). Singly or in pairs; regularly accompanies mixed-species flocks. Actively forages at low to middle levels, perhaps higher than *M. barbatus*; often fans tail, reminiscent of Old World fantails (*Rhipidura*), and droops wings to expose yellow rump; often pivots on perch, and frequently changes perches. Uses flush-and-chase strategy similar to that of *Myioborus*, pursuing flushed prey in short, acrobatic, aerial sallies.
Breeding. Not well known; probably similar to that of congeners.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Rare to locally common; particularly numerous at El Placer (Esmeraldas), in NW Ecuador. Occurs in Tambito Nature Reserve, in Colombia, Machalilla National Park, in Ecuador, and Madidi National Park and Pilón Lajas Biosphere Reserve, both in Bolivia.
Bibliography. Anon. (1998a), Aveledo & Pons (1952), Becker *et al.* (2000), Begazo (1995), Butler (1979), Chapman (1917c), Cory & Hellmayr (1927), Cracraft (1985), Delgado (1985), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Strewe (2000b), Wetmore (1972), Zimmer (1930, 1939a).

214. Sulphur-rumped Flycatcher

Myiobius sulphureipygius

French: Moucherolle à croupion jaune **Spanish**: Moscareta Culiamarilla
German: Schwefelbürzel-Borstentyrann
Other common names: Yellow-rumped Flycatcher (*aureatus*)

Taxonomy. *Tyrannula sulphureipygia* P. L. Sclater, 1857, Córdoba, Veracruz, Mexico.
Sometimes treated as conspecific with *M. barbatus*. Race *aureatus* thought by some to be possibly a separate species. Two subspecies recognized.
Subspecies and Distribution.
M. s. sulphureipygius (P. L. Sclater, 1857) - SE Mexico (from S Veracruz and N Oaxaca) S on Caribbean slope to Honduras.
M. s. aureatus Bangs, 1908 - S Honduras S on Caribbean slope, and locally on Pacific slope in Costa Rica and Panama, to Pacific lowlands of W Colombia and W Ecuador.



Descriptive notes. 12-13·5 cm; 12 g. Large eyes, prominent long rictal bristles. Nominate race has crown, nape and back dark olive, semi-concealed yellow coronal patch, paler loral region and cheek contrast with pale buffy-white eyering, latter broader to rear, and dark auricular mark; rump sulphur-yellow, uppertail-coverts black; wings dark with brown-olive feather edges; tail long, rounded, black; throat yellowish to buffy white, chest and sides ochraceous tawny, belly pale yellow; iris dark; bill broad, upper mandible grey to black, lower mandible flesh-coloured with dusky tip; legs grey. Female has yellow coronal patch reduced or absent. Juvenile also lacks yellow coronal patch, is browner above, paler below, sooty fringes of breast feathers giving smudgy look. Race *aureatus* differs from nominate in having brighter tawny breast and flanks. Voice. A "psik" call, often while foraging. Song a clear series of 4-6 "tschew" notes or "tseuu tseuu tseuu tseer tseer", quiet, rising and then falling, reminiscent of Dot-winged Antwren (*Microrhopias quixensis*). Dawn song a rapid repeated "chu wee-da-wiit" or "chu wee-da-ti-wit".
Habitat. Shady understorey and low to middle levels of humid forest, *terra firme* forest, gallery forest and old second growth. Typically, sea-level to 1000 m; 800-1200 m in Costa Rica.
Food and Feeding. Arthropods; diet probably similar to that of *M. villosus*. Singly or in pairs; often accompanies mixed-species flocks. Active forager, often fanning tail and drooping wings to expose yellow rump; also frequently flicks wings sideways, pivots on perch, and changes perches. Pursues flushed prey in short acrobatic aerial sallies; actively forages with *Myioborus*-like antics at low to middle levels, using a flush-and-chase strategy. Regularly with mixed flocks, including those following army ants, and often captures prey flushed by other birds.
Breeding. Mar-Jun in Costa Rica. Female constructs a messy, bell-shaped or pyriform nest of fine brown plant fibres, often suspended over stream from vine or twig 1-14 m up in open understorey; entrance low on side of nest, often covered by a "hood", bird often flies upwards to enter. Clutch 2 eggs; no information on incubation and fledging periods; chicks tended by female.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common, and widely distributed. Quite local in certain areas owing to deforestation (e.g. Chiriquí, in Panama). Occurs in several national parks and other protected areas throughout its range, including Columbia River Forest Reserve and Lamanai Archaeological Reserve, in Belize, Laguna del Tigre National Park, in Guatemala, and Rancho Naturalista, Tarcol Lodge and Río Negro Jaguar Reserve, all in Costa Rica.
Bibliography. Anon. (1998a), Brodkorb (1943), Cory & Hellmayr (1927), Dearborn (1907), Greenberg (1992), Haffer (1974, 1975), Hilty (2003), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Land (1970), Lee Jones (2004), Lowery & Dalquest (1951), Monroe (1968), Paynter (1955, 1957), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Salaman (1994), Skutch (1960), Slud (1960, 1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1943, 1944, 1972), Williams & Tobias (1994), Winker *et al.* (1999).

215. Whiskered Flycatcher

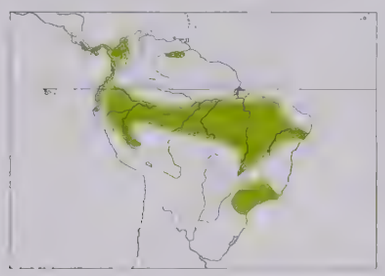
Myiobius barbatus

French: Moucherolle barbichon **Spanish**: Moscareta Barbada
German: Gelbbauch-Borstentyrann
Other common names: Bearded Flycatcher

Taxonomy. *Muscicapa barbata* J. F. Gmelin, 1789, Cayenne.
Sometimes treated as conspecific with *M. sulphureipygius*. Race *mastacalis* possibly a separate species. Five subspecies recognized.
Subspecies and Distribution.
M. b. semiflavus Todd, 1919 - NC Colombia.
M. b. barbatus (J. F. Gmelin, 1789) - SE Colombia, E, S & SE Venezuela and the Guianas S to N Peru and NC Brazil.
M. b. amazonicus Todd, 1925 - E Peru and C Brazil.
M. b. insignis J. T. Zimmer, 1939 - NE Brazil.
M. b. mastacalis (Wied, 1821) - SE Brazil.

Descriptive notes. 12·5-12·7 cm; 11 g. Large eyes, prominent long rictal bristles. Nominate race has crown, nape and back olive-green, semi-concealed yellow coronal patch, paler loral region, yellowish-white eyering broadening to rear, greyer face; rump sulphur-yellow, uppertail-coverts black; wings dusky brown, slightly paler olive-brown margins of remiges; tail long, rounded, black; throat dirty white, chest grey with olive or brown tinge, sides often tinged ochre (variable), belly pale yellow; iris dark; bill broad, upper mandible grey to black, lower mandible flesh-coloured with dusky tip; legs grey. Sexes similar, but female has coronal patch reduced or lacking. Juvenile resembles female. Races differ slightly in breast colour: *mastacalis* is brightest and most distinct, with breastband tinged tawny-ochre; *insignis* is dullest, almost beige-tinged grey-olive across chest; *amazonicus* is slightly more greyish-olive across chest than previous; *semiflavus* resembles nominate but duller. Voice. Generally silent; sometimes a high sharp "tsip" or "psik" call note.
Habitat. Shady understorey and low to middle levels of humid forest, *terra firme* forest, gallery forest and old second growth, often near streams. Typically, sea-level to 1000 m; mostly below 600 m but locally to 1300 m in Ecuador. Replaced by *M. atricaudus* in drier forest, and by *M. villosus* at higher elevations.
Food and Feeding. Arthropods. Singly or in pairs; regularly accompanies mixed-species flocks that include thamnophilids (e.g. *Myrmotherula* antwrens, antshrikes), furnariids and others. Actively forages at low to middle levels; perches horizontally, often fans tail in manner reminiscent of Old World fantails (*Rhipidura*), droops wings to expose yellow rump, pivots on perch, and frequently changes perches. Uses flush-and-chase strategy, pursuing flushed prey in short acrobatic aerial sallies.
Breeding. Builds suspended pyriform nest with a roof or hood of overhanging twigs, and a side entrance; 2-10 m above ground. No further information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in many national parks and other protected areas throughout its range, e.g. Tinigua National Park, in Colombia, Manu National Park and Biosphere Reserve, in Peru, and at least three national parks and many other reserves in Brazil. Much of this species' habitat remains in relatively pristine condition, and it seems unlikely to be at any potential risk.
Bibliography. Anon. (1998a), Bangs & Penard (1918), Chapman (1931), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Friedmann (1948), Gilliard (1941), Haffer (1974), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (1997, 2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Payne (1984), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001),

On following pages: 216. Black-tailed Flycatcher (*Myiobius atricaudus*); 217. Ruddy-tailed Flycatcher (*Terenotriccus erythrurus*); 218. Cinnamon Tyrant (*Neopipo cinnamomea*); 219. Cinnamon Flycatcher (*Pyrrhomyias cinnamomeus*); 220. Cliff Flycatcher (*Hirundinea ferruginea*).



Sick (1993, 1997), Skutch (1981), Snethlage (1935), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer (1930, 1939a).

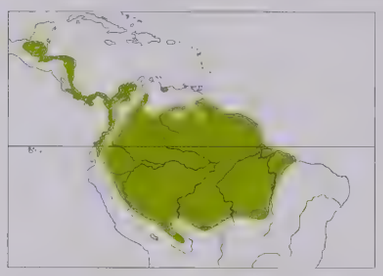
216. **Black-tailed Flycatcher**

Myiobius atricaudus

French: Moucherolle à queue noire **Spanish**: Moscareta Colinegra
German: Schwarzschwanz-Borstentyrann

Taxonomy. *Myiobius atricaudus* Lawrence, 1863, Isthmus of Panama.
Race *portovelae* sometimes lumped with nominate because of similarities in plumage and poorly defined geographical boundaries between the two. Seven subspecies recognized.
Subspecies and Distribution.
M. a. atricaudus Lawrence, 1863 - SW Costa Rica S to W Colombia.
M. a. modestus Todd, 1912 - locally in C & E Venezuela (N Bolívar).
M. a. portovelae Chapman, 1924 - W Ecuador and NW Peru.
M. a. adjacens J. T. Zimmer, 1939 - S Colombia, E Ecuador, E Peru, and W Brazil S of Amazon.
M a. connectens J. T. Zimmer, 1939 - NC & NE Brazil S of Amazon
M. a. snethlagei Hellmayr, 1927 - coastal NE Brazil.
M. a. ridgwayi Berlepsch, 1888 - SE Brazil.

Descriptive notes. 12-12·7 cm; 10 g. Large eyes, prominent long rictal bristles. Nominate race has crown, nape and back dark olive-green, semi-concealed yellow coronal patch, paler loral region, pale eyering broader to rear, greyer face; rump sulphur-yellow, uppertail-coverts black; wings dark with olive feather edges; tail long, rounded, black; throat dirty white, chestband dull tawny-buff or olive-buff, belly dull yellow; iris dark; bill broad, upper mandible grey to black, lower mandible dark flesh-coloured with dusky tip; legs grey. Sexes similar, but female has coronal patch smaller than male's. Immature resembles adult, but lacks yellow coronal patch. Races vary mainly in warmth of olive tone on chest, degree and intensity of yellow on belly, and coloration of rump: *portovelae* has breastband much warmer ochre-olive (warmest of "banded" races), belly brighter yellow; *modestus* has breastband slightly more ochre-tinged than nominate but still somewhat dull, not nearly so warm as previous; *adjacens* is in general somewhat paler than nominate, rump whiter, chest more buffy; *connectens* is rather dull, chest brownish-buff, rump whitish; *snethlagei* is distinctive, rump brighter yellow with slight orange-buff tinge, solid yellow below, slightly brighter on throat and breast (but no breastband effect); *ridgwayi* is also distinctive, similar in pattern to previous, but rump and underparts orange-buff, slightly richer on breast (no breastband), slightly browner on upperparts. Voice. Generally quiet; call a soft wiry "tsit" or "wit", weaker than that of *M. sulphureipygius*; song a sweet "cheer-cheer-cheer".
Habitat. Lower growth of dry to humid forest, lighter woodland, shrubby second growth, and forest borders, near water. In Amazonia found in *várzea* forest, and replaced by *M. barbatus* in *terra firme* forest; in Costa Rica, inhabits gallery woodland where *M. sulphureipygius* is absent. Sea-level to 1000 m in most of range; below 200 m in Venezuela; to 1400 m in arid valleys of W Colombia.
Food and Feeding. Arthropods. Singly or in pairs; regularly accompanies mixed-species flocks. Actively forages at low to middle levels; fans tail and droops wings, although not so frequently as do some other members of genus; frequently pivots on perch and changes perches. Uses flush-and-chase strategy, pursuing flushed prey in short aerial sallies, or sally-gleans insects from leaves. Often somewhat less active and acrobatic than *M. barbatus*.
Breeding. Apr in Costa Rica and Jun-Jul in Panama. Female constructs a messy bell-shaped or pyriform nest of fine brown plant fibres, suspended 0·4-3 m above ground, especially above stream or shore; side entrance low down, covered by "hood", bird often flying upwards to enter. Clutch 2 eggs; no information on incubation and fledging periods; chicks tended by female.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in Tarcol Lodge, in Costa Rica, Tambito Nature Reserve, in Colombia, Cerro Blanco Forest Reserve, Machalilla National Park, Manglares-Churute Ecological Reserve and Río Palenque Science Centre, in Ecuador, Northwest Peru Biosphere Reserve, in Peru, and Itatiaia National Park, Mata dos Godoy State Park (Paraná) and Cerros de Mata Estrela Private Reserve (Rio Grande do Norte), in Brazil. Numbers in In W Ecuador reduced because of habitat destruction (as in other disturbed areas), but much of the species' habitat within its relatively large range is still in reasonably pristine condition.
Bibliography. Anon. (1998a), Cory & Hellmayr (1927), Cracraft (1985), Haffer (1975), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Pacheco *et al.* (1996), Payne (1984), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Salaman (1994), Schubart *et al.* (1965), Sick (1993, 1997), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972), Williams & Tobias (1994), Zimmer (1930, 1939a).



Genus *TERENOTRICCUS* Ridgway, 1905

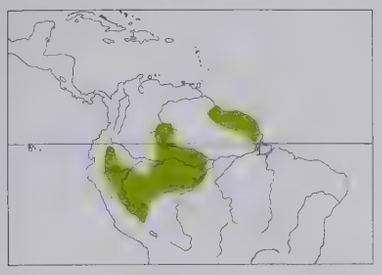
217. **Ruddy-tailed Flycatcher**

Terenotriccus erythrurus

French: Moucherolle rougequeue **German**: Rotschwanztyrann **Spanish**: Mosquerito Colirrojo

Taxonomy. *M[yiobius] erythrurus* Cabanis, 1847, Cayenne.
Genus sometimes merged with *Myiobius*, with which thought to form a monophyletic clade. Validity of most races considered doubtful, and *signatus*, *purusianus* and *amazonus* perhaps better merged with *brunneifrons*; further work required to resolve internal taxonomy. Eight subspecies currently recognized.
Subspecies and Distribution.
T. e. fulvigularis (Salvin & Godman, 1889) - SE Mexico (from Tabasco and S Campeche), N Guatemala and Belize S to Panama, N & W Colombia and NW Ecuador, and locally in N Venezuela.
T. e. venezuelensis J. T. Zimmer, 1939 - SE Venezuela (Amazonas, S Bolívar) and immediately adjacent E Colombia (R Guainía) and extreme NW Brazil (upper R Negro).
T. e. erythrurus (Cabanis, 1847) - E Venezuela (E Bolívar), the Guianas and NE Brazil (R Negro E to Amapá).
T. e. signatus J. T. Zimmer, 1939 - E Colombia S to E Ecuador, E Peru (N of R Marañón) and locally NW Brazil (NW Amazonas S to R Solimões).
T. e. brunneifrons Hellmayr, 1927 -E Peru (S of R Marañón), adjacent SW Brazil and NW & W Bolivia.
T. e. purusianus (Parkes & Panza, 1993) - middle R Purús region of W Brazil.
T. e. amazonus J. T. Zimmer, 1939 - C Brazil S of Amazon (R Purús E to R Tapajós, S along R Madeira to region of mouth of R Jiparaná).
T. e. hellmayri (E. Snethlage, 1907) - NE Brazil along lower R Tocantins E to Maranhão.

Descriptive notes. 9-10·3 cm; male 7 g, female 6 g. Small flycatcher, rufous overall, with unusually large black eyes, short bill, peaked crown, prominent rictal bristles. Nominate race has crown and nape olive-grey, forehead tinged ochre, faint narrow white eyering and supraloral area, buffy cheek; back grey, tinged olive or brown, rump bright cinnamon; dusky wing-coverts and remiges broadly edged cinnamon-rufous, tail rufous; throat greyish, underparts uniform cinnamon-buff, breast with olive flammulations or tinge; iris black; upper mandible black, lower mandible pale flesh-coloured with dusky tip; legs yellowish-orange to pale brown. Sexes alike. Juvenile is brighter overall, tail darker with dusky tip, darker breast tinged olive. Races similar, varying mostly in coloration of underparts, back and crown, only nominate with distinct olive on breast: *fulvigularis* is perhaps brightest orange-buff below; *hellmayri* has whitish throat contrasting sharply with slightly brighter orange-rufous breast; *venezuelensis* is perhaps paler grey-olive on crown and back; *brunneifrons*, *signatus*, *purusianus* and *amazonus* have throat whitish to buff. Voice. Often quiet but does vocalize throughout day. Call, often repeated at dawn, a high, thin and rather faint "teeu-téép", second note much higher, may recall *Corythopis*, Grey-bellied Spinetail (*Synallaxis cinarescens*) or a hummingbird (Trochilidae). Song insect-like though slightly more musical, a relatively soft, clear and penetrating series of 6-7 high, thin whistles, first 2-3 louder, then accelerating and descending in pitch, "keeek, keeek, eek-eek-eek-eek-eek"; occasionally slowly rising and then falling, "wi wi wi keek...keek, keek keek keek keek". Urgent "pee peew peew peew" in interactions.
Habitat. Lower and middle levels of *terra firme*, *várzea* and secondary forest; also recorded in coconut groves in Brazil. Sea-level to 1200 m.
Food and Feeding. Small insects, especially homopteran bugs. Analysis of 47 prey items taken from stomachs in SE Peru gave: Homoptera (planthoppers 96%); Coleoptera (2%); and Hymenoptera (ants 2%). Usually forages alone, but occasionally joins mixed-species flocks. Searches from perch, in vertical posture, often flicks wings quickly over back; abruptly darts in pursuit of prey, using aerial sallies or hover-gleaning manoeuvres, often continuing to new perch. Frequently vocalizes while foraging.
Breeding. Mar-May in Costa Rica and Feb-Aug in NW Colombia. Nest built by female, an elongated pear-shaped pouch, "visor" protecting side entrance near bottom, generally composed of dark fibres and dead leaf fragments, suspended from vine or twig 1·5-2 m up. Clutch 2 eggs; no information on incubation and fledging periods; chicks cared for by female.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally common. Occurs in many national parks and other protected areas within its relatively large range. Numbers reduced wherever habitat destruction has taken place, but much of habitat occupied by this species remains in fairly pristine condition.
Bibliography. Anon. (1998a), Begazo (1995), Ceballos & Valdelamar (2000), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Lee Jones (2004), Mobley & Prum (1995), Oren & Parker (1997), Parkes & Panza (1993), Payne (1984), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Robinson & Terborgh (1997), Salaman (1994), Sick (1993, 1997), Skutch (1985), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Willis (1980), Zimmer (1939a).



Genus *NEOPIPO* P. L. Sclater & Salvin, 1869

218. **Cinnamon Tyrant**

Neopipo cinnamomea

French: Moucherolle manakin **German**: Zimtbauch-Pipratyrann **Spanish**: Mosquerito Canelo
Other common names: Cinnamon Neopipo/Manakin/Tyrant-manakin

Taxonomy. *Pipra* [*sic*] *cinnamomea* Lawrence, 1869, Chamicuros, Peru.
Formerly considered a manakin and placed in the family Pipridae, but anatomical and other features typical of present family; appears most closely related to a group that includes *Myiophobus*, *Myiobius*, *Terenotriccus*, *Pyrrhomyias* and *Hirundinea*. Validity of race *helenae* questionable; further research required. Two subspecies currently recognized.
Subspecies and Distribution.
N. c. cinnamomea (Lawrence, 1869) - E Ecuador, E Peru, E Colombia, S Venezuela and W & C Amazonian Brazil.
N. c. helenae McConnell, 1911 - the Guianas and N Brazil (Amapá).
Descriptive notes. 9·1-9·5 cm; 7 g. Small, short-tailed flycatcher with large eyes, no rictal bristles. Has dull grey crown with semi-concealed yellow coronal patch, dull grey head side, nape and back, rufous rump; wing feathers dusky with broad rufous edges, tail rufous; throat and underparts buffy to orange-cinnamon, palest on throat; iris dark; bill narrow, black, lower mandible with orange base; legs blue-grey or dusky grey. Distinguished from similar *Terenotriccus erythrurus* by smaller size, short tail and rounded head, dark legs, no rictal bristles. Sexes similar, female duller orange-rufous than male, coronal patch smaller. Races are very similar. Voice. Call a short, wheezy whistled "pfééeo" or "weeo", rising and then falling. Song, often repeated from single perch for 5-10 minutes, a series of 10-15 notes, e.g. "pee pee pa pee... fe-fée-fee-feaa-feaa-feaa-feaa-feaa", slowly

over 5-6 seconds, second note lowest, fifth highest, subsequent notes gradually descending the scale; reminiscent of song of Southern Nightingale-wren (*Microcerculus marginatus*) but faster.

Habitat. *Terra firme* forest, often in areas of white sandy soil in lowlands. Sea-level to c. 1000 m; to 200 m in Venezuela.

Food and Feeding. Arthropods. Forages mostly singly, usually apart from mixed-species flocks; has been observed while foraging with small mixed flock that included *Terenotriccus erythrurus*. Perches in understorey at middle levels or higher; posture usually hunched-looking. Makes frequent rapid sallies to undersides and edges of leaves.

Breeding. No information.

Movements. Probably resident.

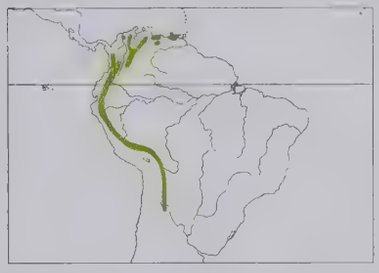
Status and Conservation. Not globally threatened. Rare and local throughout range; perhaps often overlooked. Appears to occur at low densities in comparison with other small avian insectivores of forest interior; relatively few records from W Amazonia, and poorly known in Peru. Occurs in Cuyabeno Reserve and Jatun Sacha Biological Station, in Ecuador, and Rio Cristalino Forest Reserve and Tapajós National Park, in Brazil. Much of this species' habitat remains in relatively good condition within its fairly large range, although numbers reduced wherever habitat destruction has taken place.

Bibliography. Álvarez & Whitney (2003), Butler (1979), Carrión & Sibley (1992), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Mobley & Prum (1995), Novaes (1978a), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Snyder (1966), Willard *et al.* (1991).

Genus *PYRRHOMYIAS* Cabanis & Heine, 1859

219. **Cinnamon Flycatcher**

Pyrrhomyias cinnamomeus



French: Moucherolle cannelle **German**: Zimttyrann **Spanish**: Birro Chico

Taxonomy. *M[uscipeta] cinnamomea* d'Orbigny and Lafresnaye, 1837, Yungas, Bolivia.

Closely allied to *Neopipo* and *Hirundinea*. Differences among races *vieillotioides*, *spadix* and *pariae* appear subtle at best, and these taxa perhaps should be merged; differences between nominate and *pyrrhopterus* also slight, and may reflect clinal variation from N to S within Andes. Six subspecies currently recognized.

Subspecies and Distribution.

P. c. assimilis (J. A. Allen, 1900) - N Colombia (Santa Marta).
P. c. vieillotioides (Lafresnaye, 1848) - NW Venezuela.
P. c. spadix Wetmore, 1939 - mountains of NC & NE Venezuela.
P. c. pariae Phelps, Sr & Phelps, Jr, 1949 - Paria Peninsula, in NE Venezuela.
P. c. pyrrhopterus (Hartlaub, 1843) - Andes of W Venezuela, Colombia, Ecuador and Peru.
P. c. cinnamomeus (d'Orbigny & Lafresnaye, 1837) - Andes of E Peru, Bolivia and NW Argentina.

Descriptive notes. 11-13 cm; 10·8 g. Overall cinnamon-rufous, with peaked crown. Nominate race has dark brownish crown, semi-concealed yellow coronal patch, indistinct buffy supraloral patch and eyering; cheek, nape and upperparts olive-brown, rump with narrow cinnamon-orange band (often hidden); wings black, two broad rufous wingbars, rufous edgings on remiges forming large panel on secondaries; tail blackish; throat, neck side and underparts cinnamon-rufous, slightly paler on belly; iris dark; bill fairly broad, black; legs blackish. Sexes alike. Juvenile is browner, lacks yellow coronal patch, has ochraceous-tipped feathers on lower back and tail. Races vary in plumage, and perhaps best described in three groups: in Andean group, *pyrrhopterus* is very similar to nominate, but differs in having crown tinged olive, back all olive, rump band brighter orange-yellow, also perhaps smaller in size; N group comprises *vieillotioides*, *spadix* and *pariae*, all very similar, differ from nominate group in having reddish-brown crown, rufescent-brown back that may shade to olive on upper rump (just above band), extensive rufous webbing in rectrices, perhaps slightly paler or duller breast, and small amounts of rufous edging at base of primaries; isolated Santa Marta (N Colombia) race *assimilis* is quite distinct from all others, brighter and warmer both above and below (the most cinnamon of all races), crown reddish-brown and more rufous than N group, back orange-rufous, very narrow olive band on upper rump above orange-buff band, rectrices entirely rufous with dark brown subterminal band, primary bases with slightly more rufous than in N group. Voice. Call a rattling trill, "trrrt", "tr-r-r-r-r-r", "pti-i-i-i-i" or "pit, pit-pit-pit", repeated frequently at short intervals; flight call "tjip tjip"; also single "pit", "tsip" or "chip" notes.

Habitat. Clearings, borders and roadcuts in montane forest and woodlands; 600-3550 m, usually 1200-3000 m. In Ecuador occurs on both slopes of Andes and locally above C and inter-Andean valleys.

Food and Feeding. Insects, also some berries. Often forages in pairs; joins, but does not follow, mixed-species flocks. Searches for prey from exposed horizontal perch 1-15 m up on edge of forest, but not in tops of trees; perches upright. An aerial hawker, captures aerial prey in short sallies, abruptly returning to same perch.

Breeding. Apr-May in N Venezuela. Nest an open cup made of moss and lichen, placed 1-5 m above ground in crevice, niche or ledge of rock, fallen log or bark of tree; pair maintains small permanent territory. Clutch 2 eggs; no other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common; one of commonest flycatchers in montane forest. Occurs in Henri Pittier National Park, in Venezuela, Tambito Nature Reserve, in Colombia, and all protected areas in humid Andes from Ecuador S to Bolivia, and in Calilegua National Park, in Argentina. Has unusually wide elevational range; in Ecuador, occurs on both slopes of Andes and locally above C & inter-Andean valleys. Seems fairly adaptable, and persists even in partially deforested regions.

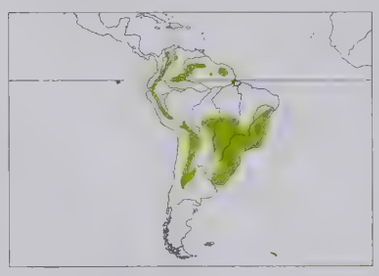
Bibliography. Allen (1998), Baez *et al.* (1997), Bond *et al.* (1989), Canevari *et al.* (1991), Collins & Ryan (1995), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fitzpatrick (1985a), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Mobley & Prum (1995), Moynihan (1979), Narosky & Yzurieta (1993), de la Peña (1988), Perry *et al.* (1997), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodewald & Rodewald (2003), Ryan & Collins (1999), Salaman (1994), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Traylor & Fitzpatrick (1982), Walker (2001), Wetmore (1939), Williams & Tobias (1994), Zimmer (1930, 1939b).

Genus *HIRUNDINEA*

d'Orbigny & Lafresnaye, 1837

220. **Cliff Flycatcher**

Hirundinea ferruginea



French: Moucherolle hirondelle **German**: Schwalbentyrann **Spanish**: Birro Común
Other common names: Swallow Flycatcher (*bellicosa*)

Taxonomy. [*Todus*] *ferruginea* J. F. Gmelin, 1788, Cayenne.

Closely allied to *Neopipo* and *Pyrrhomyias*. Four subspecies recognized.

Subspecies and Distribution.

H. f. sclateri Reinhardt, 1870 - W Venezuela and S on E slope of E Andes from Colombia to SE Peru (S to Cuzco).
H. f. ferruginea (J. F. Gmelin, 1788) - Disjunctly in extreme E Colombia (R Vaupes), NW Brazil (NW Amazonas), SE Venezuela (Bolívar), SW Guyana and French Guiana.
H. f. pallidior Hartert & Goodson, 1917 - N & E Bolivia, W Paraguay and NW Argentina (S to La Rioja and Córdoba).
H. f. bellicosa (Vieillot, 1819) - S & E Brazil, E Paraguay, NE Argentina (Misiones) and Uruguay.

Descriptive notes. 15·5-18·5 cm; 21 g. Long, slender tyrannid reminiscent of a swallow (Hirundinidae), with short rictal bristles, long pointed bill broad at base, short legs; triangular wings in flight. Nominate race has crown and upperparts blackish-brown, cheek mottled white, whitish short supercilium, dark loral stripe; wings blackish when folded (sometimes showing rufous inner webs as panel in secondaries or inner primaries), in flight primaries and secondaries with broad rufous band bordered by blackish feather tips; tail blackish above, inner webs rufous (except on central rectrices), cinnamon-rufous only at base below; chin mottled grey, throat and underparts, including underwing-coverts, uniform cinnamon-rufous; iris dark; bill blackish; legs black. Sexes similar. Races vary in coloration of, especially, crown and chin, wings and tail: *sclateri* is much like nominate, but with more extensive white mottling on head, especially forehead and crown, paler chin, more extensive rufous on inner webs of underside of rectrices; *bellicosa* is more rufous-brown above (rather than dark chocolate-brown), cheeks and chin brown with dusky mottling, conspicuous orange-brown rump and basal half of uppertail, conspicuous rufous edging and panel on closed wing, margins of wing-coverts and tertials buff to pale brown; *pallidior* resembles previous, but rufous margins in wing slightly wider, rufous extends less far down tail (creating broader dark subterminal band). Voice. Frequently gives high-pitched calls or single or repeated notes described as "wheeeyp", "killy killy", "kaleé kale" or "wha-deép wha-deép"; dawn song a repeated rapid high "kit-ti-léé".

Habitat. Cerros, cliffs, rocky outcrops, canyon walls, landslides and steep banks bordered by mature and secondary forest, as well as similar, man-made habitats such as roadcuts, bridges and quarries; also more sparsely wooded slopes or dry valleys in Bolivia, and uses ledges and facades of buildings in Brazil. Lowland populations occur from sea-level to 2000 m; Andean populations mainly 900-2000 m, but locally as high as 3900 m in Bolivia.

Food and Feeding. Insects. Often forages in pairs or family groups. Unique in family, captures prey by hawking in spectacular, powerful, long aerial sallies; usually returns to same perch; swoops and glides in flight much like a swallow. Usually perches horizontally, searching for prey from exposed perch on rocky outcrop, cliff face, overhanging branch or twig, small bush or tree growing out of cliff face, or large canopy tree bordering cliff; also from wires and buildings in urban areas.

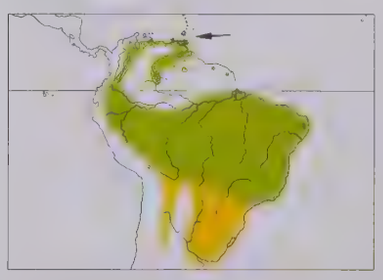
Breeding. Nest found in Nov in Argentina; juvenile reported in Dec in Bolivia (Cochabamba). Nest an open cup made of grass, one with internal diameter 7 cm, external diameter 9 cm, depth 2 cm, placed in crevice or on ledge of cliff or roadcut. Clutch 2 eggs; no information on incubation and fledging periods; distraction display by adults when nest threatened.

Movements. Mainly resident. S breeders migrate during austral winter, sometimes far from typical habitat.

Status and Conservation. Not globally threatened. Fairly common but local. Probably increasing and spreading into artificially created habitats associated with newly constructed roads. Occurs in Alto Orinoco-Casiquiare Biosphere Reserve and Canaima National Park, in Venezuela, Machu Picchu Historical Sanctuary, in Peru, Noel Kempff Mercado National Park, in Bolivia, Aparados da Serra, Itatiaia, Serra da Canastra and Tijuca National Parks, all in Brazil, and Cerro Corá National Park, in Uruguay.

Bibliography. Canevari *et al.* (1991), Clements & Shany (2001), Cory & Hellmayr (1927), Davies *et al.* (1994), Fitzpatrick (1985a), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Joseph (1996), Mobley & Prum (1995), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1987, 1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor & Fitzpatrick (1982), Walker (2002), Zimmer (1930).

Genus *LATHROTRICCUS*



W. E. Lanyon & S. M. Lanyon, 1986

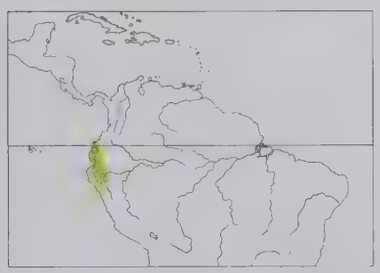
221. **Euler's Flycatcher**

Lathrotriccus euleri

French: Moucherolle d'Euler **German**: Euler-Schnäppertyrann **Spanish**: Mosquero de Euler

Taxonomy. *Empidochanes Euleri* Cabanis, 1868, Cantagalo, Rio de Janeiro, Brazil.
Genus formerly included within *Empidonax*. If present species is included in *Empidonax*, name *flaviventris* becomes preoccupied, and must give way to *johnstonei* for Grenada birds; those from Trinidad also, independently, named as *flavirostris* (by same author, in same year!), but that name, preoccupied in both genera, gives way to *lawrencei*. Five subspecies recognized.
Subspecies and Distribution.
L. e. flaviventris (Lawrence, 1887) - Grenada, in S Windward Is (probably extinct).
L. e. lawrencei (J. A. Allen, 1889) - Trinidad, W & N Venezuela, locally E Colombia, also casually Surinam and French Guiana.
L. e. bolivianus (J. A. Allen, 1889) - S & SE Venezuela, E Ecuador, E Peru, much of Brazil (except N & SE) and NW Bolivia; some possibly migrate to Colombia.
L. e. argentinus (Cabanis, 1868) - E Bolivia, N Argentina and Paraguay; migrates N into Amazonia of E Peru and E Brazil.
L. e. euleri (Cabanis, 1868) - SE Brazil, NE Argentina and Uruguay ; migrates N into Amazonia of NE Peru, Bolivia and Brazil.

Descriptive notes. 12·7-13·5 cm; 11 g. Generally drab, similar to some *Empidonax* species, but browner above and buffier wingbars. Nominate race has warm olive-brown crown, whitish eyering and indistinct supraloral stripe; cheek, nape and back olive-brown, rump brown; wings dusky, two pale buff wingbars, pale buffy-brown margins of secondaries and tertials; tail dusky; throat greyish-white, breast washed brownish-olive, belly pale yellow to white; iris dark; upper mandible black, lower mandible flesh-coloured; legs blackish-brown. Sexes similar. Races vary in size and colour: *argentinus* is similar to nominate but with whitish throat, drabber grey breast, white belly; *lawrencei* is more olive above, breast olive-grey, yellower on belly; *bolivianus* is slightly less olive above than previous, pale olive-grey breast,



perhaps less yellow belly, juvenile browner than adult and with slightly buffier wingbars; *johnstonei* is little known, generally similar to nominate except that wingbars vary to more reddish-brown than buff, breastband greyer. Voice. Song an abrupt and buzzy "fééú! pe'pe'pe'p'p", first note loudest and second part descending scale; also described as fast burry "peeeur, peer-per-per-peeur", sometimes limited to just first note, or even faster versions as "peeeur, peepiti" or "bew-bewee"; in Brazil, song described as "shpaye-shpaye-wileh" and call is a muffled "béách-bich".
Habitat. Lower levels of moist and humid forest, secondary growth, and open forest borders; sometimes in bamboo thickets. From sea-level to 1500 m, possibly higher in some locations.
Food and Feeding. Arthropods, especially beetles (Coleoptera), ants (Hymenoptera), homopteran bugs (planthoppers and cicadas), and assorted dipterans, Hemiptera and arachnids. Generally alone or in pairs; rarely joins mixed-species flocks. Searches for prey from low, usually inconspicuous perch in shady undergrowth; captures prey by sallying to foliage, returning to same perch or moving to new one.
Breeding. Breeds May-Jul in Trinidad, Sept-Nov in Brazil and Oct-Nov and Jan in Argentina. Nest a cup lined with soft black fibres, one with external diameter 5 cm, height 6 cm, internal depth 2·5 cm, placed generally 1-2 m up on branch or in fork, or over small hole or knothole. Clutch 2-3 eggs; no information on incubation and fledging periods.
Movements. Mainly resident. Race *argentinus* and S populations of nominate migrate N into Amazonia during austral winter, becoming locally numerous in SE Peru; austral migrants possible, but hitherto unrecorded, in Venezuela and Ecuador; timing, routes and boundaries of migration not well understood.
Status and Conservation. Not globally threatened. Uncommon to locally common; becomes less numerous and widespread in N part of range, e.g. much more scarce in Colombia and Ecuador. Grenada race (*flaviventris*) not recorded since 1950, probably extinct. Otherwise, because of the species' large range, it occurs in many national parks and other protected areas, e.g. Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, Beni and Pilón Lajas Biosphere Reserves and Madidi and Noel Kempff Mercado National Parks, in Bolivia, Cerro Corá National Park, in Uruguay, and Calilegua National Park, in Argentina, as well as in seven national parks in Brazil and four in Paraguay. Regularly seen above Maracay, along Choroní road in Venezuela.
Bibliography. Aguilar *et al.* (1999), Anon. (1998a), Banks (1997), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Di Giacomo (2004), Faaborg (1985), ffrench (1991), Fitzpatrick (1980a), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Joseph (1996), Klimaitis & Moschione (1987), Lanyon & Lanyon (1986), Lowen *et al.* (1996), Miserendino (1998), Narosky & Salvador (1998), Oren & Parker (1997), de la Peña (1988), Perry *et al.* (1997), Raffaele *et al.* (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Temple (2002), Tostain *et al.* (1992), White (2002), Zimmer (1930, 1939a).

222. **Grey-breasted Flycatcher**

Lathrotriccus griseipectus

French: Moucherolle à poitrine grise **Spanish**: Mosquero Pechigrís
German: Graubrust-Schnäppertyrann

Taxonomy. *Empidonax griseipectus* Lawrence, 1870, Puná Island, south Ecuador.
Genus formerly included within *Empidonax*. Monotypic.
Distribution. W slope of Andes in W Ecuador, and N Peru.

Descriptive notes. 13 cm; 11 g. Has grey crown, whitish broken eyering and supraloral stripe; cheek, nape, back and rump grey with slight brown or olive tinge; wings dusky, two well-marked whitish wingbars, whitish margins of secondaries and tertials; tail dusky; throat greyish-white, breast washed darker grey, belly white to whitish with pale yellow tinge; iris dark; upper mandible black, lower mandible pale orange-yellow; legs blackish. Sexes similar. Voice. Song a variable and fast burry "peeéur, peer-per-per-pur", similar to that of *L. euleri*.
Habitat. Lower levels of humid and deciduous forest; sea-level to 2200 m, mainly below 1700 m, most numerous below 800 m.
Food and Feeding. Insects. Perches inconspicuously, at up to 4 m, in shady vine tangles and vegetation near sunlit forest gaps; captures prey with sallies out to air. Occasionally observed at army-ant swarms.
Breeding. Little known. Probably breeds during wet-season, Jan-May; immatures recorded in Mar.
Movements. Little information; some seasonal movement thought to occur, with some birds moving to more humid forest during dry season.
Status and Conservation. VULNERABLE. Restricted-range species: present in Tumbesian Region EBA and Marañón Valley EBA. Rare to locally fairly common. Range c. 13,800 km², and estimated population 2500-10,000 individuals and declining. Occurs at c. 36 localities in W Ecuador (in Esmeraldas, Pichincha, Manabí, Los Ríos, Guayas, Cañar, Azuay, El Oro and Loja) and NW Peru (in Tumbes, Piura, Lambayeque and Cajamarca). In Ecuador, the species is found regularly in Cerro Blanco Forest Reserve and Río Palenque Science Centre, is fairly common in Machalilla National Park, and is very common (up to 3 pairs/ha) in vine-rich forest at Jauneche Biological Reserve Station; Peruvian stronghold is the Northwest Peru Biosphere Reserve, where up to 6 individuals recorded per day. Recently recorded in Ecuador also at Manglares-Churute Ecological Reserve, at Manta Real (designated for protection), near Guayaquil, and fairly common at Loma Alta Ecological Reserve and Hacienda González (a private property in Cordillera de Chongón); the 776-km² partially forested Chongón-Colonche Protection Forest, which forms nucleus of a reforestation project, may also support the species. Habitat is threatened by illegal settling, deforestation and livestock grazing, even within protected areas. Forest below 900 m is especially threatened in this region, having undergone deforestation rates of 57% per decade from 1958 to 1988; losses continue, and threaten to eliminate all lowland forest outside protected areas in the region. Further conservation efforts within protected areas and research aimed at establishing a better understanding of this species' distribution, ecology and movements are recommended.
Bibliography. Begazo *et al.* (2001), Best & Clarke (1991), Best & Kessler (1995), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Hilgert & Benavides (2002), Meyer de Schauensee (1982), Parker & Carr (1992), Parker *et al.* (1995), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Wege & Long (1995), Williams & Tobias (1994).

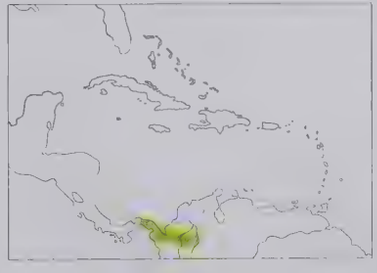
Genus *APHANOTRICCUS* Ridgway, 1905

223. **Tawny-chested Flycatcher**

Aphanotriccus capitalis

French: Moucherolle à poitrine fauve **Spanish**: Mosquero Pechileonado
German: Ockerbrust-Schnäppertyrann

Taxonomy. *Myiobius capitalis* Salvin, 1865, Tucurrique, Costa Rica.
Monotypic.
Distribution. Caribbean slope of E & SE Nicaragua and N Costa Rica.



Descriptive notes. 12 cm; 11 g. Resembles an *Empidonax* in appearance and posture, but more brightly coloured. Male has crown dark grey, dark lores, white supraloral stripe and broken eyering, greyish-olive cheek; nape and back olive-green, tinged ochraceous, rump olive-green; wings dusky, two bright ochraceous wingbars, ochraceous margins of secondaries and tertials; tail dusky olive; throat white, tinged buff at side, breast bright cinnamon-ochre, belly and undertail-coverts yellow; iris dark; upper mandible black, lower mandible pinkish or flesh-coloured at base, rest black; legs grey. Female has crown more olive-tinged. Juvenile not well known. Voice. Song a rapid "chee chee spt't cheew" or "chit it-it chee'yew", last note loudest; sometimes more extensive "choot choot choot ch-ch-ch-chttttree'ih", similar to song of Grey-headed Piprites (*Piprites griseiceps*).
Habitat. Dense vegetation near edges, natural clearings or streams within humid and mature secondary forest; also cacao plantations. Lowlands and foothills from sea-level to 900 m, locally to 1050 m.
Food and Feeding. Insects, especially beetles (Coleoptera), bugs (Hemiptera) and ants (Hymenoptera). Forages alone or in pairs, following regular routes; forages low in dense vegetation, using upward sallies to capture prey from undersides of leaves and branches. May spread and close tail upon landing.
Breeding. Little known. Apparently a crevice-nesting species; nests recorded c. 6 m above ground in hollows of large bamboo (*Guadua*) and non-native bamboo (*Alchornea*). No other information.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Central American Caribbean Slope EBA. Rare to uncommon, and local. Occurs within small range of c. 8000 km²; population estimated at fewer than 10,000 individuals, and declining as a result of extensive forest clearance and fragmentation. Although this species has been found in cacao plantations and similar areas, it does not persist in small forest fragments; threatened, therefore, by habitat destruction and fragmentation due to logging, banana cultivation and cattle-ranching. So far, all Nicaraguan records are based on historical specimens, but it potentially occurs within Río Indio-Maíz Biological Reserve. In Costa Rica, it is protected within Rincón de la Vieja National Park, La Selva Biological Reserve and Rancho Naturalista, and possibly occurs also within Braulio Carillo National Park; Rancho Naturalista is an ecotourism lodge, where the species receives protection under current management practices. Improved knowledge of its distribution, especially in Nicaragua, may result in the species' conservation status being downgraded to that of Near-threatened.
Bibliography. Anon. (1998a), Collar *et al.* (1994), Cory & Hellmayr (1927), Eisenmann (1955), Fitzpatrick (1980a), Howell (1957), Ridgway (1907), Slud (1960, 1964), Stattersfield & Capper (2000), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Young & Zook (1999).

224. **Black-billed Flycatcher**

Aphanotriccus audax

French: Moucherolle à bec noir **Spanish**: Mosquero Piquinegro
German: Schwarzschnabel-Schnäppertyrann

Taxonomy. *Praedo audax* Nelson, 1912, Cana, 2000 feet [c. 600 m], E Panama.
Monotypic.
Distribution. E Panama S locally to N Colombia.

Descriptive notes. 13·2 cm. Rather slender tyrannid; resembles *Empidonax* but bill and supraloral coloration distinctive and posture different. Male has crown olive-grey, shading to bright greenish-olive on back; white supraloral stripe and narrow broken eyering; wings dusky, two pale buff wingbars, short primary projection; tail relatively long, dusky brown; throat and underparts white, broad and indistinct olive wash on breast, becoming yellower on lower breast and belly; iris dark; bill short, black; legs blackish. Female and juvenile not well known. Voice. Song, given infrequently, a loud, sharply enunciated but wheezy or burry "bee béé, be-be-be-bez", "jee-jee-jew" or fainter "bee-beez-bez-baw".

On following pages: 225. Belted Flycatcher (*Xenotriccus callizonus*); 226. Pileated Flycatcher (*Xenotriccus mexicanus*); 227. Fuscous Flycatcher (*Cnemotriccus fuscatus*).

Habitat. Low and dense vegetation near streams and swamps within humid and mature secondary forest; sea-level to 600 m, usually from 100 m, and occasionally to 700 m.
Food and Feeding. Insects. Usually in pairs, often inconspicuous, and does not usually join mixed-species flocks. Perches 1-4 m up, searching for prey; often perches more horizontally than do *Empidonax* species. Captures prey by sallying or fluttering short distances to foliage, then continuing on to new perch.
Breeding. Male in breeding condition in Mar-Apr; juvenile observed late Jun. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Darién Lowlands EBA and Nechí Lowlands EBA. Uncommon to locally common, but perhaps often overlooked. Appears to be declining as a result of habitat destruction and conversion to agriculture following road-building. In Panama, found in Darién National Park and recorded regularly along Boca de Cupe trail near Cana (E Darién); fairly common in Río Verde del Sinú, in Colombia.
Bibliography. Anon. (1998a), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Eisenmann (1955), Haffer (1975), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Wetmore (1972).

Genus *XENOTRICCUS* Dwight & Griscom, 1927

225. **Belted Flycatcher**

Xenotriccus callizonus

French: Moucherolle ceinturé **German**: Brustband-Schnäppertyrann **Spanish**: Mosquero Fajado

Taxonomy. *Xenotriccus callizonus* Dwight and Griscom, 1927, Panajachel, 5500 feet [c. 1675 m], Lake Atitlán, Guatemala.
Monotypic.
Distribution. Interior and adjacent Pacific slope of S Mexico (Chiapas) S locally to NW El Salvador.

Descriptive notes. 11·5-12·5 cm. Distinctive, crested flycatcher. Has olive crown with usually obvious spiked erectile crest; pale lores and pale lemon, teardrop-shaped eyering; nape greyish-olive, upperparts brownish-olive; wings dusky, two cinnamon wingbars, cinnamon margins of remiges forming panel on secondaries (but bases of remiges dark); tail dark grey-brown, outer webs of outer rectrices pale grey; throat whitish, broad cinnamon band across breast, contrasting pale lemon belly; iris dark; upper mandible black, lower mandible orange-flesh; legs dark grey. Sexes similar. Juvenile is similar to adult, but crest shorter. Voice. Call a buzzy nasal "rreah" or "choi-ih", sharper "cheuh" and burry "pi'kweehr"; song an accelerating and often quickly repeated "pic pi-pi-pi-pi-chi-i-weer" or "chi-chi-chi-chi-i-ir".
Habitat. Understorey of dense, scrubby woodland, especially with oaks (*Quercus*); highlands from 1200 m to 2000 m.
Food and Feeding. Insects. Usually remains well hidden, and best detected by voice. Forages by searching from low perch, and then sallying out to capture prey from the air or foliage.
Breeding. Nest a cup made of fine grass and other plant fibres, placed low in fork of shrub. Clutch 3 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in North Central American Highlands EBA. Uncommon and locally distributed, with small range in S Mexico, Guatemala and extreme NW El Salvador. Most common at El Sumidero, in Chiapas (Mexico), and not well known beyond this location. Habitat is threatened by widespread logging and by conversion for coffee cultivation, as well as by uncontrolled fires.
Bibliography. Anon. (1998a), Blake, E.R. (1953), Ceballos & Valdelamar (2000), Collar *et al.* (1994), Eisenmann (1955), Fitzpatrick (1980a), Howell & Webb (1995a), Land (1970), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Thurber *et al.* (1987).

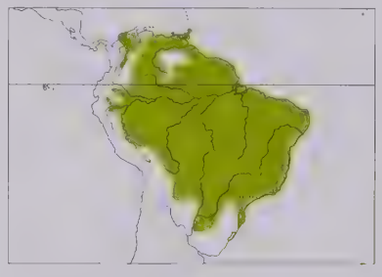
226. **Pileated Flycatcher**

Xenotriccus mexicanus

French: Moucherolle aztèque **Spanish**: Mosquero del Balsas
German: Schopfschnäppertyrann
Other common names: Crested Wood Pewee

Taxonomy. *Aechmolophus mexicanus* J. T. Zimmer, 1938, Cuernavaca, 5000 feet [c. 1525 m], Mexico.
Monotypic.
Distribution. SW Mexico, from C Michoacán and Morelos E to Oaxaca (W of Isthmus of Tehuantepec); recently found in NW Guatemala.
Descriptive notes. 13·5-14·5 cm. Distinctive, crested flycatcher, similar to *Empidonax* but more heavily built, longer-tailed, stouter-billed. Has greyish or brownish-olive crown with spiky erectile crest (usually raised, sometimes held flat); pale lores and white teardrop-shaped eyering; nape and upperparts greyish or brownish-olive; wings darker than back, two whitish wingbars, whitish margins of remiges forming indistinct panel on secondaries; tail dusky; throat white, breast washed grey, belly white with yellow tinge; iris dark; upper mandible black, lower mandible orange-flesh; legs dark grey. Sexes similar. Juvenile has shorter crest than adult, wingbars and margins of remiges buff; attains adult plumage quickly. Voice. Calls include nasal "brree" notes, richer more explosive "checoo" or "cheeup" notes, also harsher "whee whee-eu' whee-eu' whee-eu" possibly as alarm; song, from conspicuous perch, sputtered and intensifying "p'iweer pi-pi-pirrr-i-it' cheeu", or "wheeu whirr-rr-rr-rr-whee-u" reminiscent of a sport referee's whistle.
Habitat. Low to middle levels of arid montane scrub, mesquite and thorn-forest, occasionally in semi-open overgrazed areas; usually 900-2000 m.

Food and Feeding. Insects. Forages by searching from low perch, in fairly erect posture; jerks tail up in manner of *Empidonax oberholseri*. Sallies out to capture prey from the air or foliage; flight direct and heavy.
Breeding. Nest made of grasses and other plant fibres, often with trailing grass streamers, saddled in fork low in thorny thicket, and bound to fork by spider silk. Clutch 2-3 eggs. No other information.
Movements. Movements not well known. Mostly resident, but may descend in winter to lower elevations of the Balsas drainage; e.g. common at Monte Alban (Oaxaca) during summer, but rare or absent in winter.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Balsas Region and Interior Oaxaca EBA. Recent record from Laguna del Tigre National Park, in Guatemala, thus considerably extending its range. Habitat threatened by expansion of cattle-ranching and of coffee and citrus plantations. Very few protected areas exist within its small range.
Bibliography. Anon. (1998a), Blake, E.R. (1953), Ceballos & Valdelamar (2000), Collar *et al.* (1994), Fitzpatrick (1980a), Howell & Webb (1995a), Hutto (1992), Rowley (1984), Stattersfield & Capper (2000), Stotz *et al.* (1996).



Genus *CNEMOTRICCUS* Hellmayr, 1927

227. **Fuscous Flycatcher**

Cnemotriccus fuscatus

French: Moucherolle fuligineux **Spanish**: Mosquero Parduzco
German: Augenstreif-Schnäppertyrann

Taxonomy. *M[uscipeta] fuscata* Wied, 1831, no locality = probably Rio de Janeiro, Brazil.
Probably most closely related to *Lathrotriccus*. Some authorities suggest that more than one species may be involved, because of variation in plumage, voice and behaviour (particularly with regard to races *duidae* and *bimaculatus*); conversely, some races possibly unwarranted; further research required in order to clarify true taxonomic status of races. Seven subspecies currently recognized.
Subspecies and Distribution.
C. f. cabanisi (Léotaud, 1866) - N & E Colombia, and NW & N Venezuela, Trinidad, Tobago, Monos I and Chacachacare I.
C. f. duidae J. T. Zimmer, 1938 - S Venezuela and NW Brazil.
C. f. fumosus (Berlepsch, 1908) - the Guianas and NE Brazil.
C. f. fuscatior (Chapman, 1926) - SW Venezuela, SE Colombia, E Ecuador, E Peru and C Brazil.
C. f. beniensis Gyldenstolpe, 1941 - N Bolivia.
C. f. bimaculatus (d'Orbigny & Lafresnaye, 1837) - C Bolivia, S & E Brazil, Paraguay and N Argentina.
C. f. fuscatus (Wied, 1831) - SE Brazil and NE Argentina.

Descriptive notes. 13·5-15 cm; 11·9 g. Nominate race has crown and upperparts plain brown with slightly rufescent tone; whitish supraloral line and long thin supercilium extending behind eye, contrasting dusky lores and eyeline; wings dusky, two broad buffy wingbars, inner secondaries narrowly edged buff, tertials edged whitish; tail unusually long, dusky, edged brown; throat whitish, breast olive-grey or greyish-brown, belly pale yellow; iris blackish; bill long, narrow, mostly black, base of lower mandible pale flesh-coloured; legs black. Sexes similar. Juvenile not well known. Races vary mainly in extent of supercilium, extent and intensity of wingbars, colour of upperparts (from greyish to brownish) and colour of belly (from whitish to yellowish): *cabanisi* has two colour phases, one with greyish upperparts and white belly (apparently more numerous in interior of Venezuela), other with brown upperparts and yellow belly (more numerous in coastal and Tobago populations); *fumosus* is supposedly intermediate between previous and following races; *bimaculatus* is similar to nominate but with dull brownish-grey breast and white belly; *beniensis* resembles last; *duidae* has dark brown crown and back, rich olive-brown breast, pale yellow belly, and lower mandible entirely pale orange-yellow; *fuscatior* has dark brown crown and back similar to last, but breast less rich olive-brown, belly perhaps yellower, bill all dark. Voice. Call a muffled "aag-aag-aag" or frog-like "bsh-bsh-bsh" in Brazil; "feétz-beeu" in Venezuela, also as "pfééó" and "pfeeu-pfeeu-pfeea" in SE Sucre. Song a quick buzzy "jaw-jew-jew-jew jew" in Venezuela (Apure); elsewhere in range, a series of clear notes varying from "chip, weety-weety-weety, cheedip" to "chewy-chewit-cheepeer"; *bimaculatus* gives distinct single whistled "ooooooee", rising at end. Dawn song a rolling "pü-breeer-breeer" in Venezuela (Apure); in Andes, series of excited "p-pit-pit-péédit" phrases; high clear dawn song of *duidae* distinct, loud and whistled "chueeeeeeééééchueeét" or "chueeéé" and softer "chuéééchee", repeated. Often vocalizes late into morning or midday hours.
Habitat. Shady and thick undergrowth vegetation in variety of habitats, often near water, including thickets within dry, humid and gallery forests, second growth, *várzea*, and on river islands. Sea-level to 900 m, mainly below 500 m; below 250 m S of Orinoco in Venezuela; race *bimaculatus* recorded to 2400 m in Bolivia (La Paz).
Food and Feeding. Insects. Forages quietly, alone or in pairs (partners well separated), rarely joining mixed-species flocks. Searches from perches usually from near ground to 3 m up, sometimes higher; fairly horizontal posture (unlike *Empidonax*). Captures prey by sallying short distances to foliage or ground, sometimes hover-gleaning insects from underside of leaves.
Breeding. Apr-May in Trinidad, and nests found in Feb and Jul in Tobago; nest with egg in Nov in Argentina; nest-building and nests with chick in Nov in Brazil. In Trinidad, nest a cup made of twigs and bark, lined with black fibres, placed 3 m up in tree fork. Clutch 3 eggs. No other information.

Movements. Mainly resident. Details of any migratory behaviour generally not well known. S Brazilian populations believed to be migratory; race *bimaculatus* recorded at high elevations in La Paz (Bolivia) in Sept-Oct, and rare during austral winter in Paraguay.
Status and Conservation. Not globally threatened. Uncommon to common, and widespread in much of South America E of Andes. Accepts a variety of wooded habitats, and therefore occurs in many national parks and other protected areas throughout its extensive range.

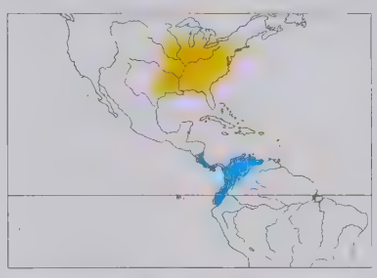
Genus *EMPIDONAX* Cabanis, 1855

228. Yellow-bellied Flycatcher

Empidonax flaviventris

French: Moucherolle à ventre jaune **Spanish**: Mosquero Ventriamarillo
German: Birkenschnäppertyrann

Taxonomy. *Tyrannula flaviventris* W. M. Baird and S. F. Baird, 1843, near Carlisle, Pennsylvania, USA.
Suggested as possibly closest to *E. wrightii* and *E. difficilis*/*E. occidentalis*. Monotypic.
Distribution. Breeds W Canada from C & N British Columbia and WC & S Mackenzie E to Newfoundland, Prince Edward I and Nova Scotia, and S into NE USA (E from N Minnesota and Great Lakes region, S into Pennsylvania, C New York, and disjunctly in West Virginia). Winters from SE & SW Mexico (on Caribbean slope from S Tamaulipas, on Pacific slope from Oaxaca) S to W Panama.



Descriptive notes. 12·5-15 cm; 9-16 g. Adult has rounded crown greenish-olive, slightly crested; pale olive supraloral area, pale yellow complete eyering; head side, nape and back greenish-olive, rump olive-green; wings blackish-brown, two broad wingbars white to pale yellow, white to pale yellow margins on secondaries and tertials (forming pale panel on secondaries of closed wing); moderate primary projection; tail relatively short and narrow, rectrices dusky brown, edged greenish-olive; throat yellow, breast extensively washed olive, belly and undertail-coverts yellow; plumage varies with wear, brightest green above and yellowish on wing margins and below in spring (fresh plumage), drabber olive above with whiter wing margins and paler and whiter below by late summer (worn plumage); iris dark; bill short, broad, upper mandible black, lower mandible pinkish-yellow, mouth-lining orange; legs dark grey, feet blackish. Distinguished from *E. virescens* by smaller bill, wing morphology (especially shorter primary projection), shorter tail, yellower underparts, brighter mouth coloration; from *E. difficilis* and *E. occidentalis* by brighter upperparts, wing morphology, more rounded eyering. Sexes similar. Juvenile is similar to adult, but wingbars with buffy tinge. Voice. Song, often from prominent perch 3-10 m up, an abrupt "killionk" or "che-bunk", also described as e.g. "killic", "pee-wick", "pse-ek", "che-lek", "pschee-ik" or similar, or as more leisurely "peeup" or "pee-eep"; also shorter "sclek", "psek" or "kik" version of song, reminiscent of call of Downy Woodpecker (*Picoides pubescens*). Call an ascending whistled "tu-wee", also by female from nest; abrupt burry "brrrt", "prit" or "chirr" in flight during aggressive encounters, territorial conflicts (both during breeding and in winter), and after prey capture; also a "chip" note. Bill-snapping reported during aggressive encounters.
Habitat. Breeds in coniferous and mixed forests, bogs, swamps and muskegs, often in moist areas with thick moss and dense undergrowth; dominant trees include black spruce (*Picea mariana*), balsam fir (*Abies balsamea*), hemlock (*Tsuga*), pine (*Pinus*) or larch (*Larix*), and understorey shrubs include blueberry (*Vaccinium*), swamp azalea (*Rhododendron viscosum*), sheep laurel (*Kalmia angustifolia*), Labrador tea (*Ledum groenlandicum*), heaths (Ericaceae) and others. Restricted to higher elevations where appropriate spruce or bog habitat persists in S portion of breeding range (in the Catskills, Adirondacks, Tug Hill Plateau, Appalachians). During migration, inhabits dense vegetation in riparian and upland deciduous forests. In winter, inhabits dense vegetation in variety of habitats including rainforest, montane evergreen forest, pine-oak forests, forest borders, and secondary forest, sometimes near streams; also reported from palm forests and plantations of coffee and cardamum in Guatemala; fares better in shade coffee than in sun-grown coffee.
Food and Feeding. Insects and other arthropods; occasionally fruit. On breeding grounds, diet includes flying ants (Hymenoptera), small beetles (Coleoptera), dipterans including midges (Chironomidae), stoneflies (*Lectuira*), craneflies (Tipulidae) and mosquitoes (Culicidae), also spiders (Araneae), larval lepidopterans, bugs (Hemiptera); fruit includes poison ivy (*Rhus radicans*). Perches upright, occasionally jerks tail up. Forages in understorey, by searching from perch; prey captured from air, foliage or occasionally the ground, by hawking, sallying or gleaning; usually returns to a new perch.
Breeding. Late May to early Aug. Nest constructed by female, a hollowed-out depression lined with grass, black rootlets and conifer needles, average outside diameter of nest cup 8·13 cm, depth 9·6 cm, inside diameter 5·3 cm, depth 4·0 cm; on or near ground in cool, moist shady place, hidden from above by dense vegetation (including moss, herbs, sedges, ferns, shrubs and small trees), often imbedded in *Sphagnum* moss or at base of ferns, or under tree roots, embankment, within log or at base of overleaning tree trunk. Clutch 3-5 eggs, usually 4; incubation period 15 days; fledging period 13 days. Breeds in first season after hatch. Longevity record 4 years (based on 16 recoveries).
Movements. Long-distance migrant, wintering in Central America. Migrates at night through E USA to C Great Plains and C Texas. Departs breeding grounds late Aug to late Sept, passing through Mexico Aug-Sept, through Costa Rica late Aug-Oct, and arriving Panama by Sept; leaves wintering grounds in Costa Rica Mar to mid-May, Panama by late Apr, migrating through Mexico Apr-May. Rare transient in Cuba during Apr. Vagrants reported from W North America and Greenland. Longer-winged male tends to arrive on breeding grounds 4 days earlier than female.
Status and Conservation. Not globally threatened. Fairly common. Difficult to census owing to inaccessible breeding habitat, but global population estimated at 6,200,000 individuals. Population trends appear mixed and subtle. Average densities may reach 30 territorial males/km² in spruce forests with no budworm infestation in Ontario, whereas density may be 50% lower in mature red spruce forest in Maine or young spruce forest in Nova Scotia. Common in continuous habitat in Canada, one of the most common birds in balsam-fir forests in Newfoundland; perhaps less secure in more fragmented range in NE USA, where spruce die-offs, acid rain and ski-resort development may have reduced available habitat. Although tolerant of modest habitat disturbance on non-breeding grounds, loss of forest through conversion for agriculture in much of the tropics is of concern for this species; wintering populations near Tuxtla Mts (Veracruz), in Mexico, have declined as a result of habitat conversion.
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Beal (1912), Bent (1942), Binford (1989), Brunton & Crins (1975), Campbell *et al.* (1997), Cory & Hellmayr (1927), Cyr & Larivée (1995), DeGraaf & Rappole (1995), Dunn *et al.* (1999), Erskine (1977), Fitzpatrick (1980a), Garrido & Kirkconnell (2000), Greenberg *et al.* (1997), Gross & Lowther (2001), Hespenheide (1980), Howell & Webb (1995a), Johnson (1963a), Kaufman (1990, 1996), Lee Jones (2004), Mengel (1965), Monroe (1968), Peck & James (1987, 1997), Peterjohn *et al.* (1995), Peterson (1988b), Petit *et al.* (1993), Prescott (1987), Price *et al.* (1995), Pyle (1997b), Raffaele *et al.* (1998), Ramos (1988), Rappole (1992), Rappole & Warner (1980), Rappole *et al.* (1992), Ridgely & Gwynne (1989), Ridgway (1907), Sauer & Droege (1992), Sibley (2000), Skutch (1977), Slud (1964), Stickney (1923), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Walkinshaw (1967), Walkinshaw & Henry (1957), Warkentin *et al.* (1995), Wetmore (1972), Whitney & Kaufman (1986).

229. Acadian Flycatcher

Empidonax virescens

French: Moucherolle vert **German**: Buchenschnäppertyrann **Spanish**: Mosquero Verdoso

Taxonomy. *Platyrhynchos virescens* Vieillot, 1818, no locality = near Philadelphia, Pennsylvania, USA. Monotypic.
Distribution. Breeds mainly E North America from SE South Dakota and Great Lakes region E to S Ontario and C New England, S to C Texas, Gulf Coast states, and C Florida. Winters from Caribbean slope of Nicaragua S & E along both slopes to Colombia, NW Venezuela and W Ecuador.

Descriptive notes. 13-14·5 cm; 12·2-14 g. Large, long-billed and long-winged *Empidonax*. Adult has olive-green crown, pale lores, white or yellowish-white narrow eyering, pale olive-green malar region; ear-coverts, nape and upperparts olive-green; wings blackish, two whitish to yellowish-white wingbars, whitish margins of secondaries and tertials (forming panel on secondaries of closed wing); very long primary projection (longest of genus); tail dusky; throat and underparts pale greyish-white, pale olive wash across breast, darkest on side, may appear faintly streaked; pale yellow wash or tinge on belly and undertail-coverts; plumage varies with wear, upperparts brightest green and wing margins and underparts yellowish in spring (fresh plumage), drabber olive above and whiter below and on wing margins by late summer (worn plumage); moults on breeding grounds before migration, throat sometimes tinged yellow, buffy wingbars retained during winter; iris dark; bill large, flat, longest and broadest of genus, upper mandible black, lower mandible pale orange-yellow; legs grey, uniquely in genus. Sexes similar. Juvenile resembles adult, but wingbars bright buff, also buff fringes on body feathers creating scalloped appearance (lost in partial moult in Jul-Sept). Differs from most congeners in larger size, uniformly green upperparts, leg coloration; from *E. flaviventris*, *E. occidentalis* and *E. difficilis* mainly in whiter underparts, wing morphology, mouth coloration. Voice. Common call, by both sexes throughout year, a sharp "pwit", "pweet" or "peet"; "whip-pee-wheer" call also heard in SC Indiana. Song, mostly by male during breeding season (occasionally by female when stressed), often from dead branch 2-20 m (usually 3-6 m) up, often over stream, edge of light gap, or near nest, distinctive and explosive "péét-sah" or "téé-chup". Dawn song a rapidly delivered series of "tee-chup" mixed with "seet", "spake" or similar metallic notes, begins at least 45 minutes before and continues to or past sunrise; sometimes unbroken for long or entire period. Evening song, from perch 20-25 m up and in flight, a series of "wseet" or "pseet" notes followed by "wheel chur", "queer queep" and other notes. Also slow trill by male while fluttering between perches ("Flutter call"), reminiscent of wing noise produced by Mourning Dove (*Zenaida macroura*); variety of additional soft calls by both sexes, including e.g. "pee-tul" by food-carrying male, "p-link" or "p-loink" during greetings. Bill-snapping by both sexes during aggressive encounters and in courtship.
Habitat. Breeds in mature deciduous and coniferous forests, often near water in river bottoms, ravines or near streams. Associated with bald cypress (*Taxodium distichum*) in S USA; tamarack (*Larix laricina*) swamps and mixed forest of deciduous trees and hemlock (*Tsuga canadensis*) in N portion of range (e.g. Wisconsin). Inhabits deciduous forests of beech (*Fagus*), maple (*Acer*), oak (*Quercus*), hickory (*Carya*); also black ash (*Fraxinus nigra*) swamps in Canada (S Ontario), and rhododendron-bordered streams in Tennessee and North Carolina. During migration uses wider variety of open and forest habitats, including young second growth, secondary and primary rainforest in Costa Rica; montane forest and second-growth pine-oak woodland in Mexico (Chiapas), and dry forest, forest borders and urban areas in Cuba and Bahamas. Winters in lowland forest or shady plantations (e.g. cacao), often in understorey, thickets and treefall gaps of primary or secondary forests. Generally sea-level to 1000 m; breeds mainly below 1000 m; occasionally as high as 2850 m (in Bogotá savanna, in Colombia) during migration; winters at 600-1200 m in Venezuela.
Food and Feeding. Arthropods; fruit also recorded. Diet when breeding includes beetles (Coleoptera), hymenopterans, homopteran bugs (aphids, hoppers, cicadas), moths (Lepidoptera), damselflies and dragonflies (Odonata), deerflies and horseflies (Tabanidae), mosquitoes (Culicidae), craneflies (Tipulidae), spiders (Araneae), harvestmen (Opiliones), also many types of larvae; diet similar on non-breeding grounds in Panama, but also includes cockroaches (Blattidae), true bugs (Hemiptera), termites (Isoptera), sowbugs (Isopoda), and melastome fruits (Melastomataceae). Generally does not follow mixed-species flocks, although commonly recorded following army-ant swarms in Panama. Perches upright, jerks tail up (perhaps not so much as do congeners), sometimes with wings slightly drooped; sits quietly, searching for prey in understorey, near ground, or within canopy. Most foraging activity 2-12 m up, sometimes as high as 20 m; males may forage higher than females. Captures prey by sallying out from perch to hawk, strike or hover-glean insects from undersides of leaves, mid-air, bark or occasionally from ground, often returning to same perch.
Breeding. Mid-May to early Aug; some pairs double-brooded, especially in extreme S of range. Nest built by female, average inside diameter 4·82 cm, depth 2·71 cm, outside width 8·05 cm, depth

On following pages: 230. Willow Flycatcher (*Empidonax traillii*); 231. Alder Flycatcher (*Empidonax alnorum*); 232. White-throated Flycatcher (*Empidonax albigularis*); 233. Least Flycatcher (*Empidonax minimus*); 234. Hammond's Flycatcher (*Empidonax hammondii*); 235. Grey Flycatcher (*Empidonax wrightii*); 236. Dusky Flycatcher (*Empidonax oberholseri*); 237. Pine Flycatcher (*Empidonax affinis*); 238. Pacific-slope Flycatcher (*Empidonax difficilis*); 239. Cordilleran Flycatcher (*Empidonax occidentalis*); 240. Yellowish Flycatcher (*Empidonax flavescens*); 241. Buff-breasted Flycatcher (*Empidonax fulvifrons*); 242. Black-capped Flycatcher (*Empidonax atriceps*).

4-41 cm, appears loose and unkempt, consists of fine strips of bark, grape (*Vitis*) tendrils, fine twigs, grass and herbs, bound together by spider or cankerworm (*Paleacrita vernata*) silk, streamers of oak and hickory catkins hanging below; primary building material hemlock twigs in Michigan, Spanish moss (*Tillandsia usneoides*) in much of S USA; placed 3-9 m up in fork of horizontal branch of small tree or shrub, often with leaf cover above and near water in ravine, sinkhole, forested swamp or near stream, tree species used include e.g. witch hazel (*Hamamelis virginiana*), various oaks (*Quercus alba*, *Q. nuttalli*, *Q. lyrata*), beech, hemlock, sugar maple, flowering dogwood, basswood (*Tilia americana*), elm (*Ulmus*), sugarberry (*Celtis laevigata*), possum haw (*Ilex deciduas*); nest occasionally reused in successive years. Clutch 1-4 eggs, most commonly 3; incubation period 13-15 days; fledging period 12-18 days. In Michigan 64% of nests fledge more than one young, elsewhere success lower; nests parasitized by Brown-headed Cowbird (*Molothrus ater*). Breeds after first year. Oldest reported individual 10 years 11 months.

Movements. Long-distance migrant, wintering in Central America and N South America. Leaves breeding grounds late Aug-Sept in N part of range, lingering to Oct in S; transient Aug to mid-Oct in Mexico, Sept to late Nov in Costa Rica, and rare Sept-Oct in Cuba and Bahamas; migrates S through breeding range, most following coast of Gulf of Mexico and Caribbean, as well as interior S of Isthmus of Tehuantepec (S Mexico) to Honduras; in addition, some migrate over Bahamas and Cuba to Yucatán Peninsula, and possibly from latter region over Caribbean to coasts of Venezuela and Colombia. Arrives on wintering grounds in Panama by Sept. Departure by mid-Apr in Panama, early Mar to mid-May in Costa Rica; transient in Mexico mid-Mar to May; arrival on breeding grounds first half of May. Vagrants reported in W North America and Canadian Maritime Provinces.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Overall population estimated at 4,700,000 individuals. Population relatively stable; US breeding-bird survey data show annual increase of 1·5% between 1966 and 1978, but annual decrease of 1·3% between 1978 and 1987. This species is often highly ranked for management and monitoring, because it appears sensitive to habitat fragmentation (in small fragments suffers high rates of nest predation and parasitism by cowbirds), and because of habitat loss and degradation on wintering grounds.

(1998a), Arendt (1992), Askins *et al.* (1990), Bennett (1980), Bent (1942), Blake & Loiselle (1992), Brauning (1992), Briskie (1994), Bull (1964), Chapa (1998), Clap *et al.* (1983), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), Fjeldså & Krabbe (1990), Finch (1991), Fitzpatrick (1978, 1980a), Freemark & Collins (1992), Garrido & Kirkconnell (2000), Hespenheide (1980), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Johnsgard (1979), Johnson (1963a), Kaufman (1996), Kellner & Ritchison (1988), Meyer de Schauensee & Phelps (1978), Miller (1963), Mumford (1964), Mumford & Keller (1984), Newman (1958), Oberholser (1974), Olendorf & Robinson (2000), Orejuela *et al.* (1980), Paynter (1995), Peck & James (1987, 1997), Peterjohn *et al.* (1995), Powell *et al.* (1992), Price *et al.* (1995), Pyle (1997b), Raffaele *et al.* (1998), Rappole *et al.* (1993), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Robinson, Thompson *et al.* (1995), Salaman (1994), Saunders (1909), Schorger (1927), Slud (1964), Sprunt & Chamberlain (1970), Stiles & Skutch (1989), Stoddard (1922), Stupka (1963),Udvardy (1963), Vidal-Rodríguez (1992), Wetmore (1972), Whitehead & Taylor (2002), Wiedenfeld *et al.* (1992), Wilson & Cooper (1998).

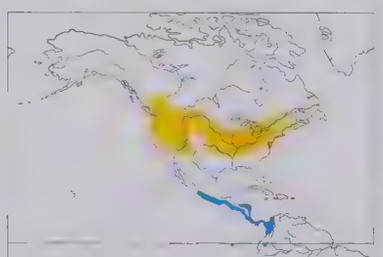
230. Willow Flycatcher

Empidonax traillii

French: Moucherolle des saules **German**: Weidenschnäppertyrann **Spanish**: Mosquero Saucero
Other common names: Traill's Flycatcher

Taxonomy. *Muscicapa traillii* Audubon, 1828, Arkansas River, USA.

Formerly considered conspecific with *E. alnorum*. Geographical variation in plumage, wing morphology and vocalizations probably clinal, becoming browner overall in W and paler in more arid environments, and racial boundaries not well defined; sometimes treated as monotypic. Described race *campestris* (from North Dakota, in N USA) synonymized with nominate. Four subspecies currently recognized.



Subspecies and Distribution.

E. t. adastus Oberholser, 1932 - breeds SW Canada (S British Columbia) S in USA to E California (E of Sierra Nevada) and in Great Basin and Rockies; winters probably mainly W Mexico S to Panama.

E. t. traillii (Audubon, 1828) - breeds S parts of Canada (Alberta, Saskatchewan, Ontario, Quebec) and NC & NE USA; winters SW Mexico S to Panama and possibly extreme NW Colombia, also rarely to NE Ecuador.

E. t. brewsteri Oberholser, 1918 - breeds extreme SW Canada (SW British Columbia) S, W of Cascades, to SW California (W of Sierra Nevada); winters probably mainly W Mexico S to Panama.

E. t. extimus A. R. Phillips, 1948 - breeds SW USA; presumably winters W Mexico.

Descriptive notes. 13·3-17 cm; 11·3-16·4 g. Nominate race has indistinct narrow pale loral area, whitish eyering; rest of head drab olive, slightly darker than upperparts; wings blackish, two whitish to pale yellow wingbars, whitish to pale yellow margins of secondaries and tertials (forming panel on secondaries of closed wing); tail dusky; throat and underparts pale greyish-white, contrasting dull brownish-olive wash across breast, darkest on side, pale yellow wash or tinge on belly and undertail-coverts; plumage varies with wear, in spring (fresh plumage) brightest green above, wingbars may be tipped buff, also wingbars, eyering and breastband most prominent, by late summer (worn) drabber and brownish-grey above, whiter below, wingbars and wing margins narrower and whiter; iris dark; bill moderately long, upper mandible black, lower mandible pale orange-yellow; legs blackish. Distinguished in field from extremely similar *E. alnorum* mainly by voice, also (with difficulty) by less greenish upperparts, less contrasting wingbars, slightly shorter tail and longer bill. Sexes similar. Immature is browner above, yellower below, broader yellowish-buff wingbars. Races vary mainly in plumage tone, browner in W: *brewsteri* is darkest, *adastus* intermediate, *extimus* palest. Voice. Common call a mellow upslurred "whuit", "whit" or "whik", by both sexes at all seasons. Song, mainly by male from highest available perch, rarely by female, a distinctive nasal and buzzy "fitz-bew", sometimes followed by "creet" note, also (male only) similar "fizz-bew"; "fitz-bew" song of *extimus* distinct from other races, described as having slow drawl on "bew" part. Dawn song in Mexico described as "spt'chew". Flight song consists of a rapid series of "wheet" notes, followed by 8-12 "creet" and "fitzbew". Also gives soft upslurred and then downslurred "whup" call, also "writ-tu", "wee-oo" or "zwee-oo" (similar to "whup" call with buzz added at end), these two sometimes combined as "writ-tu whup". Raspy "cree" begging call by older chicks. Bill-snapping during aggressive encounters.

Habitat. Breeds in variety of moist shrubby habitats, often near water: include wet to dry upland and lowland habitats with willow (*Salix*) and many other tree species in E of range, riparian vegetation in SW USA; beaver (*Castor*) meadows in W, as well as drier upland habitats of Palouse Prairie (SE Washington) of hawthorn (*Crataegus*), chokecherry (*Prunus*) or rose (*Rosa*) and dry ninebark (*Physocarpus*) thickets. Uses similar habitats during migration, especially willows in W USA. Winters in variety of habitats, including shrubby forest borders, open woodland, clearings, pastures and arid scrub, often near water; early-successional growth on river islands in Amazonia. Sea-level to 2500 m; on migration mostly below 1000 m, rarely above 3500 m (presumably to cross Andes).

Food and Feeding. Arthropods; occasionally fruit. Recorded items include bees and wasps (Hymenoptera, including Ichneumonidae), beetles (Coleoptera, including Coccinellidae), flies (Diptera, including Tabanidae), butterflies and moths (Lepidoptera), true bugs (Hemiptera), dragonflies and damselflies (Odonata); nestlings fed mainly with dipterans and hemipterans, also arachnids, orthopterans, isopods and molluscs recorded. Fruit consumption recorded in Sept, including blackberries and raspberries (*Rubus*), dogwood (*Cornus*); fruit also recorded in faeces in Costa Rica. Forages by searching for prey from low perch; frequently flicks tail downwards. Prey captured from the air or foliage, in aerial hawking and sally-glean manoeuvres; occasionally taken from ground.

Breeding. Late May to Jun. Nest-site selected by female; nest a woven cup of stems, bark shreds, dry grass, plant fibres and pine needles, lined with feathers, hair and rootlets, outside decorated with lichen, cocoons, shredded grass and cottony thistle (*Crisium*) fibres, sometimes streamers hanging from base (less commonly than nest of *E. alnorum*), average outside diameter 8·2 cm, height 6·7 cm, inside cup diameter 5·2 cm, depth 3·9 cm; placed 0·6-20 m (mostly 0·9-1·5 m) above ground in crotch of shrub or small tree, frequently willow (*Salix*), less often tamarisk (*Tamarix chinensis*), box elder (*Acer negundo*), on Pacific coast live oak (*Quercus agrifolia*), American elder (*Sambucus canadensis*), red-osier and grey dogwood (*Cornus stolonifera*, *C. racemosa*), hawthorn (*Crataegus*), buttonbush (*Cephalanthus*), alder (*Alnus*), pear (*Pyrus*), privet (*Ligustrum*), honeysuckle (*Lonicera*) or bracken fern (*Pteridium aquilinium*). Clutch 3-4 eggs; incubation period 13-14 days; fledging period 13-15 days. Success variable, 68·6% of nests fledged more than one young in Wisconsin USA, only 28% in British Columbia (Canada); average lifetime reproductive success for female 3·59 young; nests parasitized by Brown-headed Cowbird (*Molothrus ater*). Sexually mature in first breeding season after hatch year. Longevity record at least 11 years, but mean lifespan for male closer to 1 year.

Movements. Long-distance migrant; winters in S Mexico, Central America and N South America, rare S to NE Ecuador. Migrates at night. Departs breeding grounds mid-Aug to Sept; E populations swing W before heading S, avoiding SE USA in a circum-Gulf or trans-Gulf of Mexico route to Central and South America; rare in Cuba and Jamaica during autumn migration; C & W populations pass through Mexico Aug-Oct, and more abundant on Pacific slope than interior or Atlantic slope. Adults migrate earlier than juveniles, which may be stimulated to depart breeding grounds by declining insect resources. On return migration passes through Mexico Apr to early Jun; trans-Gulf route unlikely for E populations in spring. Arrives on breeding grounds late, May to early Jun.

Status and Conservation. Not globally threatened. Overall population estimated at 3,300,000 individuals; conservation plan aims at increasing total numbers by at least 50%. Fairly common to common. US survey data show annual decrease of 1·3% between 1966 and 1996, but significant increases in Maine, Maryland, New Jersey, New York, North Dakota and Pennsylvania. Nominate race has expanded its range in E USA and S Canada (Ontario) following forest removal, wetland drainage, and the overgrowing of pastures with shrubs and trees. SW race *extimus*, formerly common, declined dramatically over the last century because of destruction of its riparian habitats through water-flow regulation, agriculture and urbanization, and consequent cowbird parasitism, all of which factors affect other races too; now rare, or even locally extinct (e.g. in Arizona, California and N Arkansas), and has apparently disappeared from former range in NW Mexico (Baja California, N Sonora); currently numbers no more than c. 1000 individuals, with largest population (243 pairs in 1999) along R Gila, in SW New Mexico, and others containing fewer than 40 individuals each. Critical habitat for this race now protected in Arizona, California and New Mexico. Pacific coast race *brewsteri* has also declined; once common, it is now rare and local, with only c. 200 pairs left in California. Loss and alteration of wooded habitats in wintering range in Central America and N Colombia may also have a negative effect.

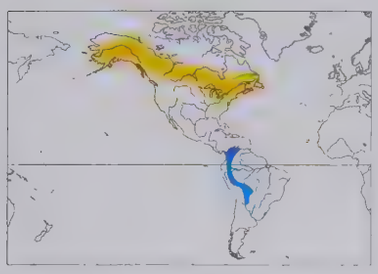
231. Alder Flycatcher

Empidonax alnorum



French: Moucherolle des aulnes **German**: Erlenschnäppertyrann **Spanish**: Mosquero Alisero

Taxonomy. *Empidonax traillii alnorum* Brewster, 1895, Upton, Maine, USA.

Formerly considered conspecific with *E. traillii*. Birds in NW of range (Alaska, Yukon Territory and NW Mackenzie) may average larger, with paler head and slightly paler back; named as race *alascensis*, but further studies required. Monotypic.

Distribution. Breeds from W Alaska S to SC British Columbia and E to Canadian Maritime Provinces, and from Great Lakes E in USA to New England and S to N Indiana, Ohio and, in Appalachians, to North Carolina. Winters mainly W South America, from C Colombia and E Ecuador S to E Peru and N & E Bolivia; probably also in E Panama and N Argentina.

Descriptive notes. 13-17 cm; 12-14 g. Has narrow indistinct pale lores and whitish eyering (rarely, lacking); rest of head drab olive, crown slightly darker than upperparts; wings blackish, two whitish to pale yellow wingbars, whitish to pale yellow margins of secondaries and tertials (forming panel on secondaries of closed wing); tail dusky; throat and underparts white, contrasting dull brownish-olive wash across breast, darkest on side, pale yellow wash or tinge on belly and undertail-coverts (especially in spring); plumage varies with wear, wingbars broader and sometimes tinged pale yellow, upperparts brightest green, wingbars, eyering and breastband most prominent in spring (fresh plumage), drabber olive above, whiter below and on wing margins, and wingbars and wing margins narrower in late summer (worn); iris dark; bill moderately long, upper mandible black, lower mandible pale orange-yellow; legs blackish. Distinguished in field with difficulty from *E. traillii* except by voice, but generally greener crown and upperparts, more pointed wings with

brighter and more contrasting wingbars, slightly shorter bill and longer tail. Sexes similar. Immature is browner above, broader yellowish-buff wingbars, sometimes buff wing-linings and thighs. Voice. Common call a short "pip", "pit", "tip", "bic", "peep" or "whit", perhaps more similar to call of *E. hammondii* than to that of *E. traillii*. Song a distinct buzzy "fee-béé-o", the "bee" accented, the "bee-o" slurred and dropping in pitch on "o". Also, a "wee-oo" call, similar to "pip" call but with buzzy ending and superficially resembling "fitz-bew" of *E. traillii*. Also "churr" and "kritter" calls recorded, perhaps constructed of series of "pip" calls or parts of other calls. Bill-snapping during aggressive encounters.

Habitat. Breeds in wet thickets and shrubby wetlands near forest. These habitats include alder-buckthorn (*Alnus-Rhamnus*) thickets in Michigan; successional stands 3-8 years old of maple (*Acer saccharum*, *A. ruber*) and birch (*Betula papyrifera*, *B. alleghaniensis*) in Nova Scotia; damp meadows open or overgrown with willow (*Salix*), alder, cedar (*Juniperus*), tamarack (*Larix laricina*), spruce (*Picea*), poplar (*Populus*), birch, hawthorn (*Crataegus*), elm (*Ulmus*), hazel (*Corylus*) and maple in Ontario; young deciduous trees and shrubs near water, including willow, alder, black cottonwood (*Populus trichocarpa*), rose (*Rosa*), honeysuckle (*Lonicera utahensis*), dogwood (*Cornus*), currant (*Ribes*), raspberry (*Rubus*) and aspen (*Populus tremuloides*) stands in British Columbia, with second growth 4-8 years old preferred; dogwood (*Cornus racemosa*), chokecherry (*Prunus virginiana*), red raspberry (*Rubus idaeus*), arrow wood (*Viburnum dentalum*), speckled alder (*Alnus incana*), apple (*Pyrus malus*) and other trees in New York. Uses variety of humid to semi-arid open habitats during migration, including scrubby fields, woodland, forest borders. Winters in lower strata of second growth, thickets and forest borders near water, also in early-successional vegetation on sandbars and in dense vegetation along oxbow lakes; near Iquitos, in Peru, recorded near standing water between shrubby vegetation of *Vermonia*, *Veruena* and *Clibadium* and open *Andropogon*, *Xyxis* and *Cyperus* grass with scattered palms. Breeds from sea-level to 1300 m; on migration to 2500 m in Mexico, rarely higher in Bolivia (Cochabamba) and Colombia (on Bogotá savanna); to 1100 in South America in winter.

Food and Feeding. Arthropods; also fruit in winter. Insects include hymenopterans, beetles (Coleoptera), flies (Diptera), lepidopterans, orthopterans. Searches for prey from perch 2·5-4·4 m up in trees and shrubs; frequently flicks or wags tail downwards. Prey captured from the air or foliage, by aerial hawking and sally-gleaning, relative proportions of foraging manoeuvres varying between different habitats; foraging flights last 4-6 seconds, after perching for 3-4 minutes.

Breeding. Mid-Jun to early Aug; short breeding season, 70-90 days. Nest built by female, a cup loosely constructed from various plant materials, many coarse streamers hanging beneath, lined with wiry grass and conifer needles; average outside diameter 8·2 cm, depth 6·25 cm, inside diameter 5·3 cm, depth 3·8 cm; placed on average 62·5 cm up (lower than *E. traillii*) in deciduous shrub or tree or in conifer, rarely in grass, most frequent nesting trees include willow, dogwood, beaked hazelnut (*Corylus cornuta*) and hawthorn. Clutch 3-4 eggs; incubation period 11-15 days, usually 14-15 days; fledging period probably 14 days. Nest parasitism by Brown-headed Cowbird (*Molothrus ater*) recorded. Longevity record 3 years 2 months.

Movements. Long-distance migrant, wintering almost exclusively in South America; more S winter distribution than *E. traillii*. Migrates at night. Departs breeding grounds late Aug, juveniles lingering longer than adults; migrates S through E & C USA, Atlantic slope of Mexico S to Veracruz (but not Yucatán Peninsula), interior and both slopes S from Chiapas, passing through Mexico and N Central America Aug-Sept, through Costa Rica late Aug to early Nov; rare in Florida, suggest that autumn migration may occur slightly E of spring migration. Probably leaves wintering grounds between Mar and early May; passing through Panama Apr to early May, Costa Rica and El Salvador up to late May, Central America and Mexico up to early Jun, and C & E USA early May to mid-Jun (peak in late May). Arrives on breeding grounds late and departs early; migration periods similar to those of *E. traillii*, perhaps on average 1 week later in spring and earlier in autumn; information on timing and routes hampered by problems associated with distinguishing the two species during migration. Vagrant recorded in Bermuda.

Status and Conservation. Not globally threatened. Common; total population estimated at 49,000,000 individuals. Densities 0·02-6 pairs/ha at various sites. Historical range contractions have been linked with expansion of *E. traillii*, especially in E USA, although validity of this link is questioned. Range expansion to S reported in interior mountains of SW Canada (SE British Columbia). May benefit during recovery from forest disturbance, as successional vegetation replaces cleared forest.

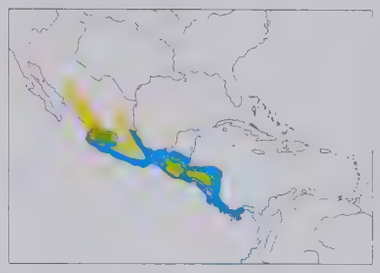
232. White-throated Flycatcher



Empidonax albigularis

French: Moucherolle à gorge blanche **Spanish**: Mosquero Gorgiblanco
German: Fahlkehl-Schnäppertyrann

Taxonomy. *Empidonax albigularis* P. L. Sclater and Salvin, 1859, Dueñas, Guatemala.
Three subspecies recognized.

Subspecies and Distribution.
E. a. timidus Nelson, 1900 - Pacific slope of W Mexico (extreme SE Sonora and SW Chihuahua S to Isthmus of Tehuantepec) and locally in interior (Guerrero and Oaxaca).
E. a. albigularis P. L. Sclater & Salvin, 1859 - Caribbean slope of E Mexico (S from SW Tamaulipas) S to Guatemala, El Salvador and Honduras; probably winters S to S Central America.
E. a. australis W. deW. Miller & Griscom, 1925 - Nicaragua S to Panama.

Descriptive notes. 12-14 cm; 12 g. Small brown *Empidonax* with short, rounded wings. Adult has pale lores and indistinct narrow buffy eyering; rest of head and back brown to grey-brown or brownish-olive, rump and uppertail-coverts more tawny-brown; wings and tail dusky, two dull brown to pale buff wingbars, pale cinnamon to pale yellow margins of secondaries and tertials

(forming panel on secondaries of closed wing); throat white, white extending under auriculars; breast washed grey-brown, belly and undertail-coverts pale yellow, buffier on flanks; in worn plumage, greyer above, paler below, wingbars and margins of remiges narrower and whitish; iris dark; bill relatively long and broad, upper mandible black, lower mandible pinkish-orange; mouth-lining orange; legs blackish. Differs from similar *E. traillii* and *E. alnorum* in warmer brown upperparts, more cinnamon-buff wingbars, ochre-washed flanks. Sexes alike. Juvenile is duller, more sooty brown above, broader and brighter cinnamon wingbars. Races differ minimally in plumage tone. Voice. Burry and nasal call notes with rising inflection, as "neeark" or "rreeah" (Mexico) or "wrick", "rrrip" and "pit-a-rip" (Costa Rica). Song described as a louder "bee-uh" (Mexico) and "wheet", "whirrt" or doubled "whit-whirrt" (Costa Rica).

Habitat. Breeds in damp meadows and other open to semi-open shrubby second-growth habitats, often near water. Winters in marshes with tall reeds and scrubby margins. At 1200-3000; down to sea-level during winter.

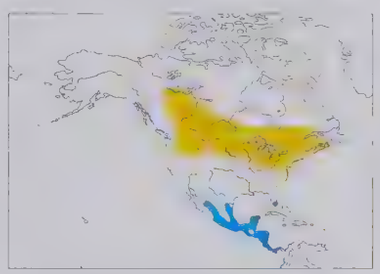
Food and Feeding. Mainly insects, including beetles (Coleoptera), small wasps (Hymenoptera), larvae and nymphs of mantids and grasshoppers (Orthoptera), damselflies (Zygoptera), homopteran bugs, and flies (Diptera); also small amounts of fruit. Sits upright on low perch 1-2 m above ground; sallies out to capture prey from the air or vegetation; flicks wings and tail upon landing.

Breeding. Apr-Sept in Mexico and Apr-Jun/Jul in Costa Rica. Nest a cup made of dry grass and other plant fibres, placed 1-2 m up in shrub or small tree. Clutch 2-3 eggs, usually 2 in Costa Rica; no other information.

Movements. Little known. Winter visitor to W Mexico (Sinaloa) Aug to early May; Mexican migrants thought to reach Costa Rica.

Status and Conservation. Not globally threatened. Uncommon to common, but local. Fairly common to common non-breeding visitor in Sinaloa, less common in interior and on Atlantic slope of Mexico and S Yucatán Peninsula. Occurs in Lamanai Archaeological Reserve, in Belize, and Río Negro Jaguar Reserve and Rancho Naturalista, in Costa Rica.

Bibliography. Anon. (1998a), Binford (1989), Blake, E.R. (1953, 1958), Cory & Hellmayr (1927), Dearborn (1907), DeGraaf & Rappole (1995), Howell & Webb (1995a), Fitzpatrick (1980a), Land (1970), Lee Jones (2004), Lowery & Dalquest (1951), Monroe (1968), Ridgely & Gwynne (1989), Ridgway (1907), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Wetmore (1943, 1972), Winker *et al.* (1999).



233. Least Flycatcher

Empidonax minimus

French: Moucherolle tchébec **German**: Zwergschnäppertyrann **Spanish**: Mosquero Mínimo

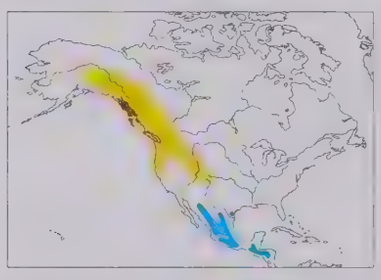
Taxonomy. *Tyrannula minima* W. M. Baird and S. F. Baird, 1843, near Carlisle, Pennsylvania, USA.
Probably diverged from other members of genus c. 1·8 million years ago, in late Pliocene or early Pleistocene. Monotypic.

Distribution. C Canada (S Yukon and NW interior E to S Quebec and S Maritime Provinces) S in USA to NE Colorado, N Great Plains, New England and (in Appalachians) NW Georgia. Winters both slopes of Mexico (S from Sonora and Tamaulipas), rarely S USA, S through Central America, at least casually to Costa Rica and C Panama.

Descriptive notes. 12·5-14 cm; 8-13 g. Small, compact *Empidonax* with short bill, short rounded wings and short, narrow tail. Has whitish supraloral stripe and bold white eyering; crown rounded, brownish to greyish-olive; ear-coverts, malar region, nape and upperparts greyish-olive; wings dusky, two broad white to pale yellow wingbars, white to pale yellow margins of tertials and secondaries (forming panel on secondaries of closed wing); tail slightly notched, dusky; throat whitish, underparts whitish, greyish wash across breast and sides, belly and undertail-coverts tinged pale yellow; plumage varies with wear, brightest above and with broadest wingbars and margins on remiges in spring (fresh plumage), drabber overall with narrower and whiter wingbars and remex margins in Sept-Dec (worn); iris dark; bill triangular, upper mandible black, lower mandible dusky with yellow-orange base; legs blackish. Distinguished from congeners mainly by small size, short primary extension, colour; from similar *E. hammondii* also by wider bill with paler lower mandible, bolder white primary and secondary edgings. Sexes similar, female distinguished in hand by shorter length of flattened wing. Juvenile resembles fresh-plumaged adult, but browner above, whiter below, wingbars tinged buff. Voice. Most frequent call a short soft "whit". Most distinctive vocalization "chebec", by both sexes. Dawn singing starts 45-71 minutes before sunrise, lasts 30-70 minutes; flight song given 20-60 minutes after sunset, begins with sporadic "weep" notes while hopping in tree, then combined with "chebec" and other notes in flight, described as "chebec-tooral-ooral, chebec-tooral-ooral". Quiet "churr" or "thrr thrr" calls by both sexes during nest-building or sitting on nest; other twitter, chatter and trilled notes and guttural "speets" call reported when mates greet each other or young. "Wee-weep" notes during aggressive encounters and nest or territorial defence. Bill-snapping during aggressive encounters. Recent work suggests possible differences in song structure between sexes.

Habitat. Breeds in mature deciduous and mixed forests, secondary forest, forest clearings and borders, and occasionally shrubby fields; associated with closed canopy forest of sugar maple (*Acer saccharum*) in SE Canada (Quebec). Similar habitats used during migration. Winters in tropical forest near openings and edges, old and young second growth, dense thickets, brushland and pastures; sea-level to 1000 m on Pacific slope of Central America, to 1500 m on Caribbean slope.

Food and Feeding. Insects, occasionally fruit. Diet includes hymenopterans, beetles (Coleoptera), flies (Diptera), lepidopteran adults and larvae, orthopterans, arachnids, damselflies and dragonflies (Odonata), mayflies (Ephemeroptera); midges (Chironomidae) commonest item in stomachs of birds at Delta Marsh, in Manitoba (C Canada); fruits and seeds found in stomachs include those of *Rubus*, *Sambucus canadensis*, *Phleum pratensis* and *Chaetochloa*. Forages by searching from



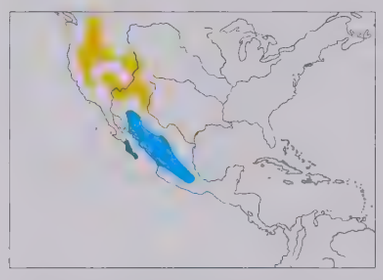
low perch; perches erect, often with tail held slightly below plane of body; flicks tail. Captures prey from air or foliage, using aerial sallies and hover-glean manoeuvres.
Breeding. Late May to early Aug; short breeding season estimated at no more than 64 days. Nest cup neat and compact, with thick rim, woven with bark strips, downy plant fibres, grass, twigs, rootlets, moss, pine (*Pinus*) needles, leaves and other materials, lined with fine grass, feathers, animal hair, thistle or willow (*Salix*) down, and plant stems; in various studies average outside diameter 6·5-8 cm, outside depth 3·6-10 cm, inside diameter 4-5 cm, depth 2·5-3·5 cm; placed 0·6-15 m up in crotch or fork (with 3-4 branches) of small tree, e.g. birch (*Betula*) maple (*Acer*), poplar (*Populus*), pine, American beech (*Fagus*), willow, green ash (*Fraxinus pennsylvanica*), elderberry (*Sambucus*), cherry (*Prunus*) or oak (*Quercus*), nest tree selected in proportion to abundance at some sites. Clutch 4 eggs; incubation period 13-15 days; fledging period 12-17 days. Success variable, 38% of nests fledge more than one young in Manitoba (Delta Marsh), 51·9% in Michigan, 53% in Quebec, perhaps higher elsewhere; nests infrequently parasitized by Brown-headed Cowbird (*Molothrus ater*). Sexually mature in first breeding season after hatching. Longevity record 5 years 11 months after ringing.
Movements. Long-distance migrant, wintering in Mexico and Central America. Migrates at night. Departs breeding areas relatively early, in Jul to mid-Aug, adults leave earlier than juveniles (perhaps because of strong competition for winter territories); migrates on average 15 days ahead of *E. alnorum*, *E. traillii* and *E. flaviventris*; moves through SC USA from Mississippi Valley and N Gulf states W to Rocky Mts, passing through most of Mexico (both slopes, avoiding NW) mid-Jul to Oct, arriving in Guatemala by mid-Aug and El Salvador by early Sept; autumn migration estimated to take 25 days, and an individual recovered in Chiapas (Mexico) 32 days after ringing at Long Point (S Canada) suggests minimum average daily flight of 98-116 km (depending on migration route). Departs wintering grounds Apr-May, passing through S USA late Mar to mid-Apr, arriving in S Canada first half of May and N Canada by late May; males arrive on breeding grounds c. 6 days earlier than females. Casual N of breeding range.
Status and Conservation. Not globally threatened. Common; overall population estimated at 14,000,000 individuals. Breeding density varies, 1·4 pairs/ha in New Hampshire (USA) to greater than 4·4 pairs/ha in Manitoba (Canada); perhaps higher densities achieved on wintering grounds. Breeding population for Canadian Maritime Provinces estimated at 77,000 individuals. Survey data for 1966-1991 indicate no significant population trends on a continental scale, although regional declines noted in E North America and increases in C & W North America. E declines may be due to progressing succession and maturity of forests, but also correlated with forest die-back due to acid rain in Quebec. N populations may also fluctuate with spruce-budworm outbreaks, by feeding on the abundant adult moths. Loss and alteration of wooded habitats in wintering range may also have a negative effect (e.g. Mexican high-elevation forests have been extensively logged and overgrazed).
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Beal (1912), Bent (1942), Binford (1989), Breckenridge (1956), Briskie (1994), Briskie & Sealy (1989a, 1989b), Briskie *et al.* (1990), Campbell *et al.* (1997), Cory & Hellmayr (1927), Cyr & Larivée (1995), Darveau, DesGranges & Gauthier (1992), Darveau, Gauthier *et al.* (1993), Davis (1959), DeGraaf & Rappole (1995), Delgado (1985), Della Sala & Rabe (1987), Ely (1970), Erskine (1992), Fitzpatrick (1980a), Greenberg (1992), Hespenheide (1971a), Holmes & Robinson (1981), Holmes & Sherry (1988), Holmes *et al.* (1986), Howell & Webb (1995a), Hussell (1981, 1984), Hussell *et al.* (1992), Johnsgard (1979), Johnson (1963a), Kasumovic *et al.* (2003), Kaufman (1996, 1997), de Kiriline (1948), MacKenzie *et al.* (1982), MacQueen (1950), Martin (1994), Monroe (1968), Nice & Collias (1961), Peck & James (1987, 1997), Perry & Andersen (2003), Peterjohn *et al.* (1995), Phillips & Lanyon (1970), Price *et al.* (1995), Pyle (1997b), Ramos (1988), Rappole & Warner (1980), Ridgely & Gwynne (1989), Ridgway (1907), Sealy & Biermann (1983), Sherry (1979), Sibley (2000), Slud (1964), Small (1994), Stiles & Skutch (1989), Tarof & Ratcliffe (2000), Thompson (1891), Udvardy (1963), Wagner (1998), Wetmore (1972), Wiedenfeld *et al.* (1992), Witham & Hunter (1992), Zink & Johnson (1984).

234. Hammond's Flycatcher

Empidonax hammondii

French: Moucherolle de Hammond **Spanish**: Mosquero de Hammond **German**: Tannenschnäppertyrann

Taxonomy. *Tyrannula hammondii* Xántus de Vesey, 1858, Fort Tejon, California, USA.
Monotypic.
Distribution. Breeds from C Alaska and W Canada (from S Yukon) S in W USA to EC California, EC Nevada, C Utah and the Four Corners Region E to NC New Mexico. Winters locally SW USA and S from Mexico (Pacific slope and interior highlands) to Guatemala, El Salvador, Honduras and probably NC Nicaragua.



Descriptive notes. 12·5-14·5 cm; 7·7-12·1 g. Has white eyering, broadest at rear (forming slight teardrop shape); greyish crown, slight rounded crest; head side and nape grey, upperparts greyish-olive; wings dusky, two narrow white wingbars, indistinct narrow white margins of secondaries and tertials; long primary projection; tail short and narrow, tip notched, dusky, white outer webs of outer rectrices; throat pale grey, breast whitish, greyish-olive wash across chest, sides and flanks (creating vested appearance), lower belly and undertail-coverts whitish with pale yellow wash; plumage brighter when fresh (moults before migrating to wintering grounds), with dark olive breast and back contrasting grey head, brighter yellow below, wingbars and tertial margins tinged pale buffy yellow, becomes duller and paler with wear; iris dark; bill small, short and narrow, upper mandible black, lower mandible dark with yellowish-orange base; legs blackish. Best distinguished from similar *E. oberholseri* by voice, also habitat, and shorter and thinner bill, longer primary projection, more compact rounded body, more forked tail, slightly shorter tarsus. Sexes similar. Juvenile resembles adult, but broader and buffier wingbars, brighter olive back. Voice. Common call a distinct and sharp "pip", "peep" or "peek", reminiscent of that of Pygmy Nuthatch (*Sitta pygmaea*). Song consists of three elements, "tsi-pik", a high and then scratchy "swi-vrk" and lower "grr-vik"; distinguished from that of *E. oberholseri* by lower pitch, hoarser quality, lack of clear high notes, more strongly syllabled. Also a unique soft whistle, "k-lear", often followed by slightly buzzy "whee-zee", most often by male irregularly during breeding season; also "d-d-d-d-d-d-drrt" twittering trill, similar to trill of *E. oberholseri* but higher, by both sexes. Female gives "wheep" position note. Older nestling give raspy "du-wee" begging call. Bill-snapping during aggressive encounters.
Habitat. Breeds in cool mature coniferous and mixed forests, including Douglas Fir (*Pseudotsuga menziesii*), ponderosa and lodgepole pines (*Pinus ponderosa*, *P. contorta*), spruce (*Picea*), aspen (*Populus*), alder (*Alnus*) and dogwood (*Cornus*). Wider variety of habitats during migration, including deciduous and coniferous forest, pine-oak (*Pinus-Quercus*) woodlands, willow (*Salix*) thickets, chaparral, and scrub. Winter habitats similar to breeding ones, including fir, pine, oak and riparian forests in cool highlands of Mexico and Central America. Found at 2100-3000 m in Colorado (USA); 1000-2600 m in El Salvador. Usually found higher in tall coniferous forest; *E. oberholseri* lower in chaparral and small trees, and *E. wrightii* in sagebrush (*Artemisia*) and more arid habitats.
Food and Feeding. Insects, including adult and larval lepidopterans, coleopterans (of family Scarabaeidae), Diptera (of families Empididae, Rhagonidae, Syrphidae, Tipulidae), homopteran bugs (Cicadellidae), braconid wasps. Searches for prey while perched on small dead branches and twigs, from ground level to middle canopy 30 m up in shaded open areas; perches less upright than congeners, often flicks tail. Captures prey in flight, using sally and hover-glean manoeuvres directed to air, foliage, bark, branches or ground; prey sometimes beaten or crushed against perch to remove wings or otherwise to prepare for consumption. Forages more frequently on leaf surfaces at higher levels within canopy early in breeding season, switching to more aerial prey at lower levels later in season.
Breeding. Late May to Aug. Nest built by female, a compact cup made of fine plant fibres, fine grass, bark strips, rootlets, lichen and leaves, lined with feathers of other birds, bud scales, animal hair, fine grass, beard lichen (*Usnea*), cottony plant fibres, one in California constructed mostly of lichen, moss and bryophytes and bound with spiderweb; average outside diameter 8·5 cm, height 5·4 cm, inside diameter 5·7 cm, depth 2·5 cm; placed 3·5-15 m up, saddled on large horizontal tree limb where small branches emerge, less frequently in crotch of tree trunk, nest trees include various conifers, *Populus*, birch (*Betula*), maple (*Acer*). Clutch 3-4 eggs, 4 more frequent; incubation period 15 days; fledging period 16-18 days. Nest parasitism by Brown-headed Cowbird (*Molothrus ater*) occurs infrequently.
Movements. Migrant, wintering in Mexico and Central America. Migrates at night. Autumn migration protracted compared with close congeners; departs breeding grounds mid-Aug to Sept, lingers in S California to mid-Oct, passes through Arizona mid-Aug to early Nov, arrives in Guatemala mid-Oct; moves S along Sierra Nevada before crossing Pacific slope and SW deserts, using middle elevations in Arizona; travels through Mexico S along Sierra Madre, then spreads out over S & E Central Plateau (avoiding coastal plain of S Sonora and Sinaloa); passage earlier and lasts 5 weeks in interior, c. 7 weeks in coastal areas. Departs wintering grounds Mar-May, passing through S Arizona late Mar to late May and far W USA mid-Mar to early Jun; adult males arrive on breeding grounds first, followed by first-year males, then adult females and, last, first-year females. In general, migrates earlier in spring and later in autumn than *E. oberholseri*. Casual N of breeding range; vagrants recorded along Gulf Coast of USA and in E North America, usually in autumn.
Status and Conservation. Not globally threatened. Common; overall population estimated at 13,000,000 individuals. Densities 14-47 birds/km², varying within and between habitats. Survey data show trend of non-significant increase between 1966 and 1991, 1·3% annually (especially in Alberta, California and Colorado). This species' preferred habitat of old-growth forest greater than 10 ha in size, and 80-90 years of age, is threatened with reduction and fragmentation by logging. Loss and alteration of wooded habitats in wintering range may also have a negative effect (e.g. Mexican high-elevation forests have been extensively logged and overgrazed).

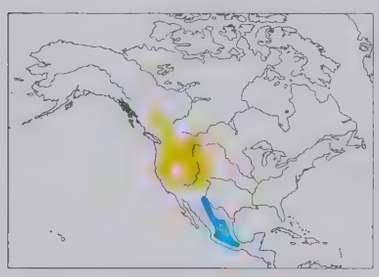
235. Grey Flycatcher

Empidonax wrightii

French: Moucherolle gris **German**: Trockenbusch-Schnäppertyrann **Spanish**: Mosquero Gris
Other common names: Wright's Flycatcher

Taxonomy. *Empidonax wrightii* S. F. Baird, 1858, El Paso, Texas, USA.
Formerly considered conspecific with *E. oberholseri*. Despite many similarities with that species, is apparently more closely related to *E. hammondii* and *E. atriceps*. Monotypic.
Distribution. Breeds extreme SW Canada (S British Columbia) and Great Basin states of NW USA S to SC California and E to S Wyoming and C Colorado, locally to W Texas. Winters SW USA and Mexico (S to S Baja California and Oaxaca).

Descriptive notes. 14-15·5 cm; 12·5 g. Large pale grey *Empidonax*. Has narrow whitish supraloral stripes meeting over bill, narrow whitish eye-ring; crown dull pale grey, slight rounded crest; head side, nape and upperparts grey; wings blackish-grey, two narrow whitish wingbars, narrow pale grey margins of secondaries and tertials; short primary projection; tail long, narrow, slightly notched, grey, outer webs of outer rectrices white; throat whitish-grey, breast pale grey, sometimes slightly darker breastband, lower belly and undertail-coverts whiter with faint yellow wash; plumage varies with wear, has slight olive tinge above, broader yellowish-white wingbars and pale yellow wash on belly and undertail-coverts when fresh (most moult on wintering grounds), becomes whiter below, paler grey above and with wing markings and outer webs of outer rectrices whiter and narrower when worn; iris dark; bill long and narrow, upper mandible black, lower mandible pinkish-yellow with sharply defined black tip; legs blackish. Sexes alike. Juvenile is similar to adult, but brownish-grey above, tinged brownish-buff below, pale buff wingbars and margins of tertials. Distinguished from congeners mainly by long wings and bill, uniformly pale greyish upperparts, pale band above bill, bill pattern. Voice. Frequent call a dry "pit" or "whit". Song, by male only, consists of two elements, a "chuwip", "chi-bit" or "jr-vrip" and a higher "teeap", "whilp" or "tidoo", given in various combinations as e.g. "sprlat-sprlat", "chlup-clup", "chuh-lup-chu-lup", "sprlat-prit" or "sprlat-seep". Dawn song similar. Both sexes give rattle call, "pddrea" or "pddreap", during aggressive encounters, territorial disputes and chases, both also give "d-d-d-d-d" or "dit-dit-dit-dit-dit" solicitation call during greeting near nest or in display, male solicitation call from perch 1·5-6 m high; rattle and solicitation calls sometimes combined into "whea, whea, pddrt, pddrt, whea, whea, pdrrt" phrases. Flight song, given while flying in wide circle 15-30 m up, described as "whit-whit-whit-whit-whit-weak-wheat-wheat-stiddle-d-doo-stiddle-d-doo". Bill-snapping during aggressive encounters and aerial foraging.



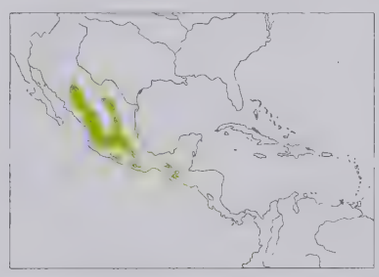
Habitat. Breeds in arid woodlands and shrublands, typically large sagebrush (*Artemisia*), often mixed with antelope brush (*Purshia*), rabbitbrush (*Chrysothamnus*), mountain mahogany (*Cercocarpus ledifolius*), piñon pine (*Pinus edulis*), juniper (*Juniperus*) or ponderosa pine (*Pinus ponderosa*); mature open forest of ponderosa pine, white fir (*Abies concolor*) and incense cedar (*Calocedrus decurrens*) with sagebrush understorey and in Jeffrey pine (*Pinus jeffreyi*) forest with shrub understorey in NE California; open woodland of ponderosa pine, Gary oak (*Quercus garryana*) and Douglas fir (*Pseudotsuga taxifolia*) with bare understorey in Washington. During migration, also riparian willow (*Salix*) thickets and brushy fields in NW California, arid chaparral with oaks and grey pine (*Pinus sabiniana*) in foothills of W Sierra Nevada, and riparian oases, mesquite (*Prosopis*) and low oaks (*Quercus*) through the Great Basin and Mojave, Sonoran and Chihuahuan Deserts. Winters in arid open to semi-open scrub, woodland, thorn-forest, riparian woodland and mesquite. Winters from sea-level to 2500 m in W Mexico, usually below 2200 m in Arizona. *E. hammondii* usually found higher in tall coniferous forest, and *E. oberholseri* lower in chaparral and small trees.
Food and Feeding. Insects; possibly some fruit in winter. Searches for prey while perched on lowest branches of large conifers, or on dead branch or top of large bush or shrub; perches upright, slowly dips tail downwards in distinctive motion. Captures prey in flight, using sally manoeuvres directed to air, foliage, bark, branches or ground.
Breeding. Late May to mid-Aug; double brooded. Nest cup constructed of grass, pine needles, bark shreds and sage panicles, lined with soft grass, feathers and animal hair, average outside diameter 12·1 cm, height 6·1 cm, inside diameter 6·8 cm, depth 4·6 cm, more flat and coarse than nest of *E. oberholseri*; placed in fork low in bush or shrub or on top of large branches, average 5·4 m up in California (Black Mt), 0·6-3·4 m up in N Arizona, plants include pines, juniper, Douglas fir, bitterbrush (*Purshia tridentate*) and sagebrush. Clutch 3-4 eggs; incubation period 14-15 days; fledging period c. 16 days. Of 16 nests in NE California, seven successfully fledged more than more young. Sexually mature in first breeding season after hatching.
Movements. Short-distance to medium-distance migrant, wintering mostly in Mexico. Migrates at night. Departs breeding grounds early, from Aug to mid-Sept, migrating W of Cascades and Sierra Nevada, arriving on wintering grounds Aug-Sept. N return through Great Basin, E of Cascades and Sierra Nevada and through SW USA, reaching breeding grounds mid-Apr to late May, males generally arriving c. 1 week before females. Migration periods last c. 7 weeks. Vagrant in E North America, usually in autumn or winter.
Status and Conservation. Not globally threatened. Common, increasing; overall numbers estimated at 1,200,000 birds. Reported densities of 10-30 singing males/km². Estimated 167,000 breeding pairs in Colorado, representing 10-19% of total population. Survey data indicate rangewide population increase of 11·6% annually between 1966 and 1995; range expanded 320 km N through C Washington into British Columbia (Okanagan Valley) during 1970-1987, and recent range expansions also reported in SW California. Some local populations eliminated by clear-cutting of conifer woods for cattle pasture and mining operations. Fragmentation of forest may also lead to increase in Brown-headed Cowbird (*Molothrus ater*) numbers and consequent increase in nest parasitism.
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bent (1942), Binford (1989), Campbell *et al.* (1997), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), Finch (1991), Fitzpatrick (1980a), Gaines (1992), Grinnell & Miller (1944), Harris (1996), Hejl *et al.* (1995), Hoffman (1927), Howell & Webb (1995a), Hutto (1992), Johnson (1963a), Kaufman (1996), Lavers (1975), Peterjohn *et al.* (1995), Price *et al.* (1995), Pyle (1997b), Ridgway (1907), Root (1988), Russell, H.N. & Woodbury (1941), Russell, S.M. & Monson (1998), Sauer & Droege (1992), Sedgwick (1998b), Sibley (2000), Small (1994), Sternling (1999), Udvardy (1963), Whitney & Kaufman (1986), Yaich & Larrison (1973).

236. **Dusky Flycatcher**

Empidonax oberholseri

French: Moucherolle sombre **German**: Buschland-Schnäppertyrann **Spanish**: Mosquero Oscuro

Taxonomy. *Empidonax oberholseri* A. R. Phillips, 1939, Hart Prairie, San Francisco Mountain, Arizona, USA.
Formerly considered conspecific with *E. wrightii*, although appears not to be closely related. Monotypic.
Distribution. Breeds W Canada (N British Columbia E to SW Saskatchewan) S in W USA (mainly W of Rocky Mts) to S California and NE New Mexico. Winters SW USA (E to W Texas) and Mexico (S, mainly in highlands, to Oaxaca).



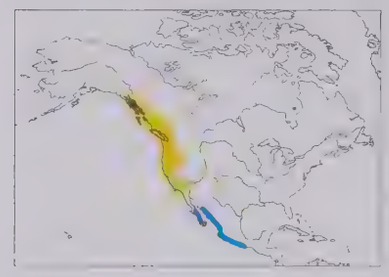
Descriptive notes. 13-15·2 cm; 9·3-11·4 g. Has bold white eyering and supraloral line; greyish-olive crown, slight rounded crest; head side, nape and upperparts greyish-olive; wings dusky, two narrow white wingbars, indistinct narrow white margins of secondaries and tertials; short primary projection; tail of medium length, narrow, tip square or notched, dusky with white outer webs of outer rectrices; throat whitish to pale grey, breast whitish with pale olive-grey wash across chest, lower belly and undertail-coverts washed pale yellow; plumage varies with wear (moults after migrating to wintering grounds), brighter with browner crown and upperparts and brighter yellow below in fresh plumage, becomes duller and paler with wear; iris dark; bill small and narrow, upper mandible black, lower mandible dark with yellowish-orange at base; legs blackish. Best distinguished from similar *E. hammondii* by voice, also habitat, and by longer bill, more conspicuous eyering and lores, shorter primary projection, more rounded tail, slightly longer tarsus, also by timing of moult; from *E. wrightii* by shorter bill, wing morphology, slightly darker upperparts, bill pattern. Sexes similar. Juvenile resembles adult, but broader and buffier wingbars, brighter and browner upperparts, more extensive orange-yellow on lower mandible. Voice. Common call a dry "whit". Song consists of three elements, a rising "prll-it" or "sibip", a clear lower "prrdrrt" or "quwerrrp" and a high "pseet" or "psuweet", given in any combination, sometimes with twittering note added in, e.g. as "prll-it" or "prll-it pseet orprll-it, prrdrrt, prrll-it pseet" or "prrll-it, d-d-d-d". Twittering solicitation call "d-d-d-d", frequently combined with "prll-it" song. Flight song described as "whit-whit-whit-whit whit-week-wheak-wheak-wheak-buzeek-buzeek-buzeek-stiddle-d-doo-stiddle-d-doo-stiddle-d-doo". Also unique "du-hic" or "dee-hic" call throughout breeding season (more frequently from pair-formation to incubation), early and late in day; also a "bdrrt" rattle call. Loud high "wheak" or "whee-o" during aggressive encounters, chases, copulation and during flight song. Bill-snapping during aggressive encounters.
Habitat. Breeds in open coniferous forest, mountain chaparral, aspen (*Populus*) groves, willow (*Salix*) thickets, open brushy areas and scrub, often on mountainsides; pine forest with dense understorey of saplings or mixed coniferous forest with chaparral understorey of *Arctostaphylos*, *Ceanothus*, *Ribes*, *Prunus*, *Cercocarpus* or *Abies* in California; mixed forest with ponderosa pine (*Pinus ponderosa*) and Douglas fir (*Pseudotsuga menziesii*) and shrubby clearings in W Montana. Requirements similar but less restricted during migration, preferring shady broadleaf vegetation. Winter habitats similar to breeding ones, also arid to semi-arid scrub, oak (*Quercus*) scrub, shrubby clearings, riparian and woodland edges, and pine-oak woodlands. Breeds at 650-2300 m in Canada (British Columbia); 1000-3000 m in non-breeding range in Mexico, lower (to sea-level) during migration. *E. hammondii* usually found higher in tall coniferous forest, and *E. wrightii* in sagebrush (*Artemisia*) and more arid habitats.
Food and Feeding. Insects, including adult and larval lepidopterans, dipterans, hymenopterans, orthopterans, and Odonata. Searches for prey while perched on small dead branches and twigs; perches upright, often jerks tail up. Captures prey in flight, using sally and hover-glean manoeuvres directed to air, foliage, bark, branches or occasionally the ground; items sometimes shaken, beaten or crushed against perch to remove wings or otherwise to prepare them for consumption.
Breeding. Late May to Aug. Nest built by female, neatly woven cup made of grass and finely shredded plant materials, lined with fine weed bark, grass, animal hair, vegetable down, feathers, bud scales, beard lichen (*Usnea*) and pine needles, average outside diameter 7·4 cm, height 7·2 cm, inside diameter 5·3 cm, depth 3·6 cm; placed in upright crotch on average 2 m up in tree or bush, including willow (*Salix*), alder (*Alnus*), chokecherry (*Prunus virginiana*), Rocky Mountain maple (*Acer glabrum*), mallow ninebark (*Physocarpus malvaceus*), aspen (*Populus tremuloides*), sagebrush (*Artemisia*) and Rocky Mountain juniper (*Juniperus scopulorum*). Clutch 4 eggs; if first clutch nest lost, renesting clutch 2-4 eggs; incubation period 15-16 days; fledging period 17-18 days. Nesting success 40% in W Montana; occasionally parasitized by Brown-headed Cowbird (*Molothrus ater*). Breeds at 1 year of age. Longevity record 8 years.
Movements. Migrant, wintering SW USA and Mexico. Departs breeding grounds Aug, passing through Mexico Aug-Sept; leaves wintering grounds Apr-May, migrating through mountains of Arizona to arrive on breeding grounds late Apr-May, males typically 1 week before females. Vagrant in E North America.
Status and Conservation. Not globally threatened. Common; overall numbers estimated at 3,600,000 birds. Survey data show population increase of on average 3·6% annually between 1966 and 1991 in USA, although no significant trend across North America. Probably benefits from increase in shrubby habitat following thinning of dense coniferous forests. Populations inhabiting willow thickets and other riparian areas perhaps vulnerable to habitat degradation through water-management programmes, livestock grazing and other human activities. Loss and alteration of wooded habitats in wintering range may also have a negative effect (e.g. Mexican high-elevation forests have been extensively logged and overgrazed).
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Beaver & Baldwin (1975), Bent (1942), Campbell *et al.* (1997), DeGraaf & Rappole (1995), Eckhardt (1977), Edwards (1972), Finch (1991), Fitzpatrick (1980a), Howell & Webb (1995a), Johnsgard (1979), Johnson (1963a), Kaufman (1996), Hejl *et al.* (1995), Lein (2002), Liebezeit & George (2002), Pereyra & Morton (2001), Peterjohn *et al.* (1995), Phillips *et al.* (1964), Price *et al.* (1995), Pyle (1997b), Pyle *et al.* (1987), Root (1988), Sedgwick (1975, 1993a, 1993b), Sibley (2000), Small (1994), Udvardy (1963).

237. **Pine Flycatcher**

Empidonax affinis

French: Moucherolle des pins **Spanish**: Mosquero de los Pinos
German: Kiefernschnäppertyrann

Taxonomy. *Tyrannula affinis* Swainson, 1827, Temascaltepec, Mexico.
Vocal differences between populations N & S of Isthmus of Tehuantepec suggest to some that more than one species may be involved. Five subspecies recognized.
Subspecies and Distribution.
E. a. pulverius Brewster, 1889 - NW Mexico, from Sonora and Chihuahua S to Jalisco.
E. a. trepidus Nelson, 1901 - NE Mexico (Coahuila, Tamaulipas); winters S to S Mexico (Chiapas) and Guatemala.
E. a. affinis (Swainson, 1827) - S Mexican Plateau (Michoacán S to Puebla).
E. a. vigensis A. R. Phillips, 1942 - Veracruz, in SE Mexico.
E. a. bairdi P. L. Sclater, 1858 - S Mexico (Guerrero and Oaxaca, possibly Chiapas), possibly also W Guatemala.



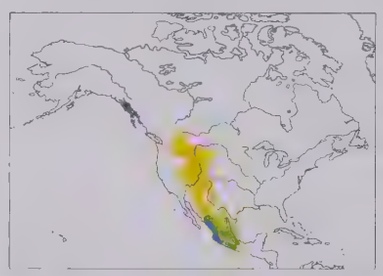
Descriptive notes. 13-14·5 cm; 11·5 g. Nominate race has pale greyish lores, whitish teardrop-shaped eye-ring extending to point behind eye; crown olive to greyish-olive; head side, nape and upperparts olive to greyish-olive; wings dusky, whitish to buff wingbars, pale yellow edges of secondaries and tertials (forming panel on secondaries of closed wing); tail dusky; throat pale greyish-yellow, underparts pale yellow, grey or greyish-olive wash across chest; iris dark; bill relatively narrow, upper mandible black, lower mandible orange-yellow; legs blackish. Differs from *E. difficilis* in generally narrower bill, also generally slimmer and longer-winged, with less contrasting wingbars, thicker eye-ring with different shape and colour. Sexes similar. Juvenile has buffy wingbars. Races vary subtly in plumage: *pulverius* is greyest on back and breastband; *trepidus* is slightly less dull than nominate, has dark olive crown that contrasts with brighter olive back, olive breastband; *vigensis* is like nominate, but duller still; *bairdi* is perhaps greener on back, slightly yellower below. Voice. Call "whip", "pwip" or "whiup", distinct from "whit" call of congeners. In N & C Mexico song consists of 2-4 phrases, "prrp, p-wiet, chit p-p-p-p-reer" or "p-rip, p-rip, p'rr-ree", also gives fast alarm trill "dri-i-irr" and "chu-wik" call; song in Chiapas different, "chri-k whee-u', chik-wheer" or "cheenk, cheenk, t-weeree".
Habitat. Interior, edge and semi-open areas within semi-arid to humid pine-oak (*Pinus-Quercus*) forest; 1600-3500 m.
Food and Feeding. Little known. Insects. Forages at low to high levels; similar to *E. hammondii*.
Breeding. Little known. Territorial birds reported in late May (Chiapas). Nest cup placed in fork of tree at middle level of forest. No other information.
Movements. Resident; suspected local wandering during autumn and winter, perhaps becoming more abundant in N part of range in winter.
Status and Conservation. Not globally threatened. Common to fairly common, but often local.
Bibliography. Anon. (1998a), Binford (1989), DeGraaf & Rappole (1995), Fitzpatrick (1980a), Howell & Webb (1995a), Land (1970), Schaldach (1963), Stotz *et al.* (1996), Urban (1959), Wetmore (1941).

238. Pacific-slope Flycatcher

Empidonax difficilis

French: Moucherolle côtier **Spanish**: Mosquero del Pacífico
German: Feuchtwald-Schnäppertyrann
Other common names: Coastal/Redwoods Flycatcher; Western Flycatcher (when grouped with *E. occidentalis*)

Taxonomy. *Empidonax difficilis* S. F. Baird, 1858, Fort Steilacoom, Washington, USA.
Formerly treated as conspecific with *E. occidentalis*; separated on grounds of differences in voice, morphology and allozymes, but this treatment questioned by some authorities; further study perhaps warranted in area where the two contact each other (interior NW of North America). Sometimes *E. flavescens* considered conspecific. Channel Is race *insulicola* possibly a separate species, differs from mainland populations in morphology, voice, habitat use and genetics. Three subspecies recognized.
Subspecies and Distribution.
E. d. difficilis S. F. Baird, 1858 - breeds from SE Alaska S to S California (generally W of Sierra Nevadas) and extreme NW Mexico (N Baja California); winters W Mexico (S to S Baja California, Sinaloa and Oaxaca).
E. d. insulicola Oberholser, 1897 - breeds on Channel Is, off S California (USA); winter range unknown.
E. d. cineritius Brewster, 1888 - Sierra de la Laguna (Victoria Mts), in Cape District (S Baja California).



Descriptive notes. 14-17 cm; 9-12 g. Large-headed flycatcher. Nominate race has indistinct pale supraloral line, distinct white to dull yellowish teardrop-shaped eyering extending to a point behind eye (often slightly broken on top); olive-green crown, distinct slightly bushy crest; ear-coverts, nape and upperparts olive-green, rump browner than back; wings blackish-brown, dingy pale yellow wingbars on median and greater wing-coverts, pale yellow margins of secondaries and tertials (forming panel on secondaries of closed wing); tail fairly long, narrow, dusky; throat dull pale yellow, underparts mustard-yellow with olive wash across chest, belly slightly paler; in worn plumage is greyer above, paler and more whitish below, wingbars and edges of remiges narrower and whiter; iris dark; bill broad, upper mandible black, lower mandible orange-yellow; legs grey. Distinguished from very similar *E. occidentalis* by on average smaller size and smaller bill; from *E. affinis* by chunkier build, shorter wings, more contrast in wingbars, less distinct eyering with different shape and colour, generally wider bill. Sexes similar. Juvenile is similar to adult, but buffy to cinnamon wingbars, more brownish upperparts. Races vary in size and colour: *cineritius* is smallest, back more drab greyish-brown than nominate, also longer wing and longer bill; *insulicola* is larger and greyer, longer-billed and longer-winged than mainland races. Voice. Song "ps-séét ptsick seet" or "tséé-wee pttuck tseep", often rapidly repeated such that intervals between songs no longer than those between the three song elements, some syllables occasionally replaced by position notes. Dawn song similar, "si tí-swéé pi-tik", "si p-séép p-tup" or "whi see-it si-it si-ip p-tik". Male position note upslurred "pee-fst", "pewéáp" or "pawee", similar to "ptsick" component of song (important for distinguishing from *E. occidentalis*); female position note a brief "tsip" or "tsit", similar to "seet" portion of song. Harsh "chrrip", "prrit" or "chrr" during aggressive encounters; soft "peet" often heard during migration (distinct from "whit" or "pic" of many congeners). Other vocalizations include "ti-ti-ti" and "weer-weet-weet" calls. Bill-snapping during aggressive encounters.
Habitat. Breeds in humid to semi-arid pine-oak (*Pinus-Quercus*), coniferous and dense secondary forest, often near streams, ravines and other waterbodies. Habitats include mature second-growth/old-growth Douglas fir (*Pseudotsuga menziesii*), western hemlock (*Tsuga heterophylla*) and mixed coniferous-deciduous forests in coastal British Columbia; also western red cedar (*Thuja plicata*), alder (*Alnus*), cottonwood (*Populus*), willow (*Salix*), sugar pine (*Pinus lambertiana*), incense cedar (*Calocedrus decurrens*) and forests with understorey containing dogwood (*Cornus*), big-leaf maple (*Acer macrophyllum*), currant (*Ribes*) and alder saplings in Washington and Oregon; also redwood (*Sequoia sempervirens*), Pacific madrone (*Arbutus menziesii*), tanoak (*Lithocarpus densiflorus*) and black oak (*Quercus velutina*) in California. On Channel Is (race *insulicola*) drier habitats, including eucalypt (*Eucalyptus*) groves, oak clumps in canyon bottoms, coastal scrub and *Opuntia* cactus. During migration uses shaded forest habitats; shady oases as stopovers through deserts; willows, Monterey cypress (*Cupressus macrocarpa*) and eucalypts along California coast in late summer. Winters in montane evergreen forest, gallery forest, tropical deciduous forest and tropical lowland evergreen forest. Near sea-level to 1310 m in NW North America; 1000-3500 m in Mexico.
Food and Feeding. Arthropods; occasionally fruit. Arthropods include hymenopterans, coleopterans (of family Coccinellidae), bugs (Hemiptera), flies (Diptera), larval and adult lepidopterans, homopteran bugs (Cicadellidae), arachnids; fruits include blackberry (*Rubus*), elderberry (*Sambucus*), tarweed (*Madia*). Searches while perched in low to middle canopy or along margins of riparian vegetation. Sallies out to hawk insects from the air or to glean prey from foliage and branches, average sally distance 1·68 m, afterwards continuing to new perch.
Breeding. Mid-Apr to Jul; double-brooded. Nest a slightly oval cup made of moss, lichens (*Ramalina menziesii*, *Usnea*, *Hypogymnia inactiva*), bark strips and pieces, midribs of large leaves, grass stems, twigs and feathers, bound with spiderweb, lined with fine grass, average external length and width 11·9 × 10·2 cm, internal 4·6 × 2·8 cm; placed in site offering support from below and behind and often with overhead cover, including vertical tree fork, tree cavity, bank shelf, behind loose bark, and artificial structure (building, bridge, roadcut), and often near water; in Alaska 12-28 m up within thick moss covering Sitka spruce (*Picea sitchensis*) or cottonwood branches, in British Columbia 0·3-13 m (mostly 1·3-2·8 m) above ground in tree or shrub including red alder (*Alnus rubra*), wild rose (*Rosa*), Douglas fir, western red cedar, willow, vine maple (*Acer circinatum*), Garry oak (*Quercus garryana*), poplar and spruce; nest-sites reused. Clutch 1-5 eggs, usually 4; incubation period 13-16 days; fledging period 14-17 days. Breeds in first season. Longevity record 6 years.
Movements. Medium-distance migrant, wintering in Mexico; breeding birds in S Baja California (race *cineritius*) resident. Departs breeding grounds late Jul to Oct, adults earlier than juveniles; passes through lower R Colorado (in Arizona) late Jul to mid-Oct; leaves wintering grounds mid-Mar to Jun, peak from mid-Apr to mid-May. Vagrants recorded from Gulf coast of USA and E North America.
Status and Conservation. Not globally threatened. Common to fairly common; overall population estimated at 8,300,000 birds. Densities in California (Douglas fir and oak forest in Humboldt and Trinity counties) 1·3 birds/ha in forest at least 200 years old, 0·8/ha in forest 91-199 years old, and 0·1/ha in forest 30-90 years old. Survey data show no significant trends in population size between 1966 and 1996; although populations on Vancouver I (Canada) appeared to increase by 5·3% annually, numbers declined in Douglas fir forests of NW California. Has extended its range N in British Columbia.
Bibliography. Ainsley (1992), Anon. (1998a), Armstrong (1983), Baicich & Harrison (1997), Bailey (1983), Bent (1942), Binford (1989), Campbell *et al.* (1997), Cory & Hellmayr (1927), Davis *et al.* (1963), DeGraaf & Rappole (1995), Faxon & Bayer (1991), Frakes & Johnson (1982), Fitzpatrick (1980a), Gabrielson & Lincoln (1959), Howell & Webb (1995a), Hutto (1980), Johnson, N.K. 239. Cordilleran Flycatcher

Empidonax occidentalis

French: Moucherolle des ravins **Spanish**: Mosquero Cordillerano
German: Hochland-Schnäppertyrann
Other common names: Western Flycatcher (when grouped with *E. difficilis*)

Taxonomy. *Empidonax bairdi occidentalis* Nelson, 1897, Pluma, Oaxaca, Mexico.
Formerly treated as conspecific with *E. difficilis*; separated on grounds of differences in voice, morphology and allozymes, but this treatment questioned by some authorities; further study perhaps warranted in area where the two contact each other (interior NW of North America). Geographical variation in size and colour perhaps clinal. Two subspecies recognized.
Subspecies and Distribution.
E. o. hellmayri Brodkorb 1935 - breeds interior W North America from S Canada (WC Alberta, N Rocky Mts region) and USA (S to NE California, S Nevada, C & SE Arizona, SW Texas) S to N Mexico (Sierra Madre Occidental of Sonora and Chihuahua, and N Coahuila); winters Mexico.
E. o. occidentalis Nelson 1897 - highlands of Mexico, from Durango, SE Sinaloa, SE Coahuila and Nuevo León S to Guerrero, SC Oaxaca and W Veracruz.

Descriptive notes. 13-17 cm; 9-12 g. Large-headed flycatcher. Has indistinct pale supraloral line, distinct white to dull yellowish teardrop-shaped eyering extending to a point behind eye (often slightly broken on top); olive-green crown, distinct slightly bushy crest; ear-coverts, nape and upperparts olive-green, rump browner than back; wings blackish-brown, dingy pale yellow wingbars on median and greater wing-coverts, pale margins of secondaries and tertials (forming panel on secondaries of closed wing); tail fairly long, narrow, dusky; throat dull pale yellow, underparts mustard-yellow, olive wash across chest, belly slightly paler; in worn plumage is greyer above, paler and more whitish below, wingbars and edges of remiges narrower and whiter; iris dark; bill broad, upper mandible black, lower mandible orange-yellow; legs grey. Distinguished with difficulty from *E. difficilis* by on average heavier build and larger bill, greener coloration above, yellower below; from *E. affinis* by generally wider bill, also chunkier shape and shorter wings, more contrast in wingbars, less distinct eyering with different shape and colour. Sexes similar, female on average slightly smaller than male. Juvenile has buffy to cinnamon wingbars, more brownish upperparts. Race *hellmayri* is larger than nominate, brighter on breast, with longer wing and bill. Voice. Song "ps-séét ptsick seet" or "tséé-wee pttuck tseep", often rapidly repeated such that intervals between songs no longer than those between the three song elements, some syllables occasionally replaced by position notes. Dawn song similar, "sii swéé'ín pi-luk or "si wéé-éé pi-dik". Male position note "pit-péét" or "wee-eee" (important for distinguishing from *E. difficilis*); female position note a brief "tsip" or "tsit", similar to "seet" part of song. Soft "peet" often heard during migration (distinct from "whit" or "pic" of many congeners). Bill-snapping during aggressive encounters.
Habitat. Breeds in humid to semi-arid pine-oak (*Pinus-Quercus*) and coniferous forest, often near streams, ravines or openings, typically including Engelmann spruce (*Picea engelmannii*), lodgepole pine (*Pinus contorta*), ponderosa pine (*P. ponderosa*), Jeffrey pine (*P. jeffreyi*), white fir (*Abies concolor*), quaking aspen (*Populus tremuloides*) and black cottonwood (*P. trichocarpa*); also subalpine fir (*A. lasiocarpa*) and bristlecone pine (*P. longaeva*) in Nevada; birch (*Betula*), ponderosa pine with understorey of maple, chokecherry (*Prunus virginiana*), and chapparal in South Dakota; Douglas fir (*Pseudotsuga menziesii*), white fir, ponderosa pine, white pine (*Pinus strobiformis*), Gambel's oak (*Quercus gambelii*), and understorey of canyon maple (*Acer grandidentatum*) and New Mexico locust (*Robinia neomexicana*) in Arizona; forested canyon bottoms of basswood (*Tilia*), maple, Douglas fir and oaks in Sierra de Carmen (N Coahuila, in Mexico). During migration uses shaded forest habitats; shady oases as stopovers through deserts. Winters in montane evergreen forest, gallery forest, tropical deciduous forest, tropical lowland evergreen forest. Perhaps prefers more cool, arid and dense habitats than *E. difficilis*. At 1000-3500 m in Mexico; above 2600 m in Arizona snowmelt drainages.
Food and Feeding. Insects; occasionally fruit. Searches for prey while perched 0-9 m up; sallies usually 1-2 m to hawk insects from the air or to glean prey from foliage and branches, afterwards continuing to new perch.
Breeding. Late Apr to Jul in Canada and USA, and Mar-Sept in Mexico; double-brooded. Nest a cup made of green moss, bark strips and rootlets, bound by spiderweb, placed 0·2-9 m up in site offering support from below and behind and often with overhead cover, including rock face and outcropping, tree cavity, root mass of upturned tree, tree stump, between shelf fungus and tree trunk, streambank, rotten log and artificial structure; old nest-sites reused. Clutch 2-5 eggs, usually 3-4; no information on incubation and fledging periods.
Movements. N populations medium-distance migrants, wintering in Mexico. Generally departs breeding grounds in USA late Aug and Sept; arrives on breeding grounds in USA mid-Apr to mid-May. In Mexico, most descend to foothills and Pacific lowlands, and to 600-1500 m on Atlantic slope, in winter.
Status and Conservation. Not globally threatened. Common to fairly common; total population estimated at 2,600,000 birds. Survey data show no significant decline or increase in population size between 1966 and 1996.
Bibliography. Andrews & Righter (1992), Anon. (1998a), Baicich & Harrison (1997), Bailey (1983), Binford (1989), Brawn & Balda (1988b), Campbell *et al.* (1997), DeGraaf & Rappole (1995), Dorn & Dorn (1990), Gilligan *et al.* (1994), Hejl *et al.* (1995), Howell & Webb (1995a), Johnson, A. 240. Yellowish Flycatcher

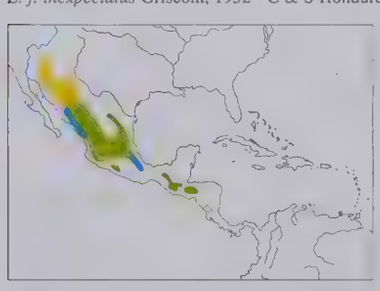
Empidonax flavescens

French: Moucherolle jaunâtre **Spanish**: Mosquero Amarillento
German: Sumpfschnäppertyrann
Other common names: Interior/Ponderosa Flycatcher

Taxonomy. *Empidonax flavescens* Lawrence, 1865, Barranca, Costa Rica.
Sometimes considered conspecific with *E. difficilis*. Three subspecies recognized.
Subspecies and Distribution.
E. f. salvini Ridgway, 1886 - highlands of SE Mexico (S from E Oaxaca) S to N Nicaragua.
E. f. imperturbatus Wetmore, 1942 - Sierra de Tuxtla, in SE Veracruz (Mexico).
E. f. flavescens Lawrence, 1865 - highlands of Costa Rica and W Panama.



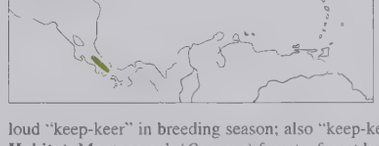
Descriptive notes. 12·5-14 cm; 12 g. Nominate race has indistinctly pale lores, prominent pale yellow teardrop-shaped eyering extending to point behind eye; crown olive-green, slightly crested; head side, nape and upperparts bright olive-green; wings and tail dusky brown, two dull brown wingbars, buffier or yellowish margins of secondaries and tertials (forming panel on secondaries of closed wing); throat pale yellow, breast washed olive and sometimes tinged ochre, belly and vent yellow; iris dark; bill broad, upper mandible black, lower mandible orange-yellow; legs grey. Distinguished from *E. difficilis* and *E. occidentalis* by brighter overall coloration, browner wingbars, perhaps bolder eyering. Sexes similar. Juvenile is brownish-olive above, wingbars broader and buffy to cinnamon, browner on chest, paler yellow below, almost white on belly. Race *salvini* is slightly darker above than nominate, more extensively olive without ochre tinge below, breastband less distinct from belly, belly more olive-yellow; *imperturbatus* is similar to previous. Voice. Call a high thin "seee", "tseeep", "tsee'n" or "see-ip", much like that of *E. occidentalis*, or shorter "tsick" notes given in series. Dawn song, from high perch, a high thin "si-iin ch-ik w-seein" or "see see chit" (sometimes without the "ch-ik" or "chit" note), 20 times per minute.
Habitat. Openings and borders of cool moist montane evergreen and broadleaf forests and mixed pine (*Pinus*) forest, also shady pastures and second growth; also plantations and gardens. At 900-3000 m in Mexico; in Costa Rica, 800-2150 m on Caribbean slope and 1200-2450 m on Pacific slope.
Food and Feeding. Food primarily insects and spiders, also some berries. Searches for prey from low to high perches; sits upright, flicks tail. Uses short aerial sallies and hover-glean manoeuvres directed to air, foliage, bark and the ground. Does not associate with mixed flocks.
Breeding. Mar-Jun in Costa Rica. Nest a cup made of moss, liverworts and rootlets, lined with fine plant fibres, grasses, hair and papery bark, placed 2-4·5 m up in vertical fork or within depression in large trunk, earthen bank or cliff, often hidden by overhanging vegetation. Clutch 2-3 eggs; no other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Given its tolerance of converted habitat, it is considered not likely to become threatened in near future. Occurs in Tapantí National Park, in Costa Rica.
Bibliography. Anon. (1998a), Binford (1989), Blake, E.R. (1953, 1958), Cory & Hellmayr (1927), Dearborn (1907), Fitzpatrick (1980a), Gómez de Silva *et al.* (1999), González-García (1993), Henderson (2002), Howell & Webb (1995a), Johnson, N.K. (1980), Land (1970), Monroe (1968), Paynter (1957), Ridgely & Gwynne (1989), Ridgway (1907), Rowley (1984), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1943, 1972).

241. Buff-breasted Flycatcher

Empidonax fulvifrons

French: Moucherolle beige **Spanish**: Mosquero Pechicanelo
German: Orangebrust-Schnäppertyrann

Taxonomy. *Muscicapa fulvifrons* Giraud, 1841, Miquiahuana, Tamaulipas, Mexico.
Validity of several races doubted, nominate and *brodkorbi* known only from holotype specimens; further work necessary. Six subspecies currently recognized.
Subspecies and Distribution.
E. f. pygmaeus Coues, 1865 - SW USA (EC & SE Arizona, at least formerly WC & SW New Mexico) and NW Mexico (Sonora, S Coahuila); winters SC Mexico (S to Michoacán and Morelos).
E. f. rubicundus Cabanis & Heine, 1859 - highlands in C Mexico locally from Durango S to Morelos and Puebla; winters S to Guatemala.
E. f. fulvifrons (Giraud, 1841) - Tamaulipas (E Mexico).
E. f. fusciceps Nelson, 1904 - highlands of S Mexico (from Oaxaca) S locally to Guatemala and El Salvador.
E. f. brodkorbi A. R. Phillips, 1966 - S Oaxaca (S Mexico).
E. f. inexpectatus Griscom, 1932 - C & S Honduras.



Descriptive notes. 11·5-13 cm; 8 g. Small, distinctively coloured *Empidonax*. Nominate race has pale supraloral line, prominent white eyering; rest of head and nape and upperparts brown to grey-brown; wings dusky brown, two prominent cinnamon-buff to white wingbars, white to pale yellow margins of secondaries and tertials (forming panel on secondaries of closed wing); tail dusky, white outer web of outer rectrix; pale orange-buff below, darkest on breast; plumage varies with wear, brown tones strongest when fresh, greyest when worn, warm tones of underparts become paler buff with wear; iris dark brown; bill short, small and wide, upper mandible black, lower mandible orange-yellow; legs black. Sexes similar. Juvenile is similar to adult, but wingbars broader and brighter cinnamon. Races vary in plumage: *rubicundus* has warm brown crown and back, resembles nominate; *inexpectatus* has dark brown crown contrasting with back, darker brown upperparts and wings than previous; *pygmaeus* is smaller, dull pale grey above, paler buff below, much paler throat and belly; *fusciceps* is darker and more richly coloured. Voice. Common call "pit" or "pic". Song, by both sexes during breeding, male from perch 1-20 m high, a series of sharp short phrases, "p-teek, pit p-teek pi-tik, peek pi-chu…", "sipit siu, sipit piu", or "chee-lick" or chee-lick chou" (with "chou" sometimes trilled). Also "quit-quit" or "quit-quit-quir-r-r" as alarm. Bill-snapping while foraging also reported.
Habitat. Breeds in scrub, pastures, and pine (*Pinus*) and oak (*Quercus*) woodland with open understorey, grass and small trees, often in wide canyons or near riparian vegetation. Also oak forest and riparian woodland of sycamore (*Platanus*), cottonwood (*Populus*) and willow (*Salix*) during migration. Winters habitats similar to breeding ones, at lower elevations, as well as thornscrub near riparian woodland. Breeds at 1000-3500 m, in S USA 1950-2850 m, in Honduras and Guatemala 600-2600 m; winters mostly at 600-2500 m, sometimes lower, near sea-level.
Food and Feeding. Arthropods, including hymenopterans, hemipterans, Beetles (Coleoptera), orthopterans, lepidopterans, dragonflies and damselflies (Odonata), neuropterans, arachnids. Searching for prey from perch on tree branch, bush or weed stem, usually at low to middle levels, sometimes in canopy; prey captures made in flight, using short (0·5-3 m) sallies directed to the air or ground.
Breeding. Late May to Jul in USA (Arizona) and mid-Mar to mid-Sept in Mexico. Nest constructed by female, an oval-shaped cup of small rootlets, herbaceous leaves, grass and conifer needles, bound by spiderweb, outside adorned with bark pieces, lichen, leaves and feathers, average outside height 6 cm, length and width 8·5 × 7 cm, inside depth 3·8 cm, length and width 4·4 × 3·3 cm; 2·7-12 m up in sloping fork, on branch or crotch of main trunk at middle level of tree, often protected above by foliage, frequently in Chihuahuan pine (*Pinus leiophylla*), ponderosa pine (*P. arizonica*), Arizona sycamore (*Platanus wrightii*), Arizona white oak (*Quercus arizonica*), Douglas fir (*Pseudotsuga menziesii*) or other tree on hillside or canyon bottom. Clutch 2-5 eggs, usually 3-4; incubation period 14-16 days; fledging period 15-17 days. Average 2·08 fledglings/nest over entire breeding season in USA (Arizona).
Movements. Mainly resident; N populations migrate S and others move downslope in winter. Populations in Arizona and N Sonora leave breeding grounds mid-Aug to mid-Sept, winter in C & S Sonora, return to breeding grounds late Mar/Apr. Some Mexican birds may descend to lower elevations Sept-Apr. Also recorded Nov-Mar in N El Salvador.
Status and Conservation. Not globally threatened. Uncommon to common or fairly common; overall population estimated at 2,000,000 birds. Disappeared from USA during last century; recently, range has apparently expanded N again, but still rather rare and local in SW USA. Natural fires may be important in maintaining preferred open habitats in Arizona, populations possibly increasing following burns. Overgrazing and fire suppression may degrade suitable breeding habitats, while loss and alteration of wooded habitats in Mexico may also have a negative effect.
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bent (1942), Binford (1989), Blake & Hanson (1942), Bowers & Dunning (1994), Cory & Hellmayr (1927), Cottam & Knappen (1939), Dearborn (1907), DeGraaf & Rappole (1995), Fitzpatrick (1980a), Fleming & Baker (1963), González-García (1993), Hejl *et al.* (1995), Howell & Webb (1995a), Hutto (1992), Kaufman (1996), Land (1970), Lowery & Dalquest (1951), Martin & Morrison (1998, 1999), Mlodinow & O'Brien (1996), Monroe (1968), Ridgway (1907), Rowley (1966), Schaldach (1963), Stejskal & Witzeman (1984, 1985), Stotz *et al.* (1996), Thurber *et al.* (1987), Udvardy (1963), Urban (1959).

242. Black-capped Flycatcher

Empidonax atriceps

French: Moucherolle à tête noire **Spanish**: Mosquero Cabecinegro
German: Schwarzkappen-Schnäppertyrann

Taxonomy. *Empidonax atriceps* Salvin, 1870, Volcán de Chiriquí, Panama.
Monotypic.
Distribution. Cordilleras of Costa Rica and W Panama (W Chiriquí and adjacent Bocas del Toro).

Descriptive notes. 11·5 cm; 9 g. Has bold white eyering, broken above eye, broad at rear; short-crested black crown contrasts with brownish-olive head side, nape and upperparts; wings dusky, two pale brown wingbars, pale brown margins of secondaries and tertials; tail dusky, white outer webs of outer rectrices; throat white, underparts pale buffish-cinnamon; iris dark; upper mandible black, lower mandible orange-yellow with dark tip; legs blackish. Sexes similar. Juvenile is similar to adult, but black cap slightly duller, upperparts browner, wingbars and margins of remiges buffy, belly paler. Voice. Call a simple whistled "tsip", "chip" or "whit"; loud "keep-keer" in breeding season; also "keep-keep-keep-keep" during interactions.
Habitat. Montane oak (*Quercus*) forests, forest borders and clearings, brushy second growth, pastures, and edges of *páramo*. In Costa Rica 2450-3300 m, locally down to 2100 m, and may descend to 1850 m at height of rainy season; mainly above 2100 m in Panama.
Food and Feeding. Insects, including dipterans, coleopterans and lepidopterans. Searches for prey from exposed perch, either high in canopy of montane forest or low on top of small bush or fence; perches upright. Uses aerial-sally manoeuvres, afterwards often returning to same perch; quickly flicks tail up and vibrates it upon landing.
Breeding. Mar-May. Nest a cup made of fine grass and moss, lined with fine plant fibres, horsehair, small feathers and bear lichen (*Usnea*), 2-12 m above ground, either saddled in upright fork in tree or shrub, or suspended from attached grass below edge of low embankment. Clutch 2 eggs; no other information.
Movements. Presumably resident; some move downslope during height of rainy season.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Fairly common to common. Highland forests in this species' range have been extensively destroyed by burning, logging and agricultural conversion; 50% of Costa Rica's forests destroyed since 1940, and current deforestation rate of c. 3% means that soon forests will survive only in protected areas. In Panama E of Chiriquí, only forest fragments remain, and local extinction of forest-dependent species is likely; this tyrannid is, however, fairly common in shrubby clearings along upper Boquete Trail above Cerro Punta. Perhaps benefits from shrubby second-growth vegetation arising following habitat disturbance or pasture abandonment.

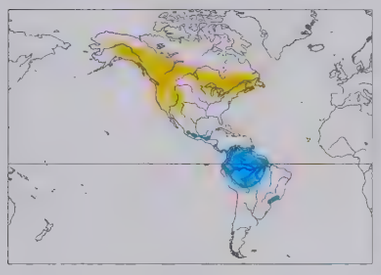
Genus *CONTOPUS* Cabanis, 1855



243. Olive-sided Flycatcher

Contopus cooperi

French: Moucherolle à côtés olive **German**: Olivflanken-Schnäppertyrann **Spanish**: Pibí Boreal

Taxonomy. *Muscicapa cooperi* Nuttall, 1831, latitude 54° N, banks of the River Saskatchewan, Canada. Formerly placed in a monotypic genus, *Nuttallornis*; also, previously referred to as *C. borealis*, but that name preceded by present one. Closest relatives possibly *C. fumigatus*, *C. sordidulus* and *C. virens*. Larger birds in SW (S California, N Baja California) sometimes treated as a geographical race, *marjorinus*. Monotypic.

Distribution. Breeds from N & W Alaska E across C Canada to Maritime Provinces, and S in USA to N California, also locally into NW Mexico (Baja California), in interior through Idaho and W Montana to NE Arizona and NW New Mexico and, in E, to boreal regions of Adirondacks and New England. Winters locally in W & S Mexico (from Jalisco and S Veracruz) S to Panama and (mainly in mountainous regions) from Colombia and Venezuela S to SE Peru and NW Bolivia; more locally in the Guianas, S Amazonia (from lower R Amazon S to C Bolivia and Tapajós basin) and SE Brazil.

Descriptive notes. 18-20 cm; 32-37 g. Stout, large-headed, short-tailed flycatcher with peaked crest. Has head and upperparts drab brownish or grey-olive, wings dusky, indistinct dull greyish wingbars, whitish edging on inner secondaries and tertials; long primary projection; tail dusky; white below, duller on belly, with sides and flanks contrastingly streaked dusky olive (distinct vested appearance), undertail-coverts with dull brownish-grey feather centres; white tuft on flanks occasionally visible above wings; iris dark; bill broad, upper mandible black, lower mandible pale orange with dark tip; legs blackish. Sexes similar. Juvenile is similar to adult, but browner overall, buff wash on wingbars and margins of tertials. Voice. Song, mainly by male on breeding grounds, a sharp and penetrating loud 3-note whistle, "whit, whee-pew" or "whip wéédéér" ("quick, three beers"); song of Pacific birds reported as slightly different, "what peeves yoou" with no syllable emphasized. Call 3 evenly spaced hard notes, "pip, pip, pip" or "bik-bik-bik", by both sexes throughout year. Other vocalizations include song-call combination, "peer-pip", by male; twittering "pip"-like notes by both sexes near nest, in greeting or on landing after prey capture; squeaky "eek" sometimes during attack-flights against predators. Nestling begging call "cheep-cheep", reminiscent of call of Pine Siskin (*Carduelis pinus*). Bill-snapping during aggressive encounters.

Habitat. Breeds in montane and coniferous forests, forest openings, edges, burned areas, borders of streams, bogs and other wetlands with prominent snags; habitat includes Douglas fir (*Pseudotsuga menziesii*), grand, red and balsam firs (*Abies grandis*, *A. magnifica*, *A. balsamea*), western red cedar (*Thuja plicata*), western and eastern hemlocks (*Tsuga heterophylla*, *T. canadensis*), various pines (*Pinus contorta*, *P. ponderosa*, *P. banksiana*, *P. rigida*), red, white and black spruces (*Picea ribens*, *P. glauca*, *P. mariana*), tamarack (*Larix laricina*), aspen (*Populus*). Mainly montane habitats during migration, but also riparian forests in W USA and pine-oak (*Pinus-Quercus*) forest and evergreen and semi-deciduous forests in Central America. Winters in forest edges, forest openings and second growth where snags present. Breeds sea-level to 3350 m; winters 400-3400 m.

Food and Feeding. Insects, including hymenopterans, dipterans, lepidopterans, orthopterans, Odonata, and coleopterans (Scolytidae). Searches for prey while sitting upright on high exposed perch; in Venezuela, can be found on same perch for weeks. Prey captured by sallying, often returning to same perch.

Breeding. Late May to Aug. Cup-nest built by female, of twigs and rootlets, often lined with *Usnea* beard lichen, grass and pine needles, average outside diameter 11·8 cm, inside 7 cm (Oregon), outside diameter 13·4 cm, inside 6·1 cm (Alaska); generally placed towards tip of horizontal branch in conifer, although other trees sometimes used. Clutch 2-5 eggs, usually 3-4; renesting may occur if first nest fails; incubation period 14-19 days; fledging period usually 15-23 days. Success: 62% of pairs in Alaska and 65% of pairs in NW Oregon successfully fledge more than 1 young. Longevity record at least 7 years.

Movements. Long-distance migrant, wintering in Central and South America; longest migration route of any North American tyrannid. Nocturnal migrant. Most migrate through W USA and Central America, occurring more locally on passage in E and occasionally along coastal SE Atlantic and Gulf coast states. Departs breeding grounds early Aug to early Sept, passing through Mexico Aug to early Nov; arrival in Costa Rica and Panama mid-Sept to mid-Nov, in South America in Oct-Nov. Greatest winter abundances in Colombia. Leaves wintering grounds late Mar/Apr, rarely as late as mid-May, passing through Mexico Apr to early Jun, arriving on breeding grounds from Apr to late May. Migration routes through forests of W North America and Central America, routes (and habitat use) may vary between spring and autumn migrations. Vagrants recorded from Bering Sea islands, Greenland, Bermuda, SE Brazil and coastal S Peru.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Global population estimated at 1,200,000 individuals. Survey data show overall decline of 67% across breeding range from 1966 to 1996, declines accelerating in later half of this period, especially in core areas W of Rocky Mts. Factors limiting population unknown, but habitat loss, particularly deforestation on wintering grounds in Andean foothills, suspected; considered uncommon and declining in South America. This genus has lowest reproductive rate of all passerine genera in North America, thereby increasing the importance of winter survival to general demographic trends. In breeding range, fire suppression may also reduce suitable habitat, as this species may have been historically dependent on post-fire habitats; acid rain threatens forest habitat in S Appalachians. Listed by US Fish & Wildlife Service as a species of concern; listed as "endangered" in Maryland. North American Landbird Conservation Plan considers this to be a "Watch List" species, with a goal of increasing its population size by 100%.

244. Greater Pewee

Contopus pertinax

French: Moucherolle de Coues **German**: Großer Schnäppertyrann **Spanish**: Pibí Tengofrío
Other common names: Coues's Flycatcher

Taxonomy. *C[ontopus] pertinax* Cabanis and Heine, 1859, Jalapa, Veracruz, Mexico.
Formerly placed in genus *Myiochanes*. May form a superspecies with *C. lugubris* and *C. fumigatus*, and formerly treated as a race of latter. Geographical plumage variation slight and clinal, and populations also differ in voice; further study needed. Pale-bellied birds from N of range sometimes separated as race *pallidiventris*, but better merged with nominate. Two subspecies recognized.

Subspecies and Distribution.
C. p. pertinax Cabanis & Heine, 1859 - breeds SW USA (C & SW Arizona, SW New Mexico) and W & C Mexico (S to Isthmus of Tehuantepec); winters S to Guatemala and Belize.
C. p. minor (W. deW. Miller & Griscom, 1925) - S Mexico (mainly E of Isthmus of Tehuantepec), Guatemala and Belize S to NC Nicaragua.

Descriptive notes. 17-19 cm; 27 g. Has indistinct pale supraloral area and dark lores; crown dark grey to greyish-olive, tufted; rest of head and nape and upperparts drab grey to greyish-olive; wings and tail dusky, pale tips of median and greater wing-coverts (two faint wingbars), whitish to pale brown margins of secondaries and tertials; pale grey below, belly tinged yellow; iris dark; upper mandible black, lower mandible yellow-orange; legs blackish. Differs from *C. cooperi* in longer tail, tufted crest, greyer overall coloration, brighter lower mandible. Sexes similar, female tail and wing lengths on average shorter than male's. Juvenile is similar to adult, but wingbars cinnamon-buff, margins of secondaries pale yellow-buff, belly and undertail-coverts tinged pale buff or pale ochre. Resident race *minor* has shorter wings and tail than migratory nominate, is also smaller and darker. Voice. Call "pip-pip-pip" or "beek beek beek", similar to that of congeners; call of race *minor* described as loud "quip-quip" or "wic-wic-wic". Male song a plaintive "wheee tee whee-wheu" or "Ho-say ma-ree-ah", sometimes preceded by extra "ho-say" notes or followed by short "whee di-irit" or "chewdl-it" phrases. Dawn song (*minor*) "fred-rick-fear", middle note ascending in pitch, "fear" lower, similar to *C. lugubris*.

Habitat. Breeds in pine (*Pinus*) and pine-oak (*Pinus-Quercus*) woodland in mountains; some use riparian and broadleaf forest in winter. In general, occurs at 750-3500 m, descending locally to 250 m in winter; 2100-3000 m in N of range, 1360-2575 m in S Mexico (Oaxaca), 1060-1500 m in El Salvador; down to 400 m in Belize.

Food and Feeding. Insects during breeding season; some fruit in winter. Forages in erect stance from exposed perch (e.g. end of dead branch, top of pine); mean perch height (Arizona) 18 m, intermediate between higher-perching *C. cooperi* and lower-perching *C. sordidulus*. Captures prey by sallying from perch greater than 16 m, returning to same perch; also moves between foraging perches often several hundred metres apart. In autumn, single individuals reported within mixed-species flocks passing through the bird's territory.

Breeding. May-Jul; pair-forming in Mar in El Salvador. Cup-nest made of grass, bark, pine needles, pine cones, oak catkins and contour feathers, outside covered with lichens and spiders' web, external diameter 10·2-13·5 cm, height 5·1-8 cm, internal diameter 7·6 cm, depth 2·5-5 cm; placed near tip of large branch, often within fork, on average 11·62 m high in Huachuca Mts (Arizona). Clutch 2-4 eggs; no information on incubation and fledging periods; vigorously attacks potential nest predators. In SE Arizona, 53% of females rear at least one brood to fledging.

Movements. Partial short-distance migrant. N populations migrate S in winter; leave SE Arizona breeding grounds by end Sept; return as early as late Mar, via mountainous routes at 1500 m. Some Mexican individuals winter in breeding habitat, others move downslope to riparian areas; Sonora birds move to lower elevations in late Aug. No seasonal altitudinal movements in Belize, El Salvador and Honduras.

Status and Conservation. Not globally threatened. Common to fairly common. Global population estimated at 2,000,000 individuals. Densities in mountains of SE Arizona low, 0·05-0·17 birds/ha; more abundant in Sierra Madre of N Sonora, in Mexico. Protection of pine-oak forest for breeding Spotted Owl (*Strix occidentalis*) and Northern Goshawk (*Accipiter gentilis*) should also benefit this tyrannid.

Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bent (1942), Binford (1989), Blake, E.R. (1953), Chace & Tweit (1999), Cory & Hellmayr (1927), Dearborn (1907), DeGraaf & Rappole (1995), Fitzpatrick (1980a), Fleming & Baker (1963), Howell & Webb (1995a), Hutto (1980, 1992), Kaufman (1996), Land (1970), Lee Jones (2004), Monroe (1968), Price *et al.* (1995), Ridgway (1907), Rowley (1966), Schaldach (1963), Smithe (1966), Stotz *et al.* (1996), Udvardy (1963), Wetmore (1941).

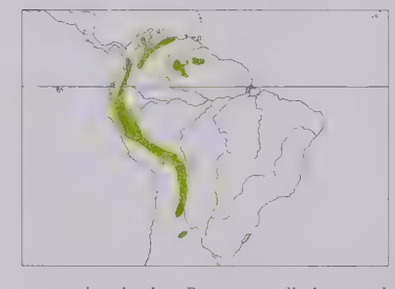
245. Dark Pewee

Contopus lugubris

French: Moucherolle ombré **German**: Trauerschnäppertyrann **Spanish**: Pibí Oscuro

On following pages: 246. Smoke-coloured Pewee (*Contopus fumigatus*); 247. Ochraceous Pewee (*Contopus ochraceus*); 248. Western Wood-pewee (*Contopus sordidulus*); 249. Eastern Wood-pewee (*Contopus virens*); 250. Tropical Pewee (*Contopus cinereus*); 251. Cuban Pewee (*Contopus caribaeus*); 252. Jamaican Pewee (*Contopus pallidus*); 253. Hispaniolan Pewee (*Contopus hispaniolensis*); 254. Lesser Antillean Pewee (*Contopus latirostris*); 255. White-throated Pewee (*Contopus albogularis*); 256. Blackish Pewee (*Contopus nigrescens*); 257. Tufted Flycatcher (*Mitrephanes phaeocercus*); 258. Olive Flycatcher (*Mitrephanes olivaceus*).

Taxonomy. *Contopus lugubris* Lawrence, 1865, Barranca, Costa Rica.
Closely related to *C. pertinax* and *C. fumigatus*; formerly considered a race of latter. Monotypic.
Distribution. Mountains of Costa Rica and extreme W Panama.



Descriptive notes. 16·5 cm; 23 g. Large, crested pewee. Has head and upperparts uniform dark sooty olive-grey, darkest on crown; wings and tail blackish, wing-coverts faintly tipped grey (wingbars), grey margins of secondaries and tertials; fairly uniform dull grey below, throat perhaps slightly paler, belly tinged buff, undertail-coverts grey with buff edges; iris dark; bill broad, upper mandible black, lower mandible orange-yellow; legs blackish. Differs from *C. cooperi* in longer tail, more obvious crest, much more uniform coloration. Sexes similar. Juvenile resembles adult, but browner on upperparts, throat and breast, rufous feather fringes on rump and uppertail-coverts, paler buffy white on belly. Voice. Frequently repeated call a loud "wic", "whip" or "pip pip pip"; also loud "weer". Dawn song, from treetop during breeding, "fred-rick-fear", middle note ascending, and "fear" part lower.
Habitat. Humid montane forest, forest borders and clearings with scattered trees; 1200-2150 m in Costa Rica, 900-2250 m in Panama.
Food and Feeding. Insects. Searches for prey from high perch, often exposed dead branch or top of tree, stance upright; captures prey with long sallies, often returning to same perch afterwards; vibrates tail upon landing.
Breeding. Mar-Jun. Nest a broad shallow cup made of green moss, liverworts and lichens, bound by spiderweb, lined with rootlets and coarse plant fibres, placed 5-18 m up, saddled over descending branch; mobs Emerald Toucanets (*Aulacorhynchus prasinus*) during nesting season. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Uncommon to fairly common. Highland forests in species' range have been extensively destroyed by burning, logging and agricultural conversion. In Costa Rica, 50% of forests destroyed since 1940, and current deforestation rate of c. 3% annually means that soon forests will survive only in protected areas.
Bibliography. Anon. (1998a), Blake (1958), Chace & Tweit (1999), Cory & Hellmayr (1927), Delgado (1985), Eisenmann (1955), Ridgely & Gwynne (1989), Ridgway (1907), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

246. **Smoke-coloured Pewee**

Contopus fumigatus

French: Moucherolle bistré **German**: Schieferschnäppertyrann **Spanish**: Pibí Ahumado

Taxonomy. *T[yrannus] fumigatus* d'Orbigny and Lafresnaye, 1837, Yungas of Bolivia.
Formerly considered conspecific with *C. pertinax* and *C. lugubris*. Race *ardosiacus* thought by some authors to be possibly a separate species; further study required. Validity of some other races questionable. Six subspecies recognized.
Subspecies and Distribution.
C. f. ardosiacus (Lafresnaye, 1844) - Colombia (except SW), extreme W & SW Venezuela, E Ecuador and E Peru.
C. f. cineraceus (Lafresnaye, 1848) - N Venezuela.
C. f. duidae (Chapman, 1929) - S Venezuela and Guyana.
C. f. zarumae (Chapman, 1924) - SW Colombia and W Ecuador to NW Peru.
C. f. fumigatus (d'Orbigny & Lafresnaye, 1837) - SE Peru and N Bolivia.
C. f. brachyrhynchus Cabanis, 1883 - SE Bolivia S to NW Argentina.

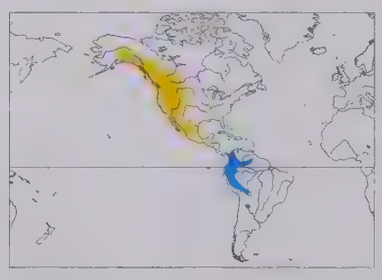
Descriptive notes. 16-17 cm; 18·2 g. Nominate race has dark grey crown with crest, indistinct paler supraloral stripe; upperparts fairly uniform grey, sometimes tinged olive, rump sooty grey; wings duskier, pale brown tips of wing-coverts (two narrow indistinct wingbars) and edges of tertials; tail dusky; grey below, throat slightly paler, lower belly and undertail-coverts yellowish-white; iris dark; upper mandible black, lower mandible orange-yellow; legs black. Sexes similar. Juvenile is more brownish overall than adult, feathers of upperparts (especially nape) fringed buff, 2-3 narrow ochre wingbars, belly and undertail-coverts tinged ochre. Races generally become darker and greyer towards N: *brachyrhynchus* is paler overall than nominate, greyer crown contrasts less with back, has much paler whitish throat, more extensive pale area on belly; *duidae* is smaller, darker bluish-grey overall, wings more blackish than nominate, throat and underparts all dark smoky grey, but juvenile has whitish on lower belly; *ardosiacus* has more uniform grey underparts, lower belly and undertail-coverts grey, paler than breast (but not white); *cineraceus* and *zarumae* are very like nominate. Voice. Most frequent call a loud "pip pip pip"; also repeated clear whistled "peeew". Rarely heard song a hoarse "zur zur zur zúr zur zur zur" (Andes). Dawn song in N Venezuela (race *cineraceus*) a whistled "whueer", "whueer, whu-u'whuet", "whueer, wheerit" or "peer-peereét", reminiscent of *C. cooperi* song; in Argentina (*brachyrhynchus*) a more subdued "per-wheer", reminiscent of a *Spizaetus* hawk-eagle. Also gives single "rrhy" and short "pjeek" or "pjeek pjeek" notes.
Habitat. Humid montane forest, forest borders and clearings with scattered trees. Usually at 1000-2500 m, sometimes to 3000 m in Andes, locally down to near sea-level in SW Ecuador; in Venezuela, 500-2800 m N of R Orinoco and 900-1900 m S of it.
Food and Feeding. Insects. Searches for prey from low to high perch, often exposed dead branch, top of tree, or lower fallen tree; perches erect. Captures prey in long aerial sallies, often returning to same perch afterwards; vibrates tail upon landing.
Breeding. Cup-nest made of moss and lichen, saddled on horizontal branch high in tree. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Fairly common to common. Has relatively large range and is tolerant of disturbed habitat. Occurs in many national parks and other protected areas throughout range, including almost every protected reserve in its Andean range.
Bibliography. Anon. (1998a), Baez *et al.* (1997), Canevari *et al.* (1991), Chapman (1917c, 1931), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Di Giacomo & López (1998), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hilty (1997, 2003), Hilty & Brown (1986), Mayr & Phelps (1967), Meyer de Schauensee (1982), Miller (1963), Nores *et al.* (1983), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Walker (2001), Wetmore (1939), Williams & Tobias (1994), Zimmer (1930, 1939a).

247. **Ochraceous Pewee**

Contopus ochraceus

French: Moucherolle ocré **German**: Ockergelb-Schnäppertyrann **Spanish**: Pibí Ocráceo

Taxonomy. *Contopus ochraceus* P. L. Sclater and Salvin, 1869, Costa Rica. Monotypic.
Distribution. Highlands of Costa Rica, rarely also extreme W Panama (Chiriquí).



Descriptive notes. 16·5 cm; 23 g. Large, crested pewee. Has crown and crest dark brownish-olive, head side, nape and upperparts olive; wings blackish, two olive-buff, buff or ochre wingbars; tail dusky, notched; throat pale yellow, breast and flanks olive with ochre tinge or wash, belly and undertail-coverts buffy yellow; plumage paler and duller overall when worn; iris dark; bill broad, upper mandible black, lower mandible orange-yellow; legs blackish. Sexes similar. Juvenile is similar to adult, but wingbars brighter ochre, margins of lesser coverts edged ochre-buff. Voice. Call a sharp and repeated "pwit", shriller than call of *Empidonax atriceps*; also a typical "pip pip pip" call. Song a piercing high, thin "peeeeyit" or "peeeeyeeet", first syllable accented.
Habitat. Broken canopy of montane oak (*Quercus*) forest or tall second growth, especially near streams, treefall gaps and forest borders; 2200-3000 m.
Food and Feeding. Insects, including hymenopterans, dipterans, lepidopterans, coleopterans. Usually solitary, sometimes with mixed flocks. Searches for prey from exposed perch 6-12 m up, usually at forest edge; upright posture. Captures prey in short aerial sallies, often returning to same perch; frequently shivers tail upon alighting.
Breeding. Mar. Nest a bulky cup constructed primarily of moss, saddled on slender horizontal limb high in canopy near forest edge. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Uncommon to rare, and local. More or less confined to the Irazú-Turrialba massif of Cordillera Central and Cordillera de Talamanca, in Costa Rica; very few records from Panama. Highland forests in this species' range have been extensively destroyed by burning, logging and agricultural conversion; 50% of Costa Rica's forests have been lost since 1940, and current deforestation rate of c. 3% annually means that forests will soon survive only in protected areas.
Bibliography. Anon. (1998a), Collar *et al.* (1994), Cory & Hellmayr (1927), Delgado (1985), Eisenmann (1955), Ridgely & Gwynne (1989), Ridgway (1907), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

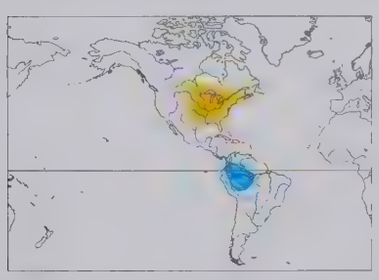
248. **Western Wood-pewee**

Contopus sordidulus

French: Pioui de l'Ouest **German**: Westlicher Waldschnäppertyrann **Spanish**: Pibí Occidental
Other common names: Western Pewee

Taxonomy. *Contopus sordidulus* P. L. Sclater, 1859, Orizaba, Mexico.
Thought by some possibly to form a superspecies with *C. virens* and *C. cinereus*; has been considered conspecific with former. Geographical variation subtle, size increasing to N, colour becoming richer in moist environments such as Pacific NW. Proposed races *siccicola* (described from Idaho, USA) and *amplus* (Montana, USA) merged with *veliei*, and *griscomi* (Guerrero, in Mexico) with nominate. Four subspecies recognized.
Subspecies and Distribution.
C. s. saturatus Bishop, 1900 - breeds SE Alaska and NW & W Canada S in USA to W Oregon; winters N South America (probably mainly Colombia and Venezuela).
C. s. veliei Coues, 1866 - breeds E Alaska S through interior mainly to N Mexico, E in USA to N & W Great Plains states and S to W Texas; winters probably South America (S possibly to Peru, Bolivia and N Argentina).
C. s. peninsulae Brewster, 1891 - breeds W Mexico (S Baja California); winters probably NW South America.
C. s. sordidulus P. L. Sclater, 1859 - breeds highlands of Mexico S at least to Honduras, possibly to NC Nicaragua and Costa Rica; winters S to Colombia, Ecuador and Peru.

Descriptive notes. 14-16 cm; 12-14 g. Nominate race has peaked crown dark greyish-brown, faint paler lores, indistinct thin eyering (sometimes lacking); head side, nape and upperparts uniform greyish-brown; wings dusky, greyish tips on wing-coverts (two indistinct narrow wingbars), greyish margins on secondaries and tertials; long primary projection; tail dusky; throat pale grey to whitish, breast and flanks dull grey (darker "vest"), belly paler, tinged yellow, undertail-coverts whitish with darker grey-brown centres; underwing-coverts greyish; iris dark brown; upper mandible black, lower mandible black with pale orange at base or all dark; legs blackish. Distinguished with difficulty from *C. virens* by on average darker and browner plumage, darker underwing and undertail-coverts, less pale colour at base of lower mandible. Sexes similar, female slightly smaller than male. Juvenile resembles adult, but browner above, slightly darker below, wingbars broader and buffy. Race *saturatus* is darker and more olive above than nominate, blackish on crown, yellower on throat and belly; *veliei* is greyer, with little or no yellow tinge below; *peninsulae* is paler, with narrow grey breastband, broader margins on remiges, shorter wing and tail, longer bill. Voice. Song, typically by territorial male, a harsh burry and descending "pee-er", "phreeer", "peweer" or "brreeu", sometimes followed by rapid rolled "chu-i-lit". Male dawn song "tswee tee



teet" or "pee-pip-pip-pip" alternated with "pee-er" songs. Also a "bzew" call, perhaps only at night; infrequent "chip" or "pip" by both sexes when alarmed, and rapid twitter call.
Habitat. Variety of semi-open deciduous, coniferous and mixed woodland habitats, forest edge and riparian vegetation; breeds in pine-oak (*Pinus-Quercus*) and pine forests and other semi-open woodlands in Mexico. During migration, also in treeless desert. Winters in mature and secondary tropical forest, montane forest and forest borders. Sea-level to at least 3000 m; 500-3000 m in Mexico; in non-breeding range to 1000 m in Venezuela, and recorded at 2600 m in Colombia (Bogotá savanna).
Food and Feeding. Insects, rarely also spiders; fruit taken rarely. Insects include dipterans, hymenopterans, coleopterans, lepidopterans (adults, rarely caterpillars), damselflies and dragonflies (Odonata), mayflies (Ephemeroptera), neuropterans, termites (Isoptera), bugs (Hemiptera); average prey length 6·9 mm. Searches for prey from dead branch or other exposed perch high in canopy, near small opening in forest; perches upright. Makes short or long sallies to hawk insects from air or glean prey from foliage or ground, returning to same or nearby perch; quivers wings upon landing.
Breeding. Early May to late Aug. Compact nest cup made of woven grass, plant fibres, bark, plant down, feathers, animal hair, moss, insect puparia and bud scales, bound together by spiderweb, lined with fine grass and animal hair, average external diameter 8·5 cm, height 6·6 cm, internal diameter 4·8 cm, depth 3·4 cm; saddled in fork of horizontal branch near ground to more than 25 m up, nest trees include various Populus species (e.g. *P. fremontii*, *P. trichocarpa*, *P. tremuloides*), black walnut (*Juglans nigra*), sycamore (*Platanus racemosa*), *Ailanthus altissima*, willow (*Salix*), valley oak (*Quercus lobata*). Clutch 2-4 eggs, usually 3; incubation period 14-15 days; fledging period 14-18 days, usually 16 days. Average success variable; in USA, 82% of nests in ponderosa pine (*Pinus ponderosa*) and riparian forest in Colorado fledged more than one young, compared with 46% in riparian forest in N California. Probably capable of breeding at 1 year. Longevity record 6 years 1 month.
Movements. Medium-distance to long-distance migrant, wintering in South America. Departs breeding grounds mainly Aug-Sept, passing through Costa Rica late Jul to mid-Nov; leaves wintering grounds in Ecuador as late as Mar, passes N through Venezuela Feb-Apr, through Costa Rica late Mar to late May; arrives on breeding grounds in Mexico mid-Mar to early Jun, in S USA (Texas) by mid-Apr to late May. Vagrants recorded in E half of USA, also from Cuba and Jamaica.
Status and Conservation. Not globally threatened. Fairly common to uncommon. Global population estimated at 9,700,000 individuals. Survey data for Canada and USA show that this species decreased by 1·5% annually between 1966 and 1994, with highest decreases in British Columbia, California, Oregon, Arizona and New Mexico; declines possibly due to destruction of riparian habitats by grazing, agriculture and urbanization; loss and alteration of wooded habitats in non-breeding range (e.g. Andean foothill forests) may also have a negative effect. In view of the species' use of edge and semi-open habitats, however, reasons for the overall decline remain unclear. May benefit in some areas from forest fragmentation; numbers increased in places where forest opened up by fires, management or natural tree diseases.
Bibliography. Anon. (1998a), Arendt (1992), Armstrong (1983), Baicich & Harrison (1997), Beal (1912), Beaver & Baldwin (1975), Bemis (1996), Bemis & Rising (1999), Bent (1942), Binford (1989), Campbell *et al.* (1997), Chace *et al.* (1997), Clapp *et al.* (1983), Cory & Hellmayr (1927), Curson *et al.* (1996), DeGraaf & Rappole (1995), Fitzpatrick (1980a, 1980c), Fjeldså & Krabbe (1990), Gómez & Aguilar (1998), Harrison, C. 249. **Eastern Wood-pewee**

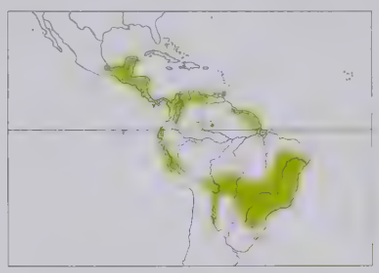
Contopus virens

French: Pioui de l'Est **German**: Östlicher Waldschnäppertyrann **Spanish**: Pibí Oriental

Taxonomy. [*Muscicapa*] *virens* Linnaeus, 1766, Carolina, USA.
Thought by some possibly to form a superspecies with *C. sordidulus* and *C. cinereus*; has been considered conspecific with former. Monotypic.
Distribution. Breeds SE Canada (Saskatchewan E to Maritime Provinces) and S in USA to SC Texas, Gulf Coast states and C Florida. Winters mainly from Colombia and Venezuela S to N Bolivia and W Brazil, casually as far N as Costa Rica.



Descriptive notes. 13·5-15 cm; 14g. Has peaked crown dark greyish-brown to greyish-olive, faintly paler lores, indistinct thin eyering (sometimes absent); head sides, nape and upperparts uniform greyish-brown or greyish-olive; wings and tail dusky, pale grey tips of wing-coverts (two distinct narrow wingbars), greyish margins of secondaries and tertials; long primary projection; throat pale grey to whitish in centre, breast and flanks dull grey (forming darker "vest"), belly yellow-tinged whitish, undertail-coverts whitish with pale grey centres, sometimes tinged yellow; underwing-coverts whitish; iris dark brown; upper mandible black, lower mandible pale orange with dark tip; legs blackish. Distinguished with difficulty from *C. sordidulus* by being on average slightly more olive above, paler below, especially on throat and belly, paler underwing-coverts, more extensive pale orange on lower mandible. Sexes similar, female slightly smaller than male. Juvenile has browner upperparts than adult, broader buffy wingbars, slightly darker below. VOICE. Song, by male, consists of slurred "pee-ah-wee", second note lower, and alternating "peeeur", "wee-oo" or "wee-ur", often in different combinations; sometimes followed by rapid rolled "hew-di-lit". Dawn song similar, with "ah di dee" added. Also short "chip", twittering flight songs, and shrill "pe-e-e-e-e" when disturbed.
Habitat. Breeds in variety of coniferous and deciduous forest habitats, often near clearings or edges; often near riparian areas in Midwest USA, less frequently near streams in E. Variety of forest and successional habitats during migration, including scrub in Yucatán Peninsula, cloudforest in S Mexico (Chiapas), dry to moist forest in Panama. Winters in forested habitats, including gallery forest, secondary growth, shrubby areas; in Peru, in successional forest, treefall gaps, edges of flooded forest, *Cecropia* and young *Ficus* stands; in gallery forest with many wild cashews (*Anacardium*) in Venezuela. Sea-level to 1500 m, but on passage up to 2850 m in Colombia; usually winters below 1300 m.
Food and Feeding. Insects less than 15 mm long, including dipterans, homopteran bugs, lepidopterans, hymenopterans, coleopterans; rarely, fruit. Searches for prey from dead branch or other perch in subcanopy or canopy; perches upright. Sallies to hawk insects from air or to glean prey from foliage or ground, then continuing on to new perch, occasionally returning to original perch.
Breeding. May-Sept. Nest a shallow woven cup of grass, bark strips, twigs, roots, moss, pine needles and leaves, outside covered with lichen, lined with animal hair, grass, moss, lichen and plant fibres, average external diameter 7·5-8·5 cm, height 3-4·5 cm, internal diameter 4·5-5 cm, depth 1·5-3 cm; placed 5-20 m up on outer horizontal branch. Clutch 2-4 eggs, usually 3; incubation probably 12-13 days; fledging probably 16-18 days. Breeds at 1 year. Longevity record greater than 7 years.
Movements. Long-distance migrant, wintering in South America. Migrates at night. Departs breeding grounds mid-Aug to Sept, passing through Mexico Aug-Nov; some cross Caribbean. Leaves wintering areas Apr, migrating via similar routes as in autumn (or perhaps on more W route through Mexico), passing through Mexico late Mar to early Jun; arrival in extreme S USA first half Apr, in most of breeding range by mid-May. Vagrants recorded in W USA, Barbados, Bermuda, and NE Canada.
Status and Conservation. Not globally threatened. Fairly common to common; common over much of breeding range. Global population estimated at 6,000,000 individuals. Locally common migrant in Venezuela. Survey data indicate significant population decline of 35·6% between 1965 and 1993 (13·4% from 1984 to 1993), although increases noted in some areas; declines stronger in C USA than in E. Loss and alteration of wooded habitats in both breeding and wintering ranges may have a negative effect; nevertheless, given the species' use of edge and semi-open habitats, and apparent tolerance of forest fragmentation, reasons for the overall decline remain unclear; heavy browsing by artificially high numbers of white-tailed deer (*Odocoileus virginianus*) implicated in an experimental study.

250. **Tropical Pewee**

Contopus cinereus

French: Moucherolle cendré **Spanish**: Pibí Tropical
German: Südlicher Waldschnäppertyrann

Taxonomy. *Platyrhynchus cinereus* Spix, 1825, "in sylvis flum. Amazonum"; error = Rio de Janeiro, Brazil.
Thought by some possibly to form a superspecies with *C. sordidulus* and *C. virens*. Formerly included race *canescens* of *C. nigrescens*. Races possibly represent more than one species; nominate differs from others in plumage, and *punensis* differs vocally. Eight subspecies recognized.
Subspecies and Distribution.
C. c. brachytarsus (P. L. Sclater, 1859) - S Mexico (from N Oaxaca, S Veracruz and Yucatán, including Cozumel I) S to Panama (W of Darién Gap).
C. c. rhizophorus (Dwight & Griscom, 1924) - Guanacaste, in NW Costa Rica.
C. c. aithalodes Wetmore, 1957 - Coiba I, off S Panama.
C. c. bogotensis (Bonaparte, 1850) - N & E Colombia, N Venezuela, Trinidad and NW Brazil.
C. c. surinamensis F. P. Penard & A. P. Penard, 1910 - SE Venezuela, the Guianas and NE Brazil.
C. c. punensis Lawrence, 1869 - W Ecuador and W & C Peru.
C. c. pallescens (Hellmayr, 1927) - SC & E Brazil S to NE Paraguay, Bolivia and NW Argentina.
C. c. cinereus (Spix, 1825) - SE Paraguay, SE Brazil and NE Argentina.

Descriptive notes. 13-14·5 cm; 12-12·5 g. Nominate race has peaked crown with slight crest; is dark sooty grey above and below; two indistinct paler wingbars, grey throat, tiny area of white on central belly and undertail-coverts; iris dark; upper mandible black, lower mandible yellowish, rarely with dark tip; legs blackish. Sexes similar. Juvenile is browner above than adult, head and back feathers narrowly fringed whitish, wingbars and margins of remiges yellowish to bright buff, paler underparts. Races vary in plumage and size, nominate distinctive, others rather similar with paler lores, brownish-grey or olive-grey above, usually stronger wingbars, whitish throat sometimes tinged yellow, breast and sides washed grey or olive-grey, whitish belly and undertail-coverts sometimes tinged pale yellow: *aithalodes* has greyer throat, darker breastband, juvenile with buff feather fringes above; *brachytarsus* resembles previous, but darker on crown; *rhizophorus* is like last, but no olive tinge above, grey below with yellow tinge restricted to flanks; *surinamensis* is paler grey overall, crown contrasts little with back, juvenile with cinnamon fringes above; *pallescens* differs from previous in darker blackish-grey crown; *bogotensis* is slightly darker overall, also larger; *punensis* is darker, has more contrasting dark crown and darker grey back, is also larger and larger-billed than previous. VOICE. Calls vary geographically: in Venezuela and most of range a short trilled "seerip", "tre'e'e'e" or "tir'r'r'ip"; in E Brazil a more typical "pip-pip-pip" or "bit-bit-bit"; metallic "peet" or "fweet" in Costa Rica; trilled "ti-i-i-i-il" or "tree-ee-ee-eet" in Mexico. Song, too, may vary geographically: a repeated "tzee-zée" in Andes; upslurred "psee-eep" or "pee-eep" in Mexico; clear "pee, pidit" in W Ecuador; "wítjew" in E Brazil. Dawn song in Mexico upslurred "s-iep" or "w-iep", repeated every 2-3 seconds; in Costa Rica "wee tweet weet" interspersed with more musical "we-ye" notes.
Habitat. Borders of dry to moist forest, woodland, gallery forest, and plantations; shrubby clearings, dry bushy slopes with *Carica* and balsa trees, and locally mangroves. Sea-level to 1200 m in Mexico; up to 1500 m in much of South America, to 1900 m in Venezuela, occasionally to 2600 m in Andes.
Food and Feeding. Insects, including small hymenopterans, coleopterans, lepidopterans, dipterans. Searches from exposed perch at low to middle levels in open areas or along forest border; sallies for prey, often returning to same perch.
Breeding. Mar-Jun in Costa Rica, Mar and May-Jul in Trinidad; nests (two) found in Oct and Nov in Argentina. Male display involves squatting, jumping, and flicking of wings and tail, reminiscent of *Pipra* manakins. Nest a broad and neat shallow cup made of grey lichens, tendrils, seed down, weed stems and green moss, bound with spiderweb, placed 2-14 m up on exposed horizontal branch or upright fork in shrub or tree. Clutch 2-3 eggs; in Costa Rica, incubation by female, fed by male, period 15-16 days; no information on fledging period.
Movements. Mainly resident; migratory in extreme N and extreme S. In Mexico, most birds breeding from Chiapas to S Veracruz move S in winter, Sept-Feb; *pallescens* moves N during austral winter.
Status and Conservation. Not globally threatened. Uncommon to locally common. Occurs in many national parks and other protected areas throughout its large range. Adaptable; tolerant of converted and secondary habitats.
Bibliography. dos Anjos (1990), Anon. 251. Cuban Pewee

Contopus caribaeus

French: Moucherolle tête-fou **German**: Kubaschnäppertyrann **Spanish**: Pibí Cubano
Other common names: Greater Antillean Pewee (if lumped with *C. pallidus* and *C. hispaniolensis*)

Taxonomy. *Muscipeta caribaea* d'Orbigny, 1839, Cuba.
Formerly treated as conspecific with *C. pallidus* and *C. hispaniolensis*. Four subspecies recognized.
Subspecies and Distribution.
C. c. bahamensis (H. Bryant, 1859) - Bahamas.
C. c. caribaeus (d'Orbigny, 1839) - Cuba and I of Pines.
C. c. morenoi Burleigh & Duvall, 1948 - mangroves on S coast of Cuba and nearby cays.
C. c. nerlyi Garrido, 1978 - Archipiélago de los Jardines de la Reina and nearby islands, off S Cuba.

Descriptive notes. 15-16·5 cm. Nominate race has dark olive-grey crown, tufted crest; slightly paler loral area, whitish crescent around rear of eye (extending to slight tip posteriorly); ear-coverts, nape and upperparts olive-brown; wings dusky brown, median and greater wing-coverts tipped pale brown to whitish-grey (two thin indistinct wingbars), outer secondaries and tertials edged whitish; short primary projection; tail dusky; throat pale grey, slightly tinged buff; breast beige-grey, washed olive on side of upper breast, belly and undertail-coverts more buffy mustard-yellow; iris dark; bill broad, flat, upper mandible black, lower mandible orange-yellow; legs black. Sexes similar. Juvenile resembles adult, but wingbars broader and buffy white, lower mandible paler. Race *bahamensis* is duller and greyer than nominate, paler above, less contrast between crown and back, paler below, only slight yellow tinge on belly; *nerlyi* is intermediate between previous and nominate, largely buffish below; *morenoi* resembles last. Voice. Generally rather vocal, often throughout day. Song a prolonged descending "weeeooooo". Call a repeated "weet" or "dee"; also softer "dep" or "vi-vi" note, reminiscent of *Myiarchus sagrae*. Dawn song (nominate race) a high squeaky whistle, "eeah, ooweeah", usually given sequentially; in Bahamas (*bahamensis*), a "dee-dee" phrase is added to the "eeah, ooweeah" series.
Habitat. Broadleaf and pine (*Pinus*) forests, forest edge, swamps, mangroves, brushy scrub, and tree plantations. Sea-level to 1800 m; rarer at high elevations.
Food and Feeding. Mainly insects; some fruit. Searches from low perch; sallies out to capture prey in the air (sometimes with loud snap of bill), often returning to same perch; shakes or flicks tail upon landing.
Breeding. Feb-Mar in Bahamas, Mar-Jun in Cuba. Nest a cup made of fine rootlets and hair, covered by lichen and moss, typically placed in fork of tree or shrub or on branch. Clutch 2-4 eggs; no other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Common. Widespread from coast to moderate elevations. Occurs in Güira National Park, in Cuba.
Bibliography. Anon. (1998a, 2002f), Barbour (1943), Bond (1985), Brudenell-Bruce (1975), Buden (1987b), Cory & Hellmayr (1927), Emlen (1977), Faaborg (1985), Garrido (1978), Garrido & Kirkconnell (2000), Gundlach (1873), Kirwan & Kirkconnell (2000), Raffaele *et al.* (1998, 2003), Reynard *et al.* (1993), Ridgway (1907), Socarrás (2001), Stotz *et al.* (1996), White (1998).

252. Jamaican Pewee

Contopus pallidus

French: Moucherolle de Jamaïque **German**: Jamaikaschnäppertyrann **Spanish**: Pibí Jamaicano
Other common names: Greater Antillean Pewee (if lumped with *C. caribaeus* and *C. hispaniolensis*)

Taxonomy. *Myiobius pallidus* Gosse, 1847, Jamaica.
Formerly treated as conspecific with *C. caribaeus* and *C. hispaniolensis*. Monotypic.
Distribution. Jamaica.

Descriptive notes. 15 cm. Has dark olive-brown head and upperparts, darkest on crown; wings dark brown, indistinct narrow buff wingbars (sometimes absent); long tail dusky brown, slightly notched; buff mixed with grey below, throat greyer, breast and sides washed with olive, undertail-coverts buffier; iris dark brown; bill broad, upper mandible black, lower mandible orange-yellow; legs blackish-brown. Sexes similar. Juvenile is greyer on underparts, paler chest, paler lower mandible, cinnamon wingbars. Voice. Call a plaintive "pee", rarely "pee-wee". Song a rising and then falling "oéeoh". Dawn song two alternating phrases, "paléet, weeléah".
Habitat. Forest, less often at edge, in openings beneath canopy. Mid-elevations to montane, to 2000 m.
Food and Feeding. Insects. Searches in erect posture from exposed perch 2-9 m up; makes long horizontal sallies to capture prey from the air, returning to same or new perch; flicks tail upon landing.
Breeding. Apr-Jun; possibly nests twice yearly. Nest a cup made of finely woven plant fibres, grass and Spanish moss (*Tillandsia*), placed in fork of tree. No other information.
Movements. Descends to lower elevations, and occasionally to lowlands, during non-breeding season.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA. Common and widespread. In Jamaica, 75% of original forest cover already cleared, and remaining forest largely second growth. Undisturbed forest survives only on high steep mountain slopes, some of which protected in the Blue Mountain and John Crow National Park, but hunting and habitat destruction continue because of lack of funds for protection and management. Resurgence in coffee cultivation during last 20 years led to clearance of much second growth; other problems include hurricane damage, widespread pesticide use, planting with pines (*Pinus*), timber removal, deliberate fires, and continuing conversion for small-scale farming and urbanization.
Bibliography. Anon. (1994, 1998a), Bond (1985), Cory & Hellmayr (1927), Downer & Sutton (1990), Faaborg (1985), Raffaele *et al.* (1998, 2003), Reynard *et al.* (1993), Ridgway (1907), Stotz *et al.* (1996).

253. Hispaniolan Pewee

Contopus hispaniolensis

French: Moucherolle d'Hispaniola **Spanish**: Pibí de la Española
German: Hispaniolaschnäppertyrann
Other common names: Greater Antillean Pewee (if lumped with *C. caribaeus* and *C. pallidus*)

Taxonomy. *Tyrannula carriboea* [sic] (var. *hispaniolensis*) H. Bryant, 1867, Santo Domingo, Dominican Republic, Hispaniola.
Formerly treated as conspecific with *C. caribaeus* and *C. pallidus*. Two subspecies recognized.
Subspecies and Distribution.
C. h. hispaniolensis (H. Bryant, 1867) - Hispaniola.
C. h. tacitus (Wetmore, 1928) - Gonâve I, off W Haiti.

Descriptive notes. 15-16 cm. Head and upperparts are greyish-olive, darkest on crown; wings and tail dusky, inconspicuous pale wingbars (often absent); throat grey, olive-brown wash across breast; belly and undertail-coverts yellowish-buff mixed with grey; iris dark; bill broad, blackish, lower mandible pale at base; legs blackish. Sexes alike. Juvenile has pale feather fringes on crown, back and wing-coverts. Race *tacitus* similar to nominate. Voice. Call "purr, pip-pip-pip-pip". Dawn song a loud, rapid series of paired notes rising in pitch, "shurr, pet-pit, pit-pit, peet-peet".
Habitat. Various wooded habitats, including pine (*Pinus*) and broadleaf forests, shade coffee plantations, orchards, forest edges. Sea-level to at least 1800 m.
Food and Feeding. Insects; also small fruits. Searches from low perch, sallying out to capture insects in the air; flicks tail upon landing. Reported as joining mixed-species flocks in pine forests.
Breeding. May-Jun. Nest constructed by female, a cup of rootlets, lichen and moss, placed 3-5 m up in fork of twig. Clutch 2-4 eggs; incubation by female, chicks fed by both parents; no other information.
Movements. Resident. Vagrant on Mona I, between Hispaniola and Puerto Rico; recorded in Bahamas (Providenciales) in Sept after hurricane.
Status and Conservation. Not globally threatened. Restricted-range species: present in Hispaniola EBA. Common and widespread. Haiti is one of the world's most environmentally degraded countries, with remaining forests covering less than 1·5% of its surface area, while c. 10% of forests remain in Dominican Republic; forests continue to be destroyed by logging, slash-and-burn agriculture, charcoal production, and replacement with pine plantations. Only two small national parks exist in Haiti, and c. 22 protected areas (and 15 new areas proposed) covering c. 16% of the area of Dominican Republic, but lack of funds for protection and management threaten their long-term survival.
Bibliography. Anon. (1998a), Bond (1928a), Cory & Hellmayr (1927), Dod (1987), Faaborg (1985), Keith *et al.* (2003), Raffaele *et al.* (1998, 2003), Reynard *et al.* (1993), Rimmer *et al.* (2003), Ridgway (1907), Stotz *et al.* (1996), Wetmore & Swales (1931).

254. Lesser Antillean Pewee

Contopus latirostris

French: Moucherolle gobemouche **Spanish**: Pibí Puertorriqueño
German: Kleinantillen-Schnäppertyrann
Other common names: Puerto Rican Pewee (*blancoi*); St Lucia Pewee (*latirostris*)

Taxonomy. *Myiobius latirostris* J. Verreaux, 1866, St Lucia, Lesser Antilles.
Races sometimes treated as three separate species; nominate, *blancoi* and *brunneicapillus* have occasionally been referred to as, respectively, *oberi*, *portoricensis* and *latirostris*, presumably in error. Three subspecies recognized.
Subspecies and Distribution.
C. l. blancoi (Cabanis, 1875) - Puerto Rico.
C. l. brunneicapillus (Lawrence, 1878) - Guadeloupe, Dominica and Martinique.
C. l. latirostris (J. Verreaux, 1866) - St Lucia.

Descriptive notes. 15 cm. Nominate race has head and upperparts dark olive-brown, paler lores; wings and tail blackish-brown; chin pale, throat and entire underparts rufous-cinnamon; iris dark; bill broad and flat, upper mandible black, lower mandible pale at base; legs black. Sexes alike. Juvenile has pale feather fringes above, also broad cinnamon to brown wingbars, perhaps paler and greyer throat and breast. Race *blancoi* has throat and breast dull ochre tinged greyish-olive, becoming buffier on undertail-coverts; *brunneicapillus* is palest below, pale yellow-brown throat shading to ochre-buff on breast and undertail-coverts. Voice. Song a rising "pree-e-e"; on Puerto Rico described as high-pitched trill rising up the scale (like water filling a glass). Dawn song a repetitive trill. Call a repeated "peet-peet-peet".
Habitat. Mainly montane forest; less frequently drier forest, scrub and mangroves at lower elevations.
Food and Feeding. Insects. Searches from perch low to ground and usually in open area beneath forest canopy; sits erect; sallies from perch to capture prey.
Breeding. Mar-Jun on Puerto Rico and May-Jun on St Lucia. Nest a cup made of leaves, lichen and moss, placed on branch or twig of tree or bush. Clutch 2 eggs; no other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA and Lesser Antilles EBA. Fairly common, but rather local. In 1978, Puerto Rico was covered by 1% virgin forest, 5% shaded coffee plantations, and c. 32% second growth due to natural succession following its conversion from an agricultural country to a more industrial one; over 20 protected areas exist on the island, and private lands also contain large

tracts of mature second growth. The Lesser Antilles have suffered large-scale destruction of forests through agricultural and tourist development, with less destruction on the mountainous islands with inaccessible areas; several reserves exist, but most are relatively small.
Bibliography. Anon. (1998a), Benito-Espinal & Hautcastel (1988), Biaggi (1983), Bond (1985), Cory & Hellmayr (1927), Faaborg (1985), Keith (1997), Raffaele (1989), Raffaele *et al.* (1998, 2003), Ridgway (1907), Tossas & Delannoy (2001).

255. **White-throated Pewee**

Contopus albogularis

French: Moucherolle à bavette blanche **Spanish**: Pibí Gorgiblanco
German: Weißkehl-Schnäppertyrann

Taxonomy. *Myiochanes albogularis* Berlioz, 1962, Maripasoula, Maroni Basin, French Guiana. Monotypic.
Distribution. Locally in Surinam, French Guiana and extreme NE Brazil (Amapá).

Descriptive notes. 13 cm. Small, dark pewee. Has crown dark blackish-grey, slightly paler grey lores, narrow indistinct whitish eyering (more distinct at rear); head side, nape and upperparts uniform dark sooty grey; wings blackish-brown, tail blackish; throat white, underparts sooty grey; iris dark; bill broad, flat, upper mandible black, lower mandible yellow; legs black. Differs from *C. nigrescens* in having white throat. Sexes similar. Juvenile undescribed. Voice. Call "pip-pip-pip".
Habitat. Edge of humid forest and adjacent small clearings; 400-700 m.
Food and Feeding. Insects. Searches for prey from high exposed snag or other perch; sits erect; sallies out to capture aerial prey, returns to same perch repeatedly, shivers tail upon landing.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon and very local. In Surinam, common in Brownsberg Nature Park, particularly along roads on the plateau; rare in Lely Gebergte.
Bibliography. Cracraft (1985), Forrester (1993), Haverschmidt & Mees (1994), Meyer de Schauensee (1982), Novaes (1978a), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992).

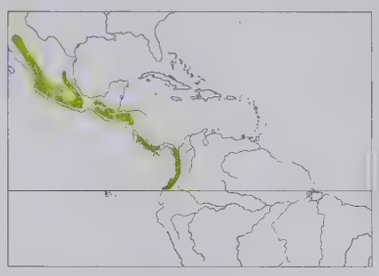
256. **Blackish Pewee**

Contopus nigrescens

French: Moucherolle noirâtre **German**: Dunkelschnäppertyrann **Spanish**: Pibí Negruzco

Taxonomy. *Myiochanes nigrescens* P. L. Sclater and Salvin, 1880, Sarayacu, Pastaza, Ecuador. Race *canescens* formerly included in *C. cinereus*. Two subspecies recognized.
Subspecies and Distribution.
C. n. nigrescens (P. L. Sclater & Salvin, 1880) - locally on E slope of Andes in Ecuador and N & S Peru; possibly also extreme S Colombia.
C. n. canescens (Chapman, 1926) - disjunctly in S Guyana and E Amazonian Brazil.

Descriptive notes. 13 cm. Small, all-dark pewee. Has dark blackish-grey crown, slightly paler grey lores, narrow indistinct whitish eyering (more distinct at rear); rest of head, nape and upperparts uniform dark sooty-grey; wings blackish-brown, tail blackish; sooty grey below, slightly paler on throat; iris dark; bill broad, flat, upper mandible black, lower mandible yellow; legs black. Sexes similar. Juvenile is like adult, but with narrow whitish wingbars. Race *canescens* has slightly less dark crown, back, throat and upper breast than nominate. Voice. "Pip" or "peep" call, sometimes doubled. Male song a snappy, burry "chí-bew", repeated at intervals of 3-4 seconds, less frequently a hoarse "zur-zur-zur-zur-zur".
Habitat. High canopy and margins of humid forest in foothills, often along streams or near natural forest gaps. At 400-900 m in Ecuador; mainly 800-1050 m in Peru, but 400-1200 in Madre de Dios and recorded to 3000 m at Machu Picchu.
Food and Feeding. Insects. Usually in pairs in Ecuador. Sits erect on high perch in canopy; sallies to catch aerial prey, often returning repeatedly to same perch. Often found in same area, even on same perch, for many days.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to locally fairly common; probably often overlooked. Fairly common near Taisha (Morona-Santiago) and near Campococha, in Ecuador; rare in San Martín, Huánuco and Amazonas, in Peru.
Bibliography. Blake (1950), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Walker (2002).



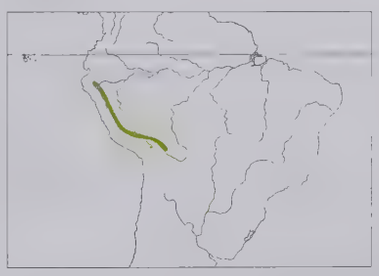
Genus *MITREPHANES* Coues, 1882

257. **Tufted Flycatcher**

Mitrephanes phaeocercus

French: Moucherolle huppé **Spanish**: Mosquero Moñudo Común
German: Gelbbauch-Schnäppertyrann
Other common names: Common Tufted Flycatcher

Taxonomy. *Mitrephorus phaeocercus* P. L. Sclater, 1859, Córdoba, Veracruz, Mexico.
Closely related to *M. olivaceus*, and formerly considered conspecific. Other described races are *burleighi* (Mexican mountains from C Jalisco and W Zacatecas S to W Oaxaca) and *nicaraguae* (Chiapas, in Mexico, S to Nicaragua), both merged with nominate; *vividus* (C & E Panama), merged with *aurantiiventris*; and *eminulus* (Cerro Pirre, in E Panama, and adjoining Chocó, in Colombia), merged with *berlepschi*. Four subspecies recognized.
Subspecies and Distribution.
M. p. tenuirostris Brewster, 1888 - W Mexico, from Sonora and Chihuahua S to Jalisco.
M. p. phaeocercus (P. L. Sclater, 1859) - mountains of E & C Mexico S to El Salvador and NE Nicaragua.
M. p. aurantiiventris (Lawrence, 1865) - Costa Rica and Panama.
M. p. berlepschi Hartert, 1902 - extreme E Panama (Cerro Pirre) and NW Colombia S to NW Ecuador.



Descriptive notes. 12-13·5 cm; 8·5 g. Nominate race has brown-tinged olive crown, distinct pointed crest; pale loral spot and thin buff-white eyering set against cinnamon face and side of head, contrasted by narrow brownish-olive stripe down nape; upperparts brownish, tinged olive; wings dusky, two buff wingbars, buff margins of secondaries, whitish or pale yellow tertial margins; tail dusky; throat and breast bright ochre to cinnamon, belly ochre-yellow; iris dark; upper mandible black, lower mandible orange-yellow; legs blackish. Sexes similar. Juvenile has crown dark brown, cinnamon-buff feather fringes on crown and upperparts to tail-coverts, perhaps broader cinnamon-orange wingbars. Race *tenuirostris* is paler and duller overall than nominate; *berlepschi* has darker olive crown, yellowish lores, olive back, olive margins of wing-coverts and secondaries, tertials edged more whitish, olive breast with very slight ochre tinge, bright yellow belly; *aurantiiventris* is intermediate, has upperparts and wing margins similar to previous but olive on back perhaps not quite so bright, underparts similar to nominate but perhaps more ochre than cinnamon. Voice. Song single or repeated "tchwee" or "turee" notes; also a "pseeu", "seeeu" or "seer" during breeding season. Call "pik" or "beek". Dawn song in Costa Rica described as a rapid series of high notes, "bip-bip-bip-dididi-up-bip-bip-bibibiseer".
Habitat. Borders, treefall gaps, clearings and broken canopy of montane forests, including pine (*Pinus*), broadleaf and second-growth forests, as well as plantations; also more arid semi-open areas and riparian zones in winter. At 700-3500 m; in Costa Rica most abundant at 1200-2150 m, rare down to 450 m; mainly in foothills, 100-1200 m, in South America.
Food and Feeding. Insects. Usually found in pairs. Sits upright on exposed perch in low to upper levels of forest; sallies to capture prey, often returning to same perch, often shivers tail upon landing.
Breeding. Apr-Jun in Costa Rica and Feb in Colombia (Chocó). Nest a shallow cup of dark rootlets and green moss, liverworts and lichens, lined with foliaceous lichens, placed 4-27 m up saddled in dangling vine, or on upright or horizontal branch hidden in epiphytic vegetation. Clutch 2 eggs; no other information.
Movements. Resident. Altitudinal migrant in parts of Mexico N of isthmus; locally, descends to Sinaloa and Jalisco (NW Mexico) in winter.
Status and Conservation. Not globally threatened. Uncommon to common or fairly common, and local. Fairly common along lower Buenaventura road in Valle, in Colombia; in Ecuador, fairly common near Salto del Tigre bridge over R Guaillabamba, but uncommon at Playa del Oro. Occurs in Rancho Naturalista and Tapantí National Park, in Costa Rica.
Bibliography. Anon. (1998a), Binford (1989), Blake (1958), Cory & Hellmayr (1927), Cracraft (1985), Fleming & Baker (1963), Haffer (1975), Henderson (2002), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Meyer de Schauensee (1982), Monroe (1968), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Salaman (1994), Schaldach (1963), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Wetmore (1941, 1972).

258. **Olive Flycatcher**

Mitrephanes olivaceus

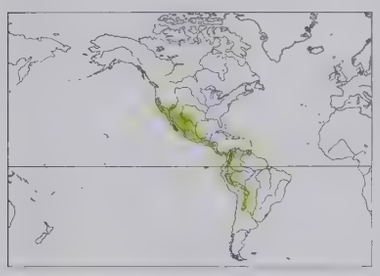
French: Moucherolle olive **Spanish**: Mosquero Moñudo Oliváceo
German: Olivbauch-Schnäppertyrann
Other common names: Olive Tufted Flycatcher

Taxonomy. *Mitrephanes olivaceus* Berlepsch and Stolzmann, 1894, Garita del Sol, Peru.
Closely related to *M. phaeocercus*, and formerly considered conspecific. Monotypic.
Distribution. C Andes of Peru (S from Cerro Chinguela, in Piura) S to NW Bolivia (La Paz, Cochabamba).

Descriptive notes. 13 cm; 8·5 g. Has olive crown, distinct pointed crest; pale loral spot and thin buff-white eyering; face, nape and upperparts olive; wings and tail dusky, two greyish-olive wingbars, faint pale margins of secondaries and tertials; throat, breast and flanks olive, slight ochre tinge on breast, yellower on central belly; iris dark; upper mandible black, lower mandible orange-yellow; legs blackish. Sexes similar. Juvenile undescribed. Voice. No information.
Habitat. Lower and middle levels of montane forest and borders, at 1000-2000 m.
Food and Feeding. Insects. Usually found in pairs; joins mixed-species flocks. Searches in erect posture from exposed perch in low to upper levels of forest; sallies to capture prey, often returning to same perch, shivers tail upon landing.
Breeding. No information.
Movements. No information.
Status and Conservation. Not globally threatened. Rare to uncommon. Poorly known. Uncommon in Machu Picchu Historical Sanctuary and along Shintuya-Paucartambo road (Cuzco), in Peru. Occurs in Madidi National Park, in Bolivia. Range possibly extends N into S Ecuador.
Bibliography. Chapman (1921), Cory & Hellmayr (1927), Davies *et al.* (1994), Hennessey, Herzog & Sagot (2003), Hornbuckle (1999), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001, 2002), Zimmer (1930, 1938).

PLATE 34

inches 3
cm 8



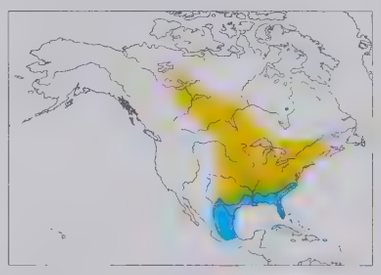
Genus *SAYORNIS* Bonaparte, 1854

259. Black Phoebe

Sayornis nigricans

French: Moucherolle noir **German**: Schwarzkopf-Phoebetyrann **Spanish**: Mosquero Negro
Other common names: White-winged Phoebe (*angustirostris* and *latirostis*)

Taxonomy. *Tyrannula nigricans* Swainson, 1827, Mexico.
Races *latirostis* and *angustirostris* (sometimes synonymized with former) considered a separate species by some authors. Variation clinal: extent of white in wings and on belly generally decreasing N to S; white in wings abruptly increasing S of Isthmus of Panama, thence extent of white, and size, increasing towards S. Six subspecies recognized.
Subspecies and Distribution.
S. n. semiatra (Vigors, 1839) - W USA (S from coastal Oregon, SE to W & C Texas) and W Mexico (Baja California, and S in interior to Isthmus of Tehuantepec).
S. n. nigricans (Swainson, 1827) - NE, C & S Mexico.
S. n. aquatica P. L. Sclater & Salvin, 1859 - Mexico (S of Isthmus of Tehuantepec) S to C Honduras and NW Nicaragua.
S. n. amnicola Bangs, 1902 - Costa Rica and W Panama.
S. n. angustirostris Berlepsch & Stolzmann, 1896 - C & E Panama and N Venezuela S through Andes to C Bolivia.
S. n. latirostris (Cabanis & Heine, 1859) - mountains and foothills of C & S Bolivia and NW Argentina.



Descriptive notes. 15-18 cm; 18 g. Nominate race has head, upperparts and breast sooty black; wings sooty black, paler margins on wing-coverts (two faint wingbars) and on secondaries (whitish panel); tail long, slightly notched, sooty black, outer web of outer rectrix white; belly and undertail-coverts white; iris dark brown; bill black; legs black. Sexes similar, female duller than male. Juvenile has cinnamon fringes on tips of body feathers, buff-cinnamon wingbars. Race *semiatra* is very like nominate, but more white on belly (extending as inverted V-shape into lower breast), more developed white wing and tail markings; *aquatica* has less white than nominate below, restricted to mid-belly, undertail-coverts sometimes sooty; *amnicola* is darkest, with least white on belly, white edging in wings nearly absent, sooty undertail-coverts; *angustirostris* has extensive white edgings on wings, sooty undertail-coverts; *latirostris* is slightly larger than previous, has slightly broader white edging in tail and wings (white occupying half of outer web of tertials), sooty undertail-coverts. Voice. Typical song of two elements, "tee-hee, tee-hoo", alone or in combination, occasionally accompanied by "tieur"; also described as "pidl-ee, pi-ts-lee" and a thin, buzzy "pi-tsee", usually repeated. Dawn song in Jan-Apr (Panama) described as repeated "peep-feebreew". Typical call a rather sharp, downslurred "tsip". Male also has soft, wheezy chatter, used near female during breeding, and trilled series during flight display (Venezuela) described as "t't't't-esk-u,t't't't, esk-u, psip, esk-u, t't't't". A bi-peaked "tweedle-deedle-eek" used while chasing mate and conspecific intruders. Sometimes loud snaps of bill during aggressive encounters.
Habitat. Semi-open and shaded areas near water, including streams, rivers, lakes, coastal cliffs; also riparian vegetation composed of willow (*Salix*), baccharis (*Baccharis*) and mesquite (*Prosopis*) amid desert scrub in Texas. Also uses man-made canals, city parks, cattle troughs, bridges, buildings and other structures for foraging and nesting. Mainly foothill and montane regions with fast-flowing streams from Mexico S to Argentina. Sea-level to 3000 m.
Food and Feeding. Diet mainly insects and other arthropods, including bees and wasps (Hymenoptera), flies (Diptera), termites (Isoptera), beetles (Coleoptera), dragonflies and damselflies (Odonata), true bugs (Hemiptera), spiders (Arachnida), and grasshoppers (Orthoptera). Most frequent prey type varies regionally and seasonally in some areas. Some individuals adapt to capturing small fish, e.g. mosquito fish (*Gambusia affinis*). Small berries, e.g. elderberry (*Sambucus gluaca*), occasionally consumed. Searches from low perch 1-2 m up, occasionally from the ground; typically jerks or wags tail up and down while perched. Pursues prey in direct aerial sallies (usually less than 2 m); most prey captured in flight, but some caught on the ground, buildings, foliage and other substrates; prey usually eaten on the wing, but larger items brought back to a perch and beaten before swallowing. Typically, changes perch after sallies.
Breeding. Breeds Mar-Jun (pairing Jan-Feb) in SW USA (California); Apr-May in N Colombia (Santa Marta), Jul-Oct in Andes, and Sept-Nov in Argentina. Monogamous, rarely polygynous. Male performs nest-site-showing display by hovering vertically and fanning tail for 5-10 seconds. Nest constructed by female, a hemispherical cup made from mud, grass, plant fibres, sometimes animal hair, lined with woven plant fibres, average external height 13 cm, width 10 cm, depth 12·5 cm, internal diameter 6·5 cm, depth 3·1 cm; cemented to vertical wall, near or over water, typically 1-3 m up and 3-7 cm beneath protective ceiling, sites include dirt ledge, large rock, broken tree limb, bridge or other man-made structure; old nests often reused. Clutch 1-6 eggs, usually 3-6; incubation primarily by female, period on average 15-17 days, longer in colder climates; chicks leave nest together after 14-21 days. Estimated lifetime reproductive success 4·13 male fledglings/male, 5·14 female fledglings/female. Sexually mature at 1 year. Lifespan unknown; average yearly survival rates 71·8% (74·9% for females, 67·4% for males); 31·5% of females and 20·6% of males survive to fifth breeding season; 7·4% of females and 2·9% of males survive to tenth breeding season.
Movements. Resident over most of range; some populations at least partially migratory. Movement patterns, timing and routes poorly known, but differ regionally. Populations in extreme S migrate N to Colombia. N birds often leave breeding range in winter months. Altitudinal movements in some areas (e.g. California, Costa Rica), with movement upslope during breeding season and downslope afterwards.
Status and Conservation. Not globally threatened. Fairly common. Global population estimated at 970,000 individuals. Survey data for USA indicate that this species increased by 1·8% annually between 1966 and 1994, but declines noted in many states after 1980. Artificial structures have greatly increased potential nest-site abundance in many areas; on the other hand, continued water diversion and destruction of riparian habitat in arid SW USA reduce amount of suitable habitat. Habitat conversion and pollution of rivers and streams also of concern in other parts of range. This species' large range and its utilization of artificial habitats should, however, ensure its survival.
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bent (1942), Binford (1989), Canevari *et al.* (1991), Contreras (1997), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Fitzpatrick (1980a), Haffer (1975), Henderson (2002), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Kaufman (1996), Lee Jones (2004), Monroe (1968), Narosky & Salvador (1998), de la Peña (1987, 1988), Perry *et al.* (1997), Price *et al.* (1995), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Root (1988), Salaman (1994), Short (1975), Sibley (2000), Skutch (1985), Slud (1964), Small (1994), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Udvardy (1963), Wetmore (1972), Wolf (1997), Zimmer (1930, 1939b).

260. Eastern Phoebe

Sayornis phoebe

French: Moucherolle phébi **German**: Weißbauch-Phoebetyrann **Spanish**: Mosquero Fibí

Taxonomy. [*Muscicapa*] *Phoebe* Latham, 1790, New York, USA.
Monotypic.
Distribution. Breeds mostly in E & C North America, from NW Canada locally E to Maritime Provinces, and from N Great Plains S in USA to C Texas and E to Atlantic coast (S to Georgia). Winters SE and CS USA (locally also NE & SW) S to S Mexico.

Descriptive notes. Male 12·4-16·8 cm, 19·7 g; female 14·2-16·5 cm, 16·9 g. Plumage is greyish-olive above, crown darkest and contrasting with back; wings duskier greyish-olive, feather margins paler, whitish margins of secondaries (sometimes form pale panel on closed wing); throat white, greyish-olive wash across breast, whitish belly and vent sometimes tinged pale yellow; iris dark; bill black; legs black. Sexes similar, female on average slightly smaller than male. Juvenile has pale whitish-buff tips of wing-coverts forming two wingbars. Voice. Common call "chip", "chik" or "piik". Male has two song forms, "fee-bee" and "fee-b-be-bee", both sung in combination, "fee-bee" being more frequent; female rarely sings. Other less frequently used calls include "twee-t", "t-t" or "cheese-it", "t-yooh" or "t-yee", and "t-keet" notes. Also harsh nasal "tree-tree-tree-tree-tree" chatter by male while displaying nest-site to female. Bill-snapping recorded during aggressive encounters.
Habitat. Breeds mainly in forest and forest edge, especially open woodland and frequently deciduous woodland, often near water. Similar habitats during migration, with perhaps stronger preference for riparian vegetation on spring passage. In winter, uses deciduous forest, forest edge, and open and semi-open brushy areas with scattered trees, often near water. Sea-level to 2500 m in winter.
Food and Feeding. Mainly flying insects; occasionally fruit during poor weather in autumn, winter and spring. Diet includes hymenopterans, coleopterans, orthopterans, hemipterans, lepidopterans, dipterans, spiders (Araneae), ticks (Acarina), millipedes (Diplopoda). Recorded also as taking small fish. Searches from low perch less than 10 m up along woodland edge or on lower limbs within closed forest, frequently moving between perches; typically wags tail while perched, by rapidly depressing it, then more slowly raising it with lateral movement (instead of straight back). Prey captured mostly in aerial sallies, also taken from leaves, twigs and the ground by using sally-glean, hover-glean and pouncing manoeuvres. Fruits swallowed whole.
Breeding. Mid-Mar to early Aug, later, from Apr, in N of range; double-brooded. Male displays nest-site to female, female chooses site. Nest, built by female, made of mud, green moss and leaves, lined with fine grass and animal hair, placed 1-5 m up in site often protected by overhead cover, including natural rock outcropping or human structure such as bridge, building or culvert. Clutch 2-6 eggs, usually 5; incubation period c. 16 days, frequently shorter for second broods; fledging period 15-18 days. Success variable, lower in areas with higher brood parasitism by Brown-headed Cowbird (*Molothrus ater*); in E Kansas (USA) nesting success improved from 39·8%-47·1% early in breeding season to 57·1% later in season as brood parasitism decreased; in Indiana (USA) females produced on average 5·97 young per year. Capable of breeding in first season after hatching. Longevity record 9 years; adults 3-4 years old not uncommon.
Movements. Partial migrant. N populations migrate S to S USA and Mexico; present throughout year in some parts of SE & CS USA. Leaves breeding grounds late, following frost-induced insect-prey declines; departure begins Sept in extreme N, Oct over most of range, Nov in more S portions; winters in Mexico late Sept to Apr; arrival on breeding grounds early, following frost-line N, arriving in Mar over much of range, early May in N limits. Casual visitor along Pacific coast and in N Caribbean and Bermuda; vagrant in Europe (England).
Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population 16,000,000 individuals. Survey data for USA indicate no significant decline or increase since 1966, although severe winters (e.g. 1976-1977) can depress populations for several years; in Canada, populations have declined significantly in several provinces. This species' habit of using artificial structures for nesting has contributed to increased regional densities and breeding-range expansion; changing design of such structures and clearing of riparian vegetation, however, have recently had some negative impacts.
Bibliography. Anon. On following pages: 261. Say's Phoebe (*Sayornis saya*); 262. Vermilion Flycatcher (*Pyrocephalus rubinus*); 263. Austral Negrito (*Lessonia rufa*); 264. Andean Negrito (*Lessonia oreas*); 265. Spectacled Tyrant (*Hymenops perspicillatus*).

261. Say's Phoebe

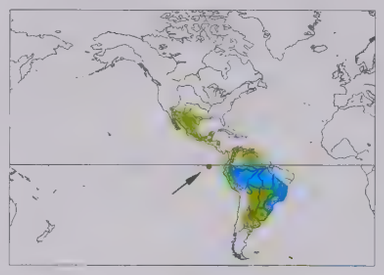
Sayornis saya

French: Moucherolle à ventre roux **Spanish**: Mosquero Llanero
German: Zimtbauch-Phoebetyrann

Taxonomy. *Muscicapa saya* Bonaparte, 1825, Arkansaw River, near Pueblo, Colorado, USA.
Taxonomy yet to be fully resolved, and analysis confounded by problems of wear and fading in museum specimens. Geographical variation in colour weak, perhaps clinal, with paler coloration in arid environments. Birds from Alaska and NW Canada described as race *yukonensis* and those of Mexican Plateau as *pallida*; both merged with nominate, although further research may indicate that one or both should be upheld. Two subspecies currently recognized.
Subspecies and Distribution.
S. s. saya (Bonaparte, 1825) - N Alaska S through W & WC USA to C Mexico; winters from S USA (California E to Texas) S to C & S Mexico.
S. s. quiescens Grinnell, 1926 - NW Mexico (N Baja California and Cedros I).

Descriptive notes. 17-19·5 cm. Slender and relatively small-headed. Nominate race is pale brown-grey above, forehead slightly paler, shading to darker grey crown and nape, lores darker; wings brown-grey, slightly paler margins on wing-coverts and remiges (remiges pale and almost translucent in flight); tail brownish-black, outer rectrix more or less edged whitish; throat and breast grey (paler than upperparts), belly, flanks and undertail-coverts cinnamon; iris dark; bill black; legs black. Sexes similar. Juvenile is slightly browner above than adult, median and greater wing-coverts tipped cinnamon-buff, forming two wingbars. Race *quiescens* is paler grey and less brown than nominate, throat whiter, narrow grey breastband, longer and wider bill. Voice. Most common vocalization "phee-eur", sometimes described as slurred "peeu" or "pu-weet". Song of rapidly repeated "pit-tsee-eur" and "pit eet" notes. Dawn song in Mexico a rapidly repeated series of "p'dew" or "pi'di-hew", with burry rolled "pi-rrep" or "prriip" and "pi-di-reep" phrases mixed in. Also gives chatter call. Bill-snapping reported during aggressive encounters.
Habitat. Breeds in open dry habitats, including prairie, sagebrush, badlands, arid and subtropical scrub, riverbanks, canyons, barren foothills, desert borders. Similar and additional more diverse habitats during migration and winter, including cultivated and riparian areas. Generally sea-level to 2500 m; in USA, breeds as high as 2850 m in Colorado and as low as 60 m below sea-level in California.
Food and Feeding. Mainly arthropods, occasionally some fruit. Diet includes bees and wasps (Hymenoptera), house flies (Muscidae), robber flies (Asilidae), craneflies (Tipulidae), grasshoppers and crickets (Orthoptera), ground beetles (Carabidae), lepidopterans, true bugs (Hemiptera), dragonflies (Odonata), spiders (Arachnida), millipedes (Diplopoda). Fruits consumed include those of elderberry (*Sambucus*), black nightshade (*Solanum*), tarweed (*Madia*) and fig (*Ficus*). Perches on ground, near ground or in low vegetation; frequently wags tail up and down. Uses aerial-sallying, hover-gleaning and pouncing manoeuvres to capture prey from the air, vegetation or ground, returning to same perch or new one.
Breeding. Mid-Apr to early Aug in much of USA and Canada and Mar-Sept in Mexico; commonly double-brooded. Hovering nest-site-showing display by male or female. Nest, built by female, a cup made of rocks, stems, wood pieces, dry grass, moss, plant fibres, dry sage bloom, wool, cocoons, spiderwebs, animal hair, infrequently also mud, often lined with animal hair or wool, average external height 7·9 cm, width 15·8 cm, length 18·6 cm, internal diameter 11·2 cm, depth 2·3 cm; placed in site protected by overhead cover on ledge of cliff face, cave, embankment, rarely in tree cavity, or artificial structure such as bridge, barn, abandoned mine, ranch building; nest often reused, enlarging base; old nest of other species, including *S. phoebe* and *S. nigricans*, Cliff Swallow (*Petrochelidon pyrrhonota*), Collared Sand Martin (*Riparia riparia*), Barn Swallow (*Hirundo rustica*) and American Robin (*Turdus migratorius*), also used. Clutch 3-7 eggs, typically 4-5; incubation period 14-17 days, in Alaska 18 days; fledging period 17-21 days. In Kansas (USA), 53% of pairs fledge more than one young per season and successful pairs fledged average of 6·13 young. Capable of breeding in first year.
Movements. Partial short-distance to long-distance migrant; present all year in much of SW USA and Mexico. Departs breeding grounds in N part of range late Aug to mid-Sept, as late as Oct in Texas; in Mexico, winters on N plateau Nov-Mar, and in Baja California. Pacific slope of Sonora and interior from C region S to Oaxaca Oct-Mar (rarely to Chiapas, Feb); arrival on breeding grounds mid-Feb to Apr in NW California, mid-Mar in Texas, Apr in Kansas, first half May in Alaska. Migration routes little known. Casual in E Canada and C & E USA. Race *quiescens* wanders to SW USA and S to Sonora.
Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population 3,700,000 individuals. Survey data from 1966 to 1996 indicate annual increase of 1·9% across range, with higher rates of increase in Canada. Has probably benefited from use of human structures as nesting sites. In SE Idaho (USA), livestock grazing had no impact on populations, but other habitat alterations due to changing agricultural practices and urbanization may adversely affect this species.
Bibliography. Anon. (1998a), Armstrong (1983), Baicich & Harrison (1997), Bent (1942), Binford (1989), Campbell *et al.* (1997), Contreras (1997), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), DeSante & George (1994), Fitzpatrick (1980a), García *et al.* (1997), González *et al.* (1997), Grinnell & Linsdale (1936), Howell & Webb (1995a), Johnsgard (1979), Kaufman (1996), Oberholser (1974), Phillips *et al.* (1964), Price *et al.* (1995), Ridgway (1907), Rosenberg *et al.* (1991), Root (1988), Ryser (1985), Sauer *et al.* (1997), Schukman (1976), Schukman & Wolf (1998), Sibley (2000), Small (1994), Stotz *et al.* (1996), Udvardy (1963), Unitt (1984), Wauer (1973).

Tribe FLUVICOLINI



Genus *PYROCEPHALUS* Gould, 1839

262. Vermilion Flycatcher

Pyrocephalus rubinus

French: Moucherolle vermillon **German**: Rubintyrann **Spanish**: Mosquero Cardenal

Taxonomy. *Muscicapa rubinus* Boddaert, 1783, Tefé, Amazonas, Brazil.
Racial boundaries poorly delineated in some cases; further research needed to clarify limits. Galapagos races (*nanus*, *dubius*) sometimes treated as one or two separate species. Birds from SE Peru (Huiro and Chaquimayo) described as race *major*, but validity has repeatedly been questioned; breeding grounds of this purported race unknown. Twelve subspecies recognized.
Subspecies and Distribution.
P. r. flammeus van Rossem, 1934 - breeds SW USA (SE California E locally to Oklahoma and Texas) S to NW Mexico; N populations winter in S of breeding range and S to Central America.
P. r. mexicanus P. L. Sclater, 1859 - S USA (S Texas) S locally to C & S Mexico.
P. r. blatteus Bangs, 1911 - SE Mexico, Belize and N Guatemala.
P. r. pinicola T. R. Howell, 1965 - E Honduras (Mosquitia) and NE Nicaragua.
P. r. nanus Gould, 1839 - Galapagos Archipelago (except San Cristóbal).
P. r. dubius Gould, 1839 - San Cristóbal I (Chatham), in Galapagos.
P. r. saturatus Berlepsch & Hartert, 1902 - NE Colombia, W & N Venezuela, Guyana and N Brazil.
P. r. piurae J. T. Zimmer, 1941 - W Colombia S to NW Peru.
P. r. ardens J. T. Zimmer, 1941- N Peru (extreme E Piura, Cajamarca, Amazonas).
P. r. obscurus Gould, 1839 - W Peru (Lima region).
P. r. cocachacrae J. T. Zimmer, 1941 - SW Peru S to extreme N Chile.
P. r. rubinus (Boddaert, 1783) - breeds SE Bolivia, Paraguay and SE Brazil S to Argentina (S to Río Negro) and Uruguay; winters mostly E of Andes N to E Ecuador and SE Colombia and E through Amazonia and S Brazil.

Descriptive notes. 13-14 cm; 11-14 g. Adult male perhaps most vibrantly coloured of family. Male nominate race has crown bright red, somewhat bushy-crested; lores, ear-coverts and nape sooty black, forming mask; upperparts sooty black; wings sooty black to blackish-brown, sometimes paler tips of median and greater wing-coverts (1-2 faint narrow wingbars); tail sooty-black, slightly darker than rump, narrow whitish tip of outer rectrix; chin, throat, head side (beneath ear-coverts) and underparts bright red; iris dark; bill black; legs black. Female differs dramatically from male: crown pale greyish-brown, dark lores contrasted by greyish-white forehead and supercilium; ear-coverts, nape and back pale greyish-brown, like crown, wings grey with pale margins on wing-coverts and remiges, rump greyish-brown, shading to blackish on uppertail-coverts, short tail blackish with whitish outer web of outer rectrix; throat white, breast white with fine grey streaks extending to flanks; lower flanks, belly and undertail-coverts sometimes tinged yellow or pink. Juvenile resembles female, but broader and whiter wing edges, pale whitish feather tips above back, whitish lower belly and undertail-coverts without yellow or pink tinge; immature male is similar to female, but with variable amounts of pink, orange or red mottling on crown and underparts. Races vary mainly in brightness of red areas and darkness of blackish parts of male, and in colour of lower underparts (ranging from whitish to yellow, pink, salmon and vermilion) and extent of streaking below of female: *mexicanus* has blackest upperparts of N races, but less dark than nominate; *flammeus* has slightly paler and greyer back than previous, red areas more orange-red, female perhaps slightly less streaked; *blatteus* is smaller than last two, red parts brighter; *pinicola* has shorter wings and tail than previous, especially female, female also more heavily streaked across breast and with underparts tinged pink (more of an orange or salmon tinge in N populations); *saturatus* similar to nominate, female is rosy pink on belly; *ardens* has crown and underparts deep orange-red, female distinctive, has pinkish tinge on forecrown, vermilion belly as bright as male's; *piurae* has very dark back, like previous; *obscurus* is very similar to nominate, back slightly less dark, up to 50% of individuals of both sexes melanistic (mainly sooty, male sometimes with variable amounts of red flecking on crown or underparts, female with pinkish lower belly), whereas (as in several other races) pale-morph females have yellow-bellied and pink-bellied forms, in addition to typical whitish-bellied form; *cocachacrae* has back slightly less dark and red areas slightly less bright than previous, both sexes also occur as melanistic morph (sooty black, male sometimes with variable amounts of red flecking on crown or underparts); *nanus* is very small, with smaller bill, has very dark back, perhaps duller rosy red underparts than mainland races, female very different from latter, has white tail tips, white throat, buffy or tawny-yellow breast and belly, faint fine grey-brown streaks on breast and flanks; *dubius* is also small, has back marginally less dark than last, female distinctive, with brown upperparts, buffish-yellow supercilium, greyish-buff throat, buffy yellow below, no streaking on breast or flanks, juvenile male like female but with short streaks on breast and buffy feather tips on back. Voice. Call a high, sharp "peent", "pisk" or "peep", by both sexes while foraging and in aggressive interactions. Song, by male at dawn, during flight display, throughout day and evening (perhaps also at night), a high tinkling "ching-tink-a-le-tink", "p-p-pik-zee" or "pit-a-zee", repeated many times; flight song also described as "titi'tr'e'e'é", "t-t-ti-ti-tee-teeur" or "pt-pt-pre-ee-see". Female gives "tjee-tjee-tjee" call to invite copulation, also during aggressive encounters with males. Other chatters similar to song but often slower. Wing-whirs may also be associated with flight display or flights between perches. Bill-snapping also recorded. Austral migrants wintering in Ecuador usually quiet.
Habitat. Variety of open, dry or moist habitats, often near water, including open woodland, clearings, arid scrub and desert scrub, *cerrado*, savanna, agricultural land; lowland pine (*Pinus*) savanna in E Honduras and NE Nicaragua (race *pinicola*). Sea-level to 3050 m.
Food and Feeding. Arthropods, including butterflies (Lepidoptera), grasshoppers and crickets (Orthoptera), beetles (Coleoptera), termites (Isoptera), bees (Hymenoptera), spiders (Araneae). Searches from low perch, from near ground to 10 m up; perches with fairly erect posture, frequently wagging tail up and down. Once located, prey pursued in aerial or perch-to-ground sallies, often returning to same perch.
Breeding. Mid-Mar to Jul in SW USA (Arizona) and Mexico; Mar-Nov in Venezuela and Oct-Jan in Argentina; fledglings in Jun in Ecuador; 1-2 broods per season. In courtship display, male, in vertical posture, crest raised, breast feathers fluffed, flutters upwards to 20-30 m up while singing, finally descending to perch. Nest a shallow open cup, appearing frail or loosely constructed, of twigs, grass, rootlets and other fibres, lichens and cocoons, bound together by spiderwebs, lined with down, feathers and hair, external diameter 6·4-7·6 cm (rarely, 9 cm), height 2·5-5·1 cm, internal diameter 4·4-5·1 cm, depth less than 2·5 cm; placed 2·4-6 m up, occasionally higher, to 18 m, in bare horizontal fork of bush or tree, sometimes near human habitation. Clutch 2-3 eggs; incubation by female, period 13-15 days; fledging period c. 13-15 days, in Argentina usually 16-18 days; both parents tend nestlings, although female spends more time at nest, whereas male spends much of time provisioning female. Of 188 nests in SW Ecuador, 93 fledged at least one young; nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*). Breeds in first season.
Movements. Mostly resident. Populations in S USA and NW Mexico (Sonora) mostly migrate S as far as Central America; leave breeding grounds late Aug/Sept-Oct, return Mar. S breeders migrate

N to as far as SE Colombia during austral winter. Altitudinal movements by some populations, moving downslope in non-breeding season. Occurs casually N & E of breeding range in USA.
Status and Conservation. Not globally threatened. Uncommon to locally common. Estimated global population 2,000,000 individuals. Population declines reported in SW USA, resulting probably from habitat destruction, cattle grazing, and water-management policies that threaten desert riparian habitats. On the other hand, often adapts to new habitats, such as golf courses and parks; local increases noted in Arizona and Mexico.

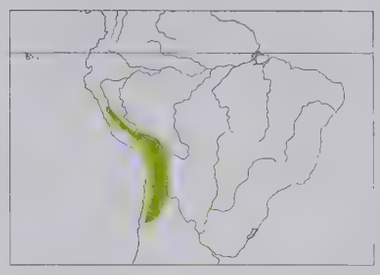
Genus *LESSONIA* Swainson, 1832

263. **Austral Negrito**

Lessonia rufa

French: Lessonie noire **German**: Patagoniensporntyrann **Spanish**: Negrito Austral
Other common names: Patagonian/(Southern) Rufous-backed Negrito

Taxonomy. [*Alauda*] *rufa* J. F. Gmelin, 1789, Buenos Aires, Argentina.
Genus considered closely related to *Knipolegus* and allies on basis of external and internal morphology. Formerly treated as conspecific with *L. oreas*. Monotypic.
Distribution. Breeds from C Chile and C Argentina S to Tierra del Fuego. Winters N Chile, S & E Bolivia, Argentina, Paraguay, SE Brazil and Uruguay.



Descriptive notes. 11·5-12·5 cm. Male is black with contrasting rufous-chestnut back; iris dark; bill short, black; legs black; hindclaw exceptionally long, like that of a pipit (*Anthus*). Differs from very similar *L. oreas* in slightly smaller size, slightly darker rufous back, dark (not whitish) inner webs of flight-feathers. Female is very different, has brownish-grey crown, dark brown nuchal collar, white eyestripe and cheek, dull rufous-brown back and scapulars; wings and tail black, outer web of outermost rectrix whitish; buffy white below, breast and sides streaked greyish-brown, flanks and belly buff, vent whitish, small cinnamon underwing patch. Juvenile resembles female, but back more rufescent; moults into immature plumage after two months, adult plumage six months later. Voice. Usually silent; alarm a repeated "tjit-tjit", contact note a short twitter.
Habitat. Open areas with short grass, usually near marshes, coasts, lagoons and beaches; also pastures. Mostly below 1000 m; locally to 2000 m.
Food and Feeding. Small insects. Basically terrestrial, usually rather active. Often perches on low bushes and fences, frequently stands on rocks and small mounds; nervously flicks tail and wings. Runs in pursuit of prey, making short sallies. May follow livestock or humans in grassy field, taking insects flushed by them. Frequently forms small, loose flocks outside breeding season.
Breeding. Breeds Sept-Nov in Chile (but Oct-Jan on Tierra del Fuego), Oct-Jan in Argentina and Dec in Bolivia; probably two broods. Displaying male flutters upwards 10-15 m. Nest a small open cup of grass, small branches or roots, lined with feathers, external diameter 6-12 cm, internal diameter 5 cm, depth 3-5 cm; frequently placed on ground or on cliff ledge, often covered by or beneath overhanging vegetation. Clutch 2-4 eggs; young attended by female only; no other information.
Movements. Migrates N after breeding, dispersing along coasts and then spreading inland across lowlands; possibly some range overlap with *L. oreas* in N Chile and Bolivia during austral winter. Males leave breeding grounds while females still caring for fledglings; on Tierra del Fuego, males depart Dec-Jan and return mid-Sept, females depart with young Feb-Mar and return early Oct. Many migrant flocks apparently made up entirely of one sex. Vagrant in Falkland Is.
Status and Conservation. Not globally threatened. Fairly common to locally abundant. Becoming increasingly common in S part of range. Occurs in all national parks along Patagonian Andes.
Bibliography. Araya & Chester (1993), Babarskas *et al.* (2003), Canevari *et al.* (1991), Chebez & Bertonatti (1994), Chesser (1997), Clark (1986), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2000, 2003), Di Giacomo (2004), Fjeldså & Krabbe (1990), Harris (1998), Hayes (1995), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Joseph (1996), Klimaitis & Moschione (1987), Lanyon (1986a), Marín (2004), Meyer de Schauensee (1966, 1982), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Nores *et al.* (1983), de la Peña (1987, 1988), Rey (2001), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Wetmore (1926), Woods (1988).

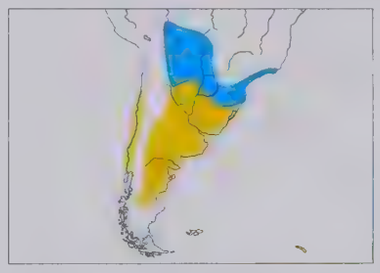
264. **Andean Negrito**

Lessonia oreas

French: Lessonie des Andes **German**: Andensporntyrann **Spanish**: Negrito Andino
Other common names: Salvin's/White-winged Negrito, (Andean) Rufous-backed Negrito

Taxonomy. *Centrites oreas* P. L. Sclater and Salvin, 1869, Tinta, Cuzco, Peru.
Genus considered closely related to *Knipolegus* and allies on basis of external and internal morphology. Formerly treated as conspecific with *L. rufa*. Monotypic.
Distribution. Andes of C & S Peru, N Chile, W & SW Bolivia and NW Argentina.
Descriptive notes. 12·5 cm. Male is black with pale rufous back; inner webs of flight-feathers silvery white (usually visible only in flight); iris dark; bill short, black; legs black; hindclaw exceptionally long, like that of a pipit (*Anthus*). Differs from very similar *L. rufa* in slightly smaller size, slightly paler rufous back, whitish inner webs of remiges. Female is smaller than male, blackish-brown above, back dull rufous, chin whitish, sooty below, breast side dull rufous, crissum blackish; much darker below than female *L. rufa*. Juvenile is like female, but much paler overall. Voice. Contact call a short, rather faint "tyt", repeated at c. 0·5-second intervals; alarm a very high-pitched "zi".

Habitat. Montane lakes, streams and bogs with short vegetation and muddy areas, heavily grazed lakeshores, also seasonally flooded plains. Mostly 3000-4000 m; occasionally above 4000 m (Peru) or below 1000 m (Chile). Replaces *L. rufa* in Altiplano.
Food and Feeding. Small insects. Usually occurs in pairs or family groups. Basically terrestrial. Frequently perches on tussocks or other slightly elevated perches. Makes short sallies and flights to catch insects close to or on ground; also pursues prey by running on ground in short quick bursts.
Breeding. Oct-Jan in N Chile. Displaying male flutters upwards 10-15 m. Nest usually an open cup similar to that of *L. rufa*, concealed in tussock or grass. Clutch 3-4 eggs; no other information.
Movements. Resident. May overlap with *L. rufa* in N Chile and Bolivia, during austral winter.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Becomes more numerous towards N of range. Occurs in Lauca National Park, in Chile, and common around Junín National Reserve, in Peru.
Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chapman (1921), Chesser (1997), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Jaramillo (2003), Johnson (1967), Kent *et al.* (1999), Koepcke (1970), Lanyon (1986a), Marín (2004), Meyer de Schauensee (1966, 1982), Narosky & Salvador (1998), Ridgely & Tudor (1994), Rocha & Peñaranda (1995), Rocha & Quiroga (1996, 1998), Ridgely & Greenfield (2001), Sick (1993), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Zimmer (1930).



Genus *HYMENOPS* Lesson, 1828

265. **Spectacled Tyrant**

Hymenops perspicillatus

French: Ada clignot **German**: Brillendunkeltyrann **Spanish**: Viudita Picoplata

Taxonomy. *Motacilla perspicillata* J. F. Gmelin, 1789, Montevideo, Uruguay.
Name formerly used for genus was *Lichenops*, but present name has priority. Appears closely allied to *Knipolegus*. Two subspecies recognized.
Subspecies and Distribution.
H. p. perspicillatus (J. F. Gmelin, 1789) - extreme SE Brazil, Paraguay and Uruguay S in lowlands to CS Argentina (Río Negro); winters in Paraguay, C Bolivia and S Brazil.
H. p. andinus (Ridgway, 1879) - breeds C Chile (Atacama S to Aisén) and S Argentina (W Río Negro, Chubut, N Santa Cruz); winters in N Argentina.

Descriptive notes. 13-16 cm. Distinctive, with prominent greenish-tinged yellow fleshy wattle around eye. Male is black overall; primaries mostly white with black base and tips (visible at rest, conspicuous in flight); iris yellow; bill pale yellow, appearing almost white at distance; legs black. Female is dark brown above, buffy or buff-white supercilium and pale lores, wattle reduced and duller; back streaked black with pale brown edges; two buffy wingbars, distinctive rufous remiges (visible in flight); tail dark; pale dusky or whitish below, dusky streaking across chest; bare parts as male, but bill dusky with brown lower mandible. Both sexes have wattle reduced in non-breeding season. Juvenile is similar to female. Race *andinus* is slightly larger than nominate, white area of outer five primaries somewhat reduced, wing slightly shorter, female has breast less boldly streaked. Voice. Usually silent. Male utters a series of thin, squeaky notes; during display, male utters "zheeeee", also "buzz" produced by primaries.
Habitat. Marshes, grassy or shrubby areas, rivers, open lands, and fields and pastures near water; sea-level to c. 2000 m, locally to 3350 m.
Food and Feeding. Insects. Usually solitary. Prey pursued and captured on the ground, or during sallies from posts, bushes or reeds.
Breeding. Oct-Jan in Argentina and Nov-Jan in Chile. During spectacular display, male rises up to 10 m above perch, making loud bill-snap at peak, then drops straight down, wings half-closed, uttering loud cry; primaries produce buzzy whistle throughout flight; male often perches on fence posts or other exposed lookouts. Nest an open but small, deep cup, hidden in or at base of shrub near ground, usually in clump of grass or reeds, sometimes attached to reeds; for three nests in Argentina, external diameter 4·4-10 cm, internal diameter 3·5-6·5 cm, depth 3·7-6 cm. Clutch 2-4 eggs; no information on incubation and fledging periods. Nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Partial migrant; some populations in S Paraguay apparently resident. After breeding, nominate race migrates N to Paraguay, C Bolivia and S Brazil; *andinus* migrates E across Andes from Chile to lowland Argentina. Accidental in Peru, e.g. Tambopata-Candamo Reserved Zone (Cuzco).
Status and Conservation. Not globally threatened. Fairly common to common. Abundant near coastal marshes in S Buenos Aires (Argentina) in Apr. Fairly common in Los Glaciares National Park, in Argentina; occurs also in several other national parks and protected areas, especially in non-breeding season.
Bibliography. Genus *KNIPOLEGUS* Boie, 1826

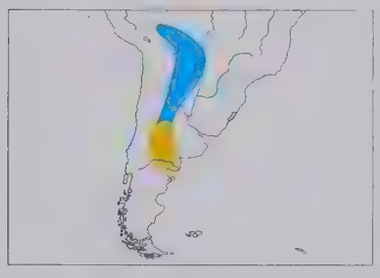
266. Cinereous Tyrant

Knipolegus striaticeps

French: Ada cendré **German**: Schwarzmasken-Dunkeltyrann **Spanish**: Viudita Chaqueña

Taxonomy. *M[uscisaxicola] striaticeps* d'Orbigny and Lafresnaye, 1837, "La Paz" = Chiquitos, Bolivia.
Formerly placed in a monotypic genus, *Entotriccus*, on basis of uniformly narrow primaries of both sexes. Monotypic.
Distribution. E & S Bolivia (Santa Cruz, Tarija), S Brazil (Mato Grosso), W Paraguay (W of R Paraguay) and NW Argentina (Jujuy and Formosa S to Córdoba and La Rioja).



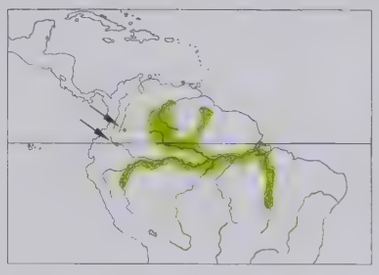
Descriptive notes. 13-13·5 cm. Male is mostly dark grey, darker head imparting distinctly hooded effect; face blackish-grey; wings dusky grey or blackish-grey, two narrow pale grey wingbars, inner remiges edged greyish; tail dusky, outer web of outer rectrices pale; throat and chest duskier; lower underparts greyish-white or whitish with fine dusky streaks; iris bright scarlet-red; bill black; legs black. Differs from congeners in smaller size, no concealed white in wings. Female is olive-brown above, rufous on crown, lores whitish, nape with dusky streaking; wingbars white, uppertail-coverts rufous, tail with rufous inner webs, iris pale brown; smaller and with less deep rufous tail-coverts than female *K. hudsoni*. Voice. Quiet; displaying male gives "ts-ip" call while perched, and staccato "skidi-ik" (possibly wing noise) at bottom of display-flight.
Habitat. Chaco woodland, borders and openings; also dense groves of forest in *campo* regions in Brazil. Mostly below 1000 m, locally to 1900 m.
Food and Feeding. Insects. Usually found singly, occasionally in pairs. Perches on exposed bushes or low trees, erect and alert, frequently twitching tail; sallies for prey.
Breeding. Recorded in Nov-Feb in Argentina. Displaying male flies up from exposed perch to 8-15 m, folds wings and drops to new perch. In Argentina, nest an open cup made from grass, horsehair and feathers, placed in cactus; clutch 2 eggs. No other information.
Movements. Not well known. Reportedly migratory in S part of range, but details unknown; single specimen in Paraguay E of R Paraguay suggests some movement.
Status and Conservation. Not globally threatened. Fairly common to locally common. Chaco woodland is increasingly being cleared for cattle grazing and agriculture, putting this species at some risk.
Bibliography. Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Hayes (1995), Lanyon (1986a), López (1997), Meyer de Schauensee (1966, 1982), Miserendino (1998), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), Olrog (1979b), de la Peña (1988), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Wetmore (1926).

267. Hudson's Black-tyrant

Knipolegus hudsoni

French: Ada de Hudson **German**: Weißflanken-Dunkeltyrann **Spanish**: Viudita Patagona

Taxonomy. *Cnipolegus hudsoni* P. L. Sclater, 1872, Río Negro, Patagonia.
Formerly placed with *K. poecilocercus* in defunct genus *Phaeotriccus* on basis of shape of outer primaries. Monotypic.
Distribution. Breeds C Argentina from Córdoba S to Neuquén, Río Negro and SW Buenos Aires; migrates N to Bolivia and S Brazil.



Descriptive notes. 15·5 cm. Male plumage is shiny black, underwing with large white patch across inner webs of primaries (conspicuous in flight, not visible when perched); some whitish on lower flanks; outer three primaries strongly narrowed; iris red; bill blue-grey, tipped black; legs black. Distinguished from very similar *K. aterrimus* by much smaller size; from similar *K. poecilocercus* by larger size, white on underwing. Female is greyish-brown above, becoming rufous on rump and basal half of tail, terminal tailband blackish, wings dusky with two buff wingbars, outer primaries as male, buffy below with mottled dusky-olive streaking across breast, fewer streaks on belly; similar to female *K. atterimus* but smaller, with heavy streaking below. Voice. Irregular "ric-tic-titireetic" and snapping sounds.
Habitat. Low woodland and scrub; also Chaco and overgrown pastures and gardens in non-breeding season. Mostly below 500 m.
Food and Feeding. Little known. Insects eaten. Usually inconspicuous, preferring dense cover close to ground.
Breeding. Male displays from emergent, usually dead tree, jumping restlessly from branch to branch, occasionally flying up and vocalizing. Nest an open cup, usually placed in small tree or bush. No other information.
Movements. Migrates N in Aug-Sept to Paraguay, Bolivia and S Brazil; recorded as far N in Mato Grosso as Serra do Roncador.
Status and Conservation. Not globally threatened. Generally rare to locally uncommon. Fairly common to common during breeding season in Lihué Calel National Park (La Pampa); has been recorded during migration in Beni Biosphere Reserve, in Bolivia. N limit of breeding uncertain; possibly extends farther N than currently known.
Bibliography. Brace *et al.* (1996, 1997), Canevari *et al.* (1991), Chebez (1994), Chesser (1997), Collar *et al.* (1994), Cory & Hellmayr (1927), Davis (1993), Fjeldså & Maijer (1996), Joseph (1996), Lanyon (1986a), Meyer de Schauensee (1966, 1982), Narosky & Di Giacomo (1993), Narosky & Yzurieta (1993), Nores *et al.* (1983), Hayes (1995), de la Peña (1988), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Veiga *et al.* (2002), Wetmore (1926).

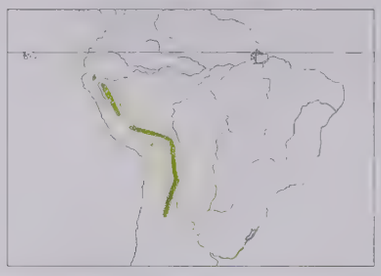
268. Amazonian Black-tyrant

Knipolegus poecilocercus

French: Ada d'Amazonie **German**: Várzeadunkeltyrann **Spanish**: Viudita Amazónica

Taxonomy. *Empidochanes poecilocercus* Pelzeln, 1868, River Amajaú, Rio Negro, Brazil.
Formerly placed with *K. hudsoni* in defunct genus *Phaeotriccus* on basis of shape of outer primaries. Monotypic.
Distribution. S Venezuela (W Apure, Amazonas), N Brazil (R Negro S to N bank of Amazon and to R Nhamundá, also E on S bank to R Tocantins) and NE Peru (Sarayacu, R Ucayali); also locally in Guyana, E Colombia (W Meta) and NE Ecuador.

Descriptive notes. 12·7-13·5 cm; 14 g. Large eyes, long rictal bristles. Male is glossy black with slight bluish sheen; primaries tinged brownish, outer three short, narrow and pointed (visible in hand); iris dark; bill stout, bluish or bluish-grey, tipped black; legs black. Distinguished from similar *K. orenocensis* by considerably smaller size, glossier plumage. Female is olive-brown above, lores and eyering greyish-white, uppertail-coverts rufous, wings dusky with two cinnamon-buff wingbars and buff edgings, outer primaries as male, short tail dusky, edged cinnamon, pale buff below, lower throat, breast and flanks streaked brownish-olive (forming chestband), underwing-coverts white, large eyes dark brown, bill dusky brown; differs from similar *Myiophobus fasciatus* in more olive plumage, rufous tail-coverts, stronger streaking below. Voice. Unusually quiet. Displaying male has faint clicking "tic-dik" or vaguely trebled "see-sa'lick" or more buzzy "bzzéa", also high "tsik" while opening wings slightly; female a louder "pit-pit".
Habitat. *Várzea* forests, prefers dark vine tangles near open water; also damp thickets and seasonally flooded areas. To 350 m.
Food and Feeding. Insects. Usually solitary or in pairs, inconspicuous unless displaying; female sometimes associated loosely with mixed-species flocks. Often perches at or below eye level. Sallies to foliage, occasionally to surface of shallow water or to the ground; movements often sudden and reminiscent of those of a manakin (Pipridae).
Breeding. Nest-building in Feb in Venezuela (Hato Cedral) and Jul in Brazil. Displaying male, usually from thick vine, jumps vertically, calls, and returns to original perch, sometimes makes soft snapping sound; in presumed aggressive display follows other males, holding head and tail lowered and wings fanned. Nest (Brazil) an untidy ball of moss and grass, 1 m up in branch fork at edge of small forest stream. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare or uncommon to locally common; probably often overlooked. Occurs in Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, and Anavilhanas Ecological Station and Jaú and Tapajós National Parks, in Brazil.
Bibliography. Cory & Hellmayr (1927), Cracraft (1985), Hilty (1999, 2003), Hilty & Brown (1986), Lanyon (1986a), Meyer de Schauensee (1966, 1982), Oren & Parker (1997), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Traylor (1977), Zimmer (1937a, 1937b).



269. Andean Tyrant

Knipolegus signatus

French: Ada de Jelski **German**: Andendunkeltyrann **Spanish**: Viudita Andina
Other common names: Jelski's Bush-tyrant (*signatus*); Plumbeous (Andean) Tyrant (*cabanisi*)

Taxonomy. *Ochthodiaeta signatus* Taczanowski, 1875, Auquimarca and Ninabamba, Peru.
Taxonomic history complex. Races earlier treated as two distinct species in separate genera, nominate being placed in *Ochthodiaeta* (now *Myiotheretes*) and *cabanisi* in present genus; subsequent authors generally considered them conspecific, and moved nominate to current genus, although with suggestion by some that they may be separate species. More recently, various authors have treated races either as conspecific or as representing two distinct species forming a superspecies. Two subspecies recognized.
Subspecies and Distribution.
K. s. signatus (Taczanowski, 1875) - extreme S Ecuador, N & C Peru (Amazonas to Huánuco, Junín).
K. s. cabanisi Schulz, 1882 - SE Peru (E Cuzco, N Puno), SE Bolivia (Cochabamba, Santa Cruz, Tarija) and NW Argentina (Jujuy S to Catamarca and Tucumán).
Descriptive notes. 14·5-16·5 cm. Male nominate race has plumage uniform sooty black; iris dark red or chestnut; bill blackish; legs black. Differs from *K. aterrimus* in less shiny black plumage, no white in wing. Female is dark dull olive-brown above, more rufous on uppertail-coverts, two whitish to buff wingbars, dusky tail narrowly edged cinnamon-rufous, broadly streaked dark greyish-olive below, especially on breast (often uniform-looking), dark buffy crissum. Juvenile is like female, upperparts washed rusty, wingbars white, pale yellow panel on wing, pale streaks below more extensive, tinged pale yellow. Race *cabanisi* is smaller than nominate, overall more dark slate-grey, wings and tail dusky, inner webs of remiges edged white, paler below, especially lower belly, bill blue-grey with black tip and paler lower mandible; female dull brown above, becoming bright rufous on tail-coverts and edges of tail feathers, two buffy-white wingbars and ochraceous

On following pages: 270. Blue-billed Black-tyrant (*Knipolegus cyanirostris*); 271. Rufous-tailed Tyrant (*Knipolegus poecilurus*); 272. Riverside Tyrant (*Knipolegus orenocensis*); 273. White-winged Black-tyrant (*Knipolegus aterrimus*); 274. Crested Black-tyrant (*Knipolegus lophotes*); 275. Velvety Black-tyrant (*Knipolegus nigerrimus*).

wing panel, buffy white below, broadly streaked greyish-olive, especially on breast (sometimes uniform), bill blackish. Voice. Male (race *cabanisi*) utters "tec" call, also makes wing-whirring noise, during display.

Habitat. Interior of lower growth of humid montane forest and woodland, less often at borders; also along paths, edges, clearings in patchy woods, and in alder (*Alnus*) thickets and second growth on slopes along streams. At 1900-3050 m in N of range (nominate); 700-2500 m in S (*cabanisi*).

Food and Feeding. Little known. Insects. Usually inconspicuous and quiet; also generally solitary, and does not follow mixed-species flocks. Perches upright, with head tucked between shoulders, breast feathers puffed, and tail constantly vibrating or shivering from side to side.

Breeding. Eggs in Oct-Jan in Argentina. Displaying male flies straight up for 2-10 m with wing-whirring, glides at top and makes "tec" sound, then drops, wings closed, back to perch. Nest an open cup made of grasses and moss, lined with feathers, external diameter c. 14 cm, height 7·5-12 cm, internal diameter 4-6 cm, depth 3-4 cm, usually up to 4 m above ground on horizontal branch in small tree or bush. Clutch 1-3 eggs. Nest parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Rare and very poorly known in Peru; fairly common in Argentina. Occurs in Machu Picchu Historical Sanctuary, in Peru, Pilón Lajas Biosphere Reserve and Iñao, Tarija and Madidi National Parks, in Bolivia, and Baritú and Calilegua National Parks, in Argentina. Readily found in alder woodland in the Yala Valley above city of Jujuy, in N Argentina.

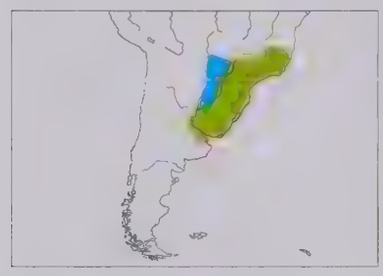
270. **Blue-billed Black-tyrant**



Knipolegus cyanirostris

French: Ada à bec bleu **German**: Einfarbdunkeltyrann **Spanish**: Viudita Picoceleste

Taxonomy. *Muscicapa cyanirostris* Vieillot, 1818, Paraguay.

Monotypic.

Distribution. SE Brazil (N to Minas Gerais and Espírito Santo), Uruguay and NE Argentina (Misiones S to Buenos Aires); S populations winter N to SC Brazil (S Mato Grosso) and E Paraguay.

Descriptive notes. 14·5-15 cm. Male plumage is all glossy black, except for faint white edges on underwing (remiges); iris bright red; bill pale blue bill with black tip; legs black. Female is rufous-brown above, crown brighter rufous, rump rufous, tail-coverts bright cinnamon, blackish wings with two buff to cinnamon wingbars, dusky tail edged rufous, whitish to yellowish-white below, heavily streaked blackish-brown and dirty white, crissum cinnamon-rufous, iris pale red to orange, bill blackish, usually with bluish lower mandible; distinguished from *K. striaticeps* by larger size and darker overall coloration, from similar *Myiophobus fasciatus* by much larger size, more prominent streaking below. Voice. Generally quiet; barely audible "it" call while perched.

Habitat. Borders of humid forest and gallery woodland, less often venturing out into shrubby semi-open areas, usually near water; usually not found in interior of forest. Below 2200 m.

Food and Feeding. Insects. Usually in pairs, often inconspicuous. Generally perches at low levels; occasionally takes high exposed perch for protracted periods. Hunts in short, rapid sallies or gleans from foliage, often remaining low.

Breeding. Little known. Nov-Dec in Argentina. Male, with wings raised, glides silently down in front of female. Nest an open cup made of small sticks and grass, lined with soft material and feathers, placed on tree branch, sometimes at outer end; one nest with external diameter 11·5 cm, height 6 cm, internal diameter 5 cm, depth 4 cm. Clutch 1-3 eggs. Nest parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded. No other information.

Movements. Austral migrant; those breeding in S of range mainly migrate N as far as Paraguay and SC Brazil (Mato Grosso) during austral winter.

Status and Conservation. Not globally threatened. Uncommon to locally common or abundant. Appears to be most numerous in SE Brazil, e.g. Rio Grande do Sul. Recorded in Mata dos Godoy State Park (Paraná), Patrimônio Natural do Caraça Special Reserve and Aparados da Serra, Caparaó and Itatiaia National Parks, all in Brazil, and San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), in Argentina.

Bibliography. Babarskas *et al.* (2003), Belton (1985), Blake, E.R. (1953), Canevari *et al.* (1991), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Guix (1995), Hayes (1995), Joseph (1996), Klimaitis & Moschione (1987), López (1997), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Wetmore (1926), Willis (1988).

271. **Rufous-tailed Tyrant**

Knipolegus poecilurus

French: Ada à queue rousse **German**: Fahlbauch-Dunkeltyrann **Spanish**: Viudita Colirrufa

Taxonomy. *Empidochanes poecilurus* P. L. Sclater, 1862, "Bogotá", Colombia.

Formerly placed in genus *Cnemotriccus*, and later in a newly erected monotypic genus, *Eumyiobius*; appears, however, to be closely related to members of present genus, despite lack of marked sexual plumage dimorphism. Races generally poorly differentiated, and individual variation often greater than variation among taxa; further evaluation needed. Five subspecies currently recognized.

Subspecies and Distribution.

K. p. poecilurus (P. L. Sclater, 1862) - mountains of Colombia (except Santa Marta) and extreme NW Venezuela (Sierra de Perijá).

K. p. venezuelanus (Hellmayr, 1927) - W & N Venezuela (Táchira, Mérida, Distrito Federal).

K. p. paraquensis Phelps, Sr & Phelps, Jr, 1949 - Cerro Sipapo (Paraque), in NW Amazonas (Venezuela).

K. p. salvini (P. L. Sclater, 1888) - S Venezuela (cerros of C & S Amazonas and S Bolívar) and immediately adjoining N Brazil and W Guyana.

K. p. peruanus (Berlepsch & Stolzmann, 1896) - Andes from E Ecuador S to SE Peru (Cuzco) and C Bolivia.

Descriptive notes. 14·5-15 cm; 13-15 g. Male nominate race is greyish to brownish-grey above; wings dusky, two broad buffy-grey wingbars (often absent), buff edges of inner remiges; tail dusky, inner webs broadly edged cinnamon (conspicuous in flight); throat whitish, underparts mostly dull buffy grey or cinnamon-buff, washed with grey across breast; underwing-coverts cinnamon; iris red (not conspicuous); bill fairly long, black; legs black. Female is slightly browner than male. Juvenile is washed with rufous, has iris brown, more extensive rufous in tail webs, cinnamon wingbars often present. Race *peruanus* is similar to nominate, on average darker, highly variable (depending on age, also degree of wear); *salvini* is grey above, contrasting white belly and rufous vent, no wingbars, adult male with very little rufous in tail; *venezuelanus* is intermediate between previous and more cinnamon-tinged nominate; *paraquensis* is smaller and darker overall, with plain wings and no rufous in tail. Voice. Usually quiet; call a short, metallic trill, "tzteeer" or "triiit".

Habitat. Borders of humid and wet montane or second-growth forest, pastures with scattered trees, and grassy slopes with some scrub; also dense, stunted second growth dominated by melastomes (Melastomataceae) on white sandy soils. At 650-3100 m; 900-2400 m in N (Venezuela).

Food and Feeding. Insects. Usually singly or in pairs, seldom with mixed-species flocks. Perches upright, sometimes in the open, but sometimes shy; often lifts tail and then slowly lowers it, or cocks tail; recalls *Sayornis*. Makes short sallies for flying prey from low bushes, or drops to the ground.

Breeding. Birds with enlarged gonads in Mar-Sept in Colombia. No other information.

Movements. Resident; probably wanders more often than reported, frequently appearing at fresh landslides where previously not present. Worn specimen from Bolivia identified as of race *venezuelanus*, although in range of quite different *peruanus*.

Status and Conservation. Not globally threatened. Generally rare to uncommon, locally more common. Common at La Planada Nature Reserve (Nariño), in Colombia; uncommon around treefalls and in stunted ridgecrest forest (from 1300 m upwards) on Mt Roraima, in Guyana. Also occurs in Podocarpus National Park, in Ecuador, and Machu Picchu Historical Sanctuary, in Peru.

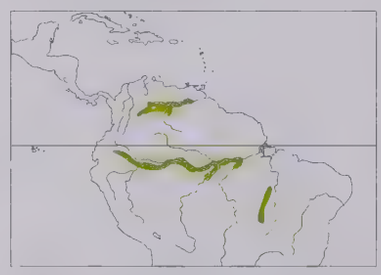
Bibliography. Barrowclough *et al.* (1997), Chapman (1917c, 1921, 1931), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Mayr & Phelps (1967), Meyer de Schauensee (1982), Miller (1963), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Strewe (2000a), Walker (2001), Willard *et al.* (1991).

272. **Riverside Tyrant**

Knipolegus orenocensis

French: Ada de l'Orénoque **German**: Flussufer-Dunkeltyrann **Spanish**: Viudita Ribereña

Taxonomy. *Cnipolegus orenocensis* Berlepsch, 1884, Angostura [= Ciudad Bolívar], River Orinoco, Venezuela.



Race *sclateri* possibly a separate species, exhibits marked sexual plumage dimorphism whereas nominate and *xinguensis* do not; insufficient information currently available to enable full assessment of taxonomy. Three subspecies recognized.

Subspecies and Distribution.

K. o. orenocensis Berlepsch, 1884 - E Colombia (NE Meta) and C Venezuela (lower R Apure and upper R Orinoco E to Ciudad Bolívar).

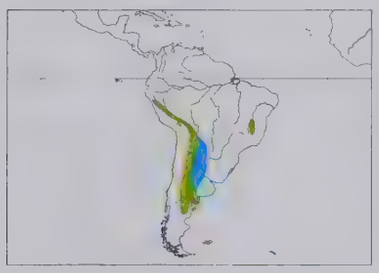
K. o. sclateri Hellmayr, 1906 - NE Ecuador (R Napo) through NE Peru (E Loreto) to NC Brazil (R Madeira E to R Tapajós).

K. o. xinguensis Berlepsch, 1912 - E Brazil (lower R Xingu and R Araguaya).

Descriptive notes. 15-15·5 cm; 19 g. Male nominate race is uniform slate-grey or blackish-grey, head blackest with slight crest, giving slight "puff-headed" appearance; iris dark; bill thickish, pale blue-grey, black tip; legs black. Female is slightly paler than male, slate-grey with olive tinge. Juvenile resembles female, underparts with blurry buff streaking. Race *xinguensis* is very like nominate, but slightly larger, female somewhat paler; *sclateri* male is uniformly dull black, female very different, dull olive-grey above, rump washed rufescent, pale below, coarse olive-greyish streaks on throat, chest (especially) and flanks, juvenile brownish-grey with rufous rump, rufous edging and tips on wing-coverts (faint wingbars), rufous edges of rectrices, buff-tinged underparts with diffuse streaking. Voice. Soft, musical "peéeo" with downward inflection; "tuk" contact note during foraging; call a soft stuttering "pi-weet" or "pi-piweet". Displaying male produces mechanical snaps.

Habitat. Semi-open scrub along rivers and near lakes; most often in early-successional growth (especially among *Tessaria* and *Cecropia* saplings) on seasonally flooded river islands. Occurs below 300 m.

Food and Feeding. Insects. Usually singly or in pairs. Sometimes perches conspicuously on bushes or low trees (though usually in partial cover), especially in morning; at other times, however, wary and difficult to approach. Frequently drops to the ground in pursuit of prey; less often sallies to grass or aerially.



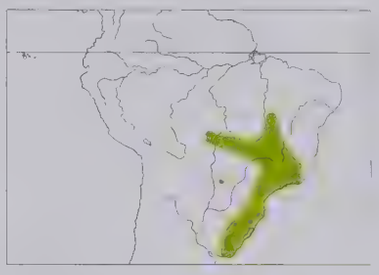
Breeding. Mar in E Colombia (NE Meta); juvenile in Apr in Venezuela; family party seen in Sept in Ecuador. Male has display typical of genus, repeatedly flies straight up and then drops. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon and local; restricted to Orinoco and Amazon rivers and some of their tributaries. Regularly found on river islands near Puerto Ayacucho, in Venezuela; few records from Ecuador, along R Napo near La Selva Lodge.
Bibliography. Cherrie (1916), Cory & Hellmayr (1927), Friedmann (1948), Hilty (1999, 2003), Hilty & Brown (1986), Forrester (1993), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer (1937a).

273. White-winged Black-tyrant

Knipolegus aterrimus

French: Ada à ailes blanches **German**: Weißspiegel-Dunkeltyrann **Spanish**: Viudita Aliblanca
Other common names: Caatinga Black-tyrant (*franciscanus*)

Taxonomy. *Cnipolegus aterrimus*, Kaup, 1853, Cochabamba, Bolivia.
Geographically isolated race *franscianus* has been considered to be a separate species, but field data and museum specimens generally lacking; current treatment maintained pending further information. Four subspecies recognized.
Subspecies and Distribution.
K. a. heterogyna Berlepsch, 1907 - N Peru (Marañón Valley from Cajamarca S to Ancash).
K. a. anthracinus Heine, 1859 - S Peru (Ayacucho, Cuzco, N Puno) and NW Bolivia (La Paz).
K. a. aterrimus Kaup, 1853 - S Bolivia (Cochabamba and Santa Cruz S to Potosí and Tarija) and W Argentina (S to Chubut); also Paraguay and NE Argentina in non-breeding season.
K. a. franciscanus E. Snethlage, 1928 - E Brazil (São Francisco Valley in SW Bahia and N Minas Gerais, also Distrito Federal).



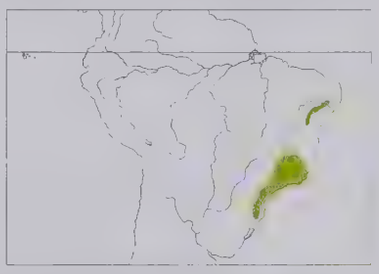
Descriptive notes. 16-18 cm. Male nominate race is shiny black overall, with large white band across inner webs of primaries (usually hidden at rest, conspicuous in flight); iris dark brown; bill blue-grey, black tip; legs black. Female is greyish-brown above, crown slightly darker, face and lores freckled or mottled whitish, two whitish-buff or cinnamon-buff wingbars, remiges edged rufous or whitish, rump and basal half of tail bright cinnamon-rufous, rest of tail dark brown with darker terminal band; buffy ochraceous below, strongest on chest, whiter on throat and mid-belly, bill black, lower mandible with bluish base. Races differ mainly in plumage of female: *anthracinus* male is duller black than nominate, female is smaller, with mottled dusky streaks on breast, less rufous on tail; *heterogyna* male is like previous, female is darker above and paler below, pale buff at base of tail; *franciscanus* smaller, female is whitish below, chest washed buffish and heavily streaked. Voice. A female-plumaged bird uttered "trrie rrhi rrhi, trrie rrhie rrhie, trrhie rrhit" while foraging near ground; also, a thin, wiry "chit-tzzzr"; migrants give faint "tseet". During male display, weak series of mechanical buzzing and clicking sounds, along with "toc-tek".
Habitat. Light scrub, woodland, and forest borders, mostly in arid regions. Race *anthracinus* in second growth on forest clearings and landslides, humid open shrubby forest; nominate race in dense thickets of thorny trees, riparian willow (*Salix*) thickets in arid zone. During migration occurs also in open brush on gravelly hillsides. Mostly 1500-3000 m, occasionally down to 250 m or as high as 3700 m.
Food and Feeding. Insects. Generally solitary, though usually not shy. Usually perches with erect posture in the open, occasionally inside canopy; flicks tail. Sallies from exposed branches or rocky outcrops, gleans from foliage, or drops to the ground.
Breeding. Oct-Feb; eggs in Oct-Nov and fledgling in Nov in Bolivia; display observed in Dec-Feb. Male displays with short flight upwards from perch, followed by stalling and plummeting backwards, then pulls out of dive back to perch, sometimes with faint vocalization; display can include clicking and buzzing at peak. Nest an open cup made of twigs, lined with feathers and hair, placed low in tree or bush, occasionally on ground; in Argentina, one nest elipse, 11 × 13 cm, height 4·5 cm, internal diameter 6·5 cm, depth 2·5 cm, another with external diameter 12 cm, internal diameter 6 cm, depth 3·5 cm. Clutch 2-3 eggs; no information on incubation and fledging periods. Male may apparently breed while still in immature plumage.
Movements. S race (nominate) moves N in Mar-Apr, returns in Nov; recorded during austral winter in Paraguay, e.g. in Teniente Enciso National Park and Chaco of Fortín General Díaz; recent record also from SC Brazil (W Mato Grosso do Sul). Possibly also performs some elevational movements.
Status and Conservation. Not globally threatened. Race *franciscanus* (sometimes treated as separate species) a Restricted-range taxon: present in Deciduous Forests of Minas Gerais and Goiás EBA. Fairly common to common; abundant in NW Argentina. Found typically in inhabited areas in montane basins, and occurs also in Madidi National Park, in Bolivia; in Machu Picchu Historical Sanctuary, in Peru, can be found all along the road from train station to the ruins.
Bibliography. Bornschein *et al.* (2003), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Cracraft (1985), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Friedmann (1927), Hayes (1995), Kirwan *et al.* (2004), Joseph (1996), de Lima (1999), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1988), Perry *et al.* (1997), Quiroga *et al.* (1998), Ridgely & Tudor (1994), Rocha & Quiroga (1996), Schulenberg *et al.* (2001), Short (1975), Sick (1993, 1997), da Silva & Oren (1992), Stotz *et al.* (1996), Straneck & Carrizo (1983), Walker (2001), Wetmore (1926), Willis & Oniki (1991).

274. Crested Black-tyrant

Knipolegus lophotes

French: Ada huppé **German**: Haubendunkeltyrann **Spanish**: Viudita Copetona

Taxonomy. *Knipolegus lophotes* Boie, 1828, São Paulo, Brazil.
Monotypic.
Distribution. S Brazil (S Mato Grosso E to W Bahia and Espírito Santo, S to Rio Grande do Sul), NE Paraguay (Cerro Amambay) and Uruguay.



Descriptive notes. 20-21 cm. Large and conspicuously black-crested. Plumage is glossy blue-black, head with long, slender, pointed crest; base of remiges white (hidden or mostly so at rest, conspicuous in flight); iris dark red or reddish-brown; bill black; legs black. Sexes similar, female slightly smaller than male. Voice. Usually silent; night song reported to be modulated, ascending and descending notes with short trill, "dewéé-kwirr".
Habitat. Savannas, open grassy or shrubby areas, often near groves of trees; mostly below 1100 m.
Food and Feeding. Insects, occasionally small fruit; at one site in Minas Gerais, berries of *Miconia albicans* (Melastomataceae) were apparently an important component. Generally conspicuous, though usually in highly dispersed pairs. Sallies for prey.
Breeding. Little information. Apparently breeds Sept-Nov in Brazil. Two neighbouring territories in Minas Gerais were of 6·5 ha and 7·7 ha. Nest on small ledge, c. 3·5 m above ground level, in a damp, shaded, concealed site; open, circular nest made of twigs, roots and lichens.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Poorly known. Appears to have large home ranges. In Brazil, locally common below Itatiaia National Park, and occurs also in Caparaó and Serra da Canastra National Parks and Patrimônio Natural do Caraça Special Reserve.
Bibliography. Arballo (1990), Bauer & Pacheco (2000), Blake, E.R. (1953), Claramunt (1999), Cory & Hellmayr (1927), Cracraft (1985), Develey (2004), Dubs (1992), Forrester (1993), Hayes (1995), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Ribeiro *et al.* (2002), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Venturini *et al.* (2001), Willis & Oniki (1990).

275. Velvety Black-tyrant

Knipolegus nigerrimus

French: Ada noir **German**: Kurzschopf-Dunkeltyrann **Spanish**: Viudita Aterciopelada

Taxonomy. *Muscicapa nigerrima* Vieillot, 1818, Brazil.
Two subspecies recognized.
Subspecies and Distribution.
K. n. hoflingi Lencioni, 1996 - NE Brazil, from W Pernambuco to C Bahia (Chapada Diamantina).
K. n. nigerrimus (Vieillot, 1818) - CE & SE Brazil, from Minas Gerais and Espírito Santo to Paraná and Rio Grande do Sul, including hills of Rio de Janeiro (Corcovado, Pico da Tijuca, Pico da Gavea).

Descriptive notes. 17·5-18 cm. Male plumage is glossy blue-black, head with small bushy crest; base of primaries white (hidden or mostly so at rest, conspicuous in flight); iris dark red; bill pale bluish-grey; legs black. Female is similar to male but lacks crest, and has throat chestnut, streaked black. Race *hoflingi* is somewhat smaller, with brown (not black) primaries, female with narrower throat patch. Voice. Unknown.
Habitat. Grassy or rocky areas, usually near trees or shrubby cover; mostly 1800-2700 m, locally down to 700 m.
Food and Feeding. Insects. Generally in pairs, and often conspicuous. Usually forages near ground, sallying for prey.
Breeding. No information. Believed to nest in burrows among rocks near streams.
Movements. Reportedly an altitudinal migrant during austral winter in Itatiaia; probably resident elsewhere.
Status and Conservation. Not globally threatened. Uncommon to fairly common, locally common. Common near the Corcovado Statue above Rio de Janeiro; numerous in high grasslands of Serra do Itatiaia. Poorly known. Occurs in Aparados da Serra, Caparaó, Itatiaia, Serra da Canastra and Tijuca National Parks, and in Patrimônio Natural do Caraça Special Reserve.
Bibliography. Bauer & Pacheco (2000), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Lencioni (1996), Meyer de Schauensee (1982), Pichorim *et al.* (1996), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Souza (1999), Stotz *et al.* (1996), Teixeira *et al.* (1989).

Genus *TUMBEZIA* Chapman, 1925

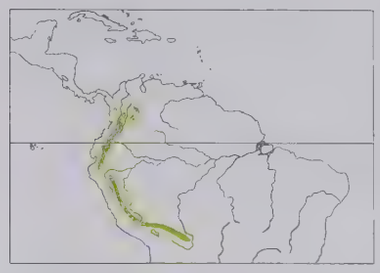
276. Tumbes Tyrant

Tumbezia salvini

French: Pitajo de Tumbes **German**: Gelbstirntyrann **Spanish**: Pitajo de Tumbes

Taxonomy. *Ochthoeca salvini* Taczanowski, 1877, Tumbes, Peru.
Affinities uncertain. Sometimes placed near similarly plumaged *Satrapa*; sometimes included in genus *Ochthoeca* on basis partly of similar syringeal characters, nesting habits and egg coloration. Monotypic.
Distribution. NW Peru, from Tumbes S to La Libertad.

Descriptive notes. 13·5 cm. Crown, lores and ear-coverts are dark grey; bold yellow frontal band and supercilium becoming paler and more whitish towards nape; generally grey or greyish-olive upperparts; wings dusky black, two broad white wingbars, secondaries and tertials edged white; tail blackish, outer rectrices edged white; throat and underparts entirely lemon-yellow; iris dark brown; bill short, black; legs black. Sexes alike. Voice. Call a mournful soft, somewhat musical, descending trill, "pitt-tit-tit-ttrrr" or "pttt-tiit-tiit-trrr-té", sometimes rising on final emphatic note; also a repeated "piit-tii-peeuur"; when excited, a repeated and rapid series of soft but distinct trilled notes, sometimes accentuated with higher-pitched and louder whistled note, "pttt-ttt-ttt, pttt-ttt-tttt, peeuur-ttt-péééü-pt-ttt-tttt-te" (Lambayeque); also, descending "pee-wtttt".
Habitat. Arid woodlands, frequently near acacia (*Acacia*) and mesquite (*Prosopis*) groves; often near dry watercourses. Usually below 200 m, locally at 540-800 m, and occasionally to 1000 m.
Food and Feeding. Insects. Frequently found in pairs. Fairly confiding. Perches at middle level, usually fairly erect, occasionally more horizontally; sometimes wags tail, with tail spread or fanned slightly. Often forages within 1-2 m of the ground, making short sallies to glean prey and to capture insects in air.
Breeding. No information.
Movements. Resident; occasional records at higher altitudes suggest possibly some seasonal elevational movement.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Tumbesian Region EBA. Uncommon; uncommon to fairly common in El Angolo Hunting Reserve (at 540-800 m), within the Northwest Biosphere Reserve. Has been recorded in about seven localities, all except aforementioned site unprotected, but may also occur in Cerros de Amotape National Park (also within Northwest Biosphere Reserve). These two protected areas are so far little threatened, with some subsistence logging, livestock grazing and agriculture around local settlements. Within remainder of Tumbesian region, however, forest and riparian and scrub habitats are being rapidly destroyed, degraded and fragmented as a result of timber extraction, livestock grazing and agricultural conversion, and it is feared that virtually all lowland forest outside protected areas will soon be eliminated.
Bibliography. Barrio (1997), Best & Kessler (1995), Clements & Shany (2001), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), García *et al.* (1998), Lanyon (1986a), Meyer de Schauensee (1982), Parker *et al.* (1996), Ridgely & Tudor (1994), Smith & Vuilleumier (1971), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977).



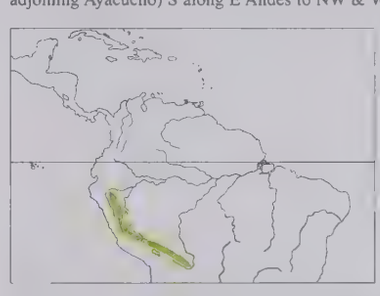
Genus *OCHTHOECA* Cabanis, 1847

277. Crowned Chat-tyrant

Ochthoeca frontalis

French: Pitajo couronné **German**: Kronenschmätzertyrann **Spanish**: Pitajo Coronado

Taxonomy. *Tyrannula frontalis* Lafresnaye, 1847, Pasto, Colombia.
Sometimes placed with *O. pulchella*, *O. diadema* and *O. jelskii* in a separate genus, *Silvicultrix*, but genetic and anatomical data indicate that this would make present genus paraphyletic. All four form a superspecies. *O. pulchella* and *O. jelskii* previously considered races of present species. Described race *orientalis* (from Ecuador) synonymized with nominate. Four subspecies recognized.
Subspecies and Distribution.
O. f. albidiadema (Lafresnaye,1848) - E Andes of Colombia (Bogotá).
O. f. frontalis (Lafresnaye, 1847) - W & C Andes of Colombia and both slopes in Ecuador.
O. f. boliviana Carriker, 1935 - Andes of C & S Peru (San Martín S to Huánuco, and Urubamba Valley in S Cuzco) and Bolivia (E slope from La Paz SE to Santa Cruz).
O. f. spodionota Berlepsch & Stolzmann, 1896 - Junín, W Cuzco (in Cordillera Vilcabamba) and adjoining Ayacucho, in C Peru.
Descriptive notes. 12·5-13 cm. Male nominate race has crown dark brown, bright yellow frontal band and long supercilium becoming white toward back of head; dark brown upperparts, dusky wings and tail with feathers edged dusky brown; throat whitish-grey, dark grey below, lower belly becoming whitish-grey, crissum and lower flanks dull cinnamon or dull rufous-buff; iris dark; bill black; legs black. Differs from *O. pulchella* in whiter supercilium, no wingbars, from *O. jelskii* in lack of rufous wingbars. Female has lighter crown, more extensive cinnamon-buff below. Juvenile is brighter overall, with brownish wash on flanks and belly, supercilium with buffy tinge, buffy wingbars.



Race *albidiadema* has forehead and supercilium all white; *boliviana* is greyer above, crissum whitish, usually one or two rufous wingbars; *spodionota* is like previous but supercilium shorter. Voice. Usually silent; occasionally a thin, high-pitched, descending trill, "te-tirrrrrrrrrr," often lasting several seconds.
Habitat. Elfin forest, montane forest borders, and scrubby thickets, usually in elevational zone 100-200 m below tree-line; also *Polylepis* woodland (Ecuador) and in dead bamboo on mossy ground. At 2800-4000 m, occasionally down to 1600 m, rarely to 1300 m.
Food and Feeding. Insects. Usually solitary, and rarely with mixed-species flocks. Inconspicuous and easily overlooked, usually perching low to the ground in undergrowth. Sallies to foliage and branches for flying insects; often flits to mossy limbs and trunks, rather than to foliage.
Breeding. Fledglings in Sept in Colombia and Jan in Bolivia (Cochabamba); juveniles in Apr in NW Ecuador and Nov in Peru (Huánuco). Nest an open cup, placed in cavity on cliff, among roots projecting from bank, in *Espeletia* shrub or in bush. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in all Andean protected areas in Ecuador and Peru and in the La Paz and Cochabamba provinces in Bolivia.
Bibliography. Carriker (1935), Chapman (1917c, 1921), Clements & Shany (2001), Cory & Hellmayr (1927), Fitzpatrick (1973), Fjeldså & Krabbe (1990), García *et al.* (1998), Hennessey & Gómez (2003), Hilty (2003), Hilty & Brown (1986), Lanyon (1986a), Meyer de Schauensee (1982), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Traylor (1985), Walker (2001).

278. Golden-browed Chat-tyrant

Ochthoeca pulchella

French: Pitajo à sourcils d'or **Spanish**: Pitajo Cejidorado
German: Gelbbrauen-Schmätzertyrann
Other common names: Yellow-browed Chat-tyrant

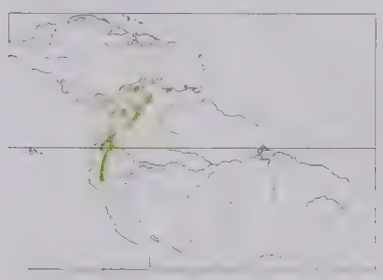
Taxonomy. *Ochthoeca pulchella* P. L. Sclater and Salvin, 1876, Tilotilo, Yungas of La Paz, Bolivia.
Sometimes placed with *O. frontalis*, *O. diadema* and *O. jelskii* in a separate genus, *Silvicultrix*, but genetic and anatomical data indicate that this would make present genus paraphyletic. All four form a superspecies. Formerly considered conspecific with *O. frontalis* and, later, with *O. jelskii*. Two subspecies recognized.
Subspecies and Distribution.
O. p. similis Carriker, 1933 - E Andes of Peru (S Amazonas S to Junín).
O. p. pulchella P. L. Sclater & Salvin, 1876 - S Peru (Cordillera Vilcabamba, in W Cuzco and adjoining Ayacucho) S along E Andes to NW & WC Bolivia.

Descriptive notes. 12 cm. Nominate race has dark grey-brown head and neck, darkest on crown, frontal band and long, narrow supercilium golden-yellow, paler behind eye; dark brown back, more rufescent on lower back and rump; wings and tail dark brown, two broad bright rufous wingbars; dark grey below, whiter on mid-belly, some rufous-buff on lower flanks, grey crissum; iris dark; bill black; legs black. Sexes alike. Juvenile has crown brown, buffy posterior supercilium, breast washed with olivaceous, belly and flanks ochraceous-buff. Race *similis* has ochraceous crissum. Differs from *O. jelskii* in having all-yellow supercilium, from *O. frontalis* also in rufous wingbars. Voice. Call a distinctive "te-tirrrr"; descending whine, "treeeee"; also "trrrr-rr-eeh-eh-errh-eehr-eeee", rising at end, or "trrr-rrr-rr-rrr-rrrr-eeee-rrr-rrr", especially at dawn. Occasionally clicks or snaps bill.
Habitat. Humid montane and scrubby forest borders; shady ravines, dark thickets, bamboo, and mossy forest. At 1700-2800 m.
Food and Feeding. Insects, including small beetles (Coleoptera). Usually occurs singly, occasionally in pairs, and most often not associated with mixed-species flocks. Often unobtrusive; perches low, flicks wings and tail. Sallies and gleans items, fluttering to strike prey from leaves or small branches; usually flies only short distances.
Breeding. Juvenile in Mar in Peru (Junín). No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common; probably often overlooked, as inconspicuous and not often seen. Present in all protected areas in its range, e.g. Machu Picchu Historical Sanctuary, in Peru, and Madidi National Park, in Bolivia.
Bibliography. Clements & Shany (2001), Cory & Hellmayr (1927), Davies *et al.* (1994), Fitzpatrick (1973), Fjeldså & Krabbe (1990), García *et al.* (1998), Hennessey & Gómez (2003), Hennessey, Herzog & Sagot (2003), Hinojosa *et al.* (1998), Koepcke (1970), Lanyon (1986a), Meyer de Schauensee (1982), Remsen (1985), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1985), Walker (2001), Zimmer (1937a).

279. Yellow-bellied Chat-tyrant

Ochthoeca diadema

French: Pitajo diadème **German**: Gelbbauch-Schmätzertyrann **Spanish**: Pitajo Diademado



Taxonomy. *Myiobius diadema* Hartlaub, 1843, Bogotá, Colombia.

On following pages: 280. Jelski's Chat-tyrant (*Ochthoeca jelskii*); 281. Slaty-backed Chat-tyrant (*Ochthoeca cinnamomeiventris*); 282. Rufous-breasted Chat-tyrant (*Ochthoeca rufipectoralis*); 283. Brown-backed Chat-tyrant (*Ochthoeca fumicolor*); 284. D'Orbigny's Chat-tyrant (*Ochthoeca oenanthoides*); 285. White-browed Chat-tyrant (*Ochthoeca leucophrys*); 286. Piura Chat-tyrant (*Ochthoeca piurae*); 287. Patagonian Tyrant (*Colorhamphus parvirostris*).

Sometimes placed with *O. frontalis*, *O. pulchella* and *O. jelskii* in a separate genus, *Silvicultrix*, but genetic and anatomical data indicate that this would make present genus paraphyletic. All four form a superspecies. Described race *meridana* (from Mérida, in Venezuela) considered indistinguishable from nominate; *cajamarcae* (from Cajamarca, in Peru) synonymized with *gratiosa*. Five subspecies recognized.

Subspecies and Distribution.

O. d. jesupi J. A. Allen, 1900 - Santa Marta Mts, in N Colombia.
O. d. rubellula Wetmore, 1946 - Sierra de Perijá, on Colombia-Venezuela border.
O. d. tovarensis Gilliard, 1940 - coastal range in N Venezuela (Aragua, Distrito Federal).
O. d. diadema (Hartlaub, 1843) - E Andes in W Venezuela and Colombia.
O. d. gratiosa (P. L. Sclater, 1862) - W & C Andes and W slope of E Andes of Colombia S to N Peru (Piura, Cajamarca).

Descriptive notes. 12-12·5 cm. Large-headed appearance, long rictal bristles. Nominate race has crown dark olive, yellow forehead and long supercilium becoming narrower and paler behind eye, lores blackish; upperparts olivaceous or brownish-olive, wings and tail dusky; yellow-olive below, light yellow on throat and belly, more olive on breast; iris dark brown, bill and legs black. Sexes alike. Juvenile has supercilium tinged ochraceous posteriorly, rufous wash on back, ochraceous vent. Race *jesupi* is virtually indistinguishable from nominate in field; *tovarensis* is also similar, but brighter yellow wash below; *gratiosa* has upperwing-coverts tipped dull rufous, flight-feathers edged rufous; *rubellula* has rufescent brown back and broad rufous edgings on wings. Voice. Call an accelerating trill, ending with separate lower note; song a thin rapid trill, e.g. "chiiiiiaaaaaiiiii", also much longer trill, c. 4-4·5 seconds, that slowly rises before dropping slightly at end; dawn song a fast, ascending trill, "prrrreeee" or "preeeeeee'sku`u`u`u", repeated at intervals of several seconds.

Habitat. Dense interior and undergrowth of humid montane forest, less often along shrubby forest borders near streams; generally not found in areas with bamboo. Mostly 1700-3100 m, rarely down to 800-900 m.

Food and Feeding. Insects, mostly small beetles (Coleoptera). Generally inconspicuous and infrequently seen; usually in pairs in dense undergrowth close to ground; sometimes forages near mixed flocks, but usually not joining them. Perches fairly erect, usually up to 5 m above ground in mossy understorey; frequent wing-flicking and tail-flicking, and aggressive behaviour. Frequently sallies, and gleans from low foliage or near ground, usually taking prey from foliage with audible snap of mandibles; items occasionally taken from twigs or the ground.

Breeding. Jan-Oct in Colombia and Mar-Dec in Ecuador. Nest details unclear, but reported as a mossy cup placed on bank. Clutch 4 eggs. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common; inconspicuous and often overlooked, possibly more common than it appears to be. Occurs in all protected areas in Andes of Ecuador except Cajas; also found in Sierra Nevada National Park, in Venezuela, and many localities in Colombia, e.g. Tambito Nature Reserve and Cueva de los Guácharos National Park.

Bibliography. Allen (1998), Baez *et al.* (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick (1973), Fjeldså & Krabbe (1990), García *et al.* (1998), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Sclater & Salvin (1879), Stotz *et al.* (1996), Traylor (1985), Williams & Tobias (1994).

280. Jelski's Chat-tyrant

Ochthoeca jelskii

French: Pitajo de Jelski **German**: Rostbürzel-Schmätzertyrann **Spanish**: Pitajo de Jelski

Taxonomy. *Ochthoeca jelskii* Taczanowski, 1883, Montaña de Nancho, Peru.

Sometimes placed with *O. frontalis*, *O. pulchella* and *O. diadema* in a separate genus, *Silvicultrix*, but genetic and anatomical data indicate that this would make present genus paraphyletic. All four form a superspecies. Formerly considered conspecific with *O. frontalis* and, later, with *O. pulchella*; possibly closest to former. Monotypic.

Distribution. SW Ecuador and NW Peru (S to Lima, in La Libertad crossing to E side of R Marañón W of C Andes).

Descriptive notes. 12-12·5 cm. Male has blackish-brown head, yellow frontal area and white supercilium; upperparts more rufous-brown than head; wings dusky, two strong rufous wingbars; tail dusky or brownish; grey below, paler belly tinged pale rufous, buffy crissum; iris dark; bill black; legs black. Differs from *O. frontalis* in having prominent rufous wingbars, and plumage generally browner above and paler grey below; from *O. pulchella* in white (not yellow) supercilium. Female is buffier below, especially on lower belly. Voice. Usually quiet; song a high-pitched and sharp "tseeeee", sometimes varied to "tseee-krrrr" or "tse-tsirrekerrr".

Habitat. Borders of montane forest and secondary woodland and adjacent shrubby stream borders; 1300-3400 m, generally at higher elevations towards S of range.

Food and Feeding. Insects. Usually found singly; occasionally follows mixed-species flocks. Usually sallies from low perch in vegetation, occasionally from ground.

Breeding. No information.

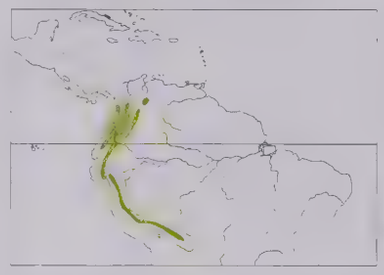
Movements. Resident.

Status and Conservation. Not globally threatened. Rare to uncommon and local; often overlooked, possibly more common. In Ecuador, appears more abundant in Sozoranga, Cariamanga and Utuana regions than elsewhere, e.g. fairly common near Utuana (Loja) in "Bosque de Hanne" Forest Reserve, which was recently afforded protection by Fundación Arcoiris and Fundación Jocotoco. Occurs also along entrance road at W edge of Podocarpus National Park, in Ecuador, and in Cutervo, in NW Peru.

Bibliography. Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick (1973), Fjeldså & Krabbe (1990), García *et al.* (1998), Koepcke (1970), Lanyon (1986a), Rasmussen *et al.* (1996), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1985), Zimmer (1937a).

281. Slaty-backed Chat-tyrant

Ochthoeca cinnamomeiventris



French: Pitajo noir **German**: Schiefermantel-Schmätzertyrann **Spanish**: Pitajo Negro
Other common names: Blackish Chat-tyrant (*nigrita*); Chestnut-belted/Maroon-belted Chat-tyrant (*angustifasciata* and *thoracica*)

Taxonomy. *Muscicapa cinnamomeiventris* Lafresnaye, 1843, Colombia, restricted to "Bogotá".

N race *nigrita*, nominate and S races (*angustifasciata* and *thoracica*) sometimes treated as three separate species, differing in plumage and vocalizations, apparently also with genetic differences between nominate and S races; treatment as conspecific based largely on constancy of plumage pattern. Further research required. Four subspecies recognized.

Subspecies and Distribution.

O. c. nigrita P. L. Sclater & Salvin, 1871 - Andes of Venezuela (Mérida, Táchira).
O. c. cinnamomeiventris (Lafresnaye, 1843) - Andes of SW Venezuela (W Táchira) and Colombia (from Antioquia and Santander) S to Ecuador (on W slope S to Chimborazo) and extreme N Peru.
O. c. angustifasciata Chapman 1926 - N Peru, from S Amazonas S to R Marañón, also E Cajamarca S to SW San Martín.
O. c. thoracica Taczanowski, 1874 - C & SE Peru (S from Pasco) S to N Bolivia (S to Cochabamba).

Descriptive notes. 12-13 cm; 11·9 g. Small and short-tailed, with short, thin bill, long rictal bristles. Nominate race has largely slaty or blackish head, short white supercilium; upperparts largely slaty or blackish-grey, wings perhaps slightly brown-tinged; tail narrow, blackish; throat and upper chest blackish, breast and belly deep chestnut, lower belly and crissum blackish; iris, bill and legs black. Sexes alike. Juvenile resembles adult. Races vary mainly in underpart coloration: *nigrita* has no chestnut below; in *thoracica* supercilium does not reach base of bill, wide band of deep chestnut across chest; *angustifasciata* is similar but with somewhat narrower chestband. Voice. Persistent and loud calls often audible above rushing torrents; common vocalization a sharp "dzzweee-yew", often repeated, also high-pitched "chew"; dawn song consists of same note followed by 3-4 "tseet" notes. Call of *thoracica* higher-pitched "tseeeeeyeeee", reminiscent of a *Pipreola* fruiteater; *nigrita* infrequently gives rather loud, buzzy, slightly descending whistle.

Habitat. Montane forest and edge and second growth, most often in shrubs and other dense vegetation in stream ravines; 1600-3000 m, locally to 3300 m, rarely down to 900 m.

Food and Feeding. Insects. Usually singly or in close pair, notably sedentary; does not accompany mixed-species flocks. Perches upright and low in edge of dense or shady understorey vegetation, usually by streams; inconspicuous (because of dark plumage), but voice often betrays its presence. Sallies, usually a short distance, and gleans, frequently returning to same perch.

Breeding. Jan-Aug in Colombia, where eggs in Feb (Huila) and juveniles Feb-Aug and birds with enlarged gonads in Oct (Boyaca); Feb-Aug in Peru, fledglings in Mar (Junín). Nest a mossy cup, placed among roots in crevice, bank, cliff or occasionally bush. No other information.

Movements. Resident.

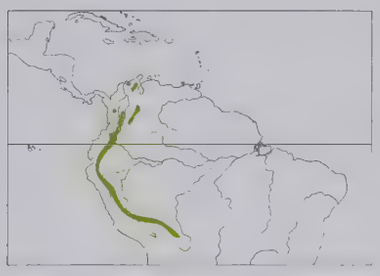
Status and Conservation. Not globally threatened. Fairly common. Very numerous in vicinity of Cerro Las Copas, in Venezuela. Occurs in all national parks in Andes of Ecuador; probably also in all national parks and other reserves in its range in Peru and Bolivia, e.g. Finca Merenberg, Tambito Nature Reserve and Cueva de los Guácharos National Park, all in Colombia, Guandera Biological Reserve and Podocarpus National Park, both in Ecuador, and Madidi National Park, in Bolivia.

Bibliography. Baez *et al.* (1997), Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fitzpatrick (1973), Fjeldså & Krabbe (1990), García *et al.* (1998), Hilty (2003), Hilty & Brown (1986), Krabbe *et al.* (1997), Lanyon (1986a), Meyer de Schauensee (1982), Olivares (1971), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Sclater & Salvin (1879), Stotz *et al.* (1996), Walker (2001), Williams & Tobias (1994), Zimmer (1937a).

282. Rufous-breasted Chat-tyrant

Ochthoeca rufipectoralis

French: Pitajo à poitrine rousse **Spanish**: Pitajo Pechirrufo
German: Orangebrust-Schmätzertyrann



Taxonomy. *F[luvicola] rufi-pectoralis* d'Orbigny and Lafresnaye, 1837, Ayopayo, Cochabamba, Bolivia.

Taxonomy within this species uncertain, owing to isolation of Andean valleys in which races occur, and inadequate documentation of extent and frequency of intermediates; in S of range, variation from *centralis* to *tectricialis* and nominate apparently clinal; current treatment maintained pending further study. Seven subspecies recognized.

Subspecies and Distribution.

O. r. poliogastra Salvin & Godman, 1880 - Santa Marta Mts, in N Colombia.
O. r. rubicundula Wetmore, 1946 - Sierra de Perijá, on Colombia-Venezuela border.
O. r. rufopectus (Lesson, 1844) - E Andes of Colombia.
O. r. obfuscata J. T. Zimmer, 1942 - C & W Andes of Colombia S to N Peru (Piura, Cajamarca, Amazonas, possibly NW San Martín).
O. r. centralis Hellmayr, 1927 - NC Peru (S La Libertad, Ancash, Huánuco).
O. r. tectricialis Chapman, 1921 - SC Peru (Pasco S to Cuzco).
O. r. rufipectoralis (d'Orbigny & Lafresnaye, 1837) - SE Peru (Cuzco, N Puno) and W Bolivia (La Paz, Cochabamba).

Descriptive notes. 13-14 cm; 13 g. Distinctive. Nominate race has head sooty brown, conspicuous white frontal band and long broad supercilium; upperparts brown or sooty brown; wings and tail blackish, faint rufous or cinnamon-buff edgings on tertials and secondaries, outermost rectrices narrowly edged white; chin and throat greyish, lower throat and chest dark orange-rufous, belly white; iris dark brown; bill short, thin, black; legs black. Sexes alike. Juvenile is similar to adult. Races vary mainly in wing markings, also coloration of underparts: *obfuscata* has rufous wingbar

(occasionally two), pale edges of tertials more prominent; *centralis* is like previous, chestband darker; *tectricialis* is variable, largely intermediate between previous and nominate in respective contact zones; *poliogastra* has crown brown, hardly differing from back, broad rufous on wing, narrow and paler breastband, greyer below; *rubicundula* and *rufipectus* both very similar to last. Voice. Song an abrupt "tjrt-tjrrrrt-tjt-trrrt", "chic-chic-chica" or "ch-brrr, ch-brrr, ch-brrr", usually doubled; also, faint "cleeoo" and rapid series of "pt" notes ending with two "cleeoo" notes; dawn song "tirip, wee-eeuww, tirip, weeeeuw" and so on; some trilled vocalizations recall voice of Neblina Tapaculo (*Scytalopus altirostris*). Occasionally gives clucking sound. Wings produce whirring sound.

Habitat. Borders of open cloudforest and humid montane and *Polylepis* forests, often along roads; occasionally stunted forest and shrubby slopes near tree-line, and riparian thickets in semi-arid zone. Mostly 2000-3600 m, rarely to 4100 m.

Food and Feeding. Insects. Usually found singly or in pairs, and sometimes accompanies mixed flocks; often highly territorial. Perches conspicuously in alert and upright manner, usually less so when actively foraging; frequently jerks, appearing perky. Makes short sallies into air, though more frequently to foliage where adroitly hover-gleans prey mostly from upper leaf surfaces.

Breeding. Jan-Sept in Colombia; juvenile in Apr in Ecuador; nest in Oct (Puno) and juvenile in Nov (Huánuco) in Peru. Nest a moss cup on rock ledge, often sheltered by stunted trees. No other information.

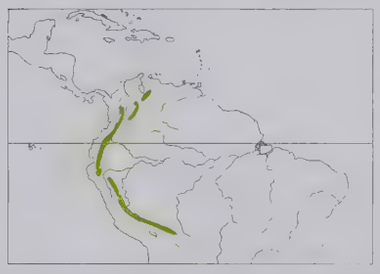
Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common. In Ecuador, less abundant on W Andean slopes than on E ones. Occurs in most national parks within its range, but not in wettest zones; present in e.g. Guandera Biological Reserve, Podocarpus National Park and Utuana forests (recently protected by Fundación Arcoiris and Fundación Jocotoco), all in Ecuador, Machu Picchu Historical Sanctuary, in Peru, and Madidi National Park, in Bolivia.

Bibliography. Baez *et al.* (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fitzpatrick (1973), Fjeldså & Krabbe (1990), García *et al.* (1998), Hennessey, Herzog & Sagot (2003), Hilty (2003), Hilty & Brown (1986), Hinojosa *et al.* (1998), Meyer de Schauensee (1982), Moynihan (1979), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Schulenberg & Servat (2001), Stotz *et al.* (1996), Todd & Carriker (1922), Walker (2001), Williams & Tobias (1994), Zimmer (1930, 1937a).

283. Brown-backed Chat-tyrant

Ochthoeca fumicolor



French: Pitajo à dos brun **German**: Fahlbrauen-Schmätzertyrann **Spanish**: Pitajo Dorsipardo

Taxonomy. *Ochthoeca fumicolor* P. L. Sclater, 1856, Bogotá, Colombia.

It has been suggested that brighter race *superciliosa*, occurring adjacent to dark nominate race (but apparently separated by Táchira Depression), may be a separate species. Birds from Cochabamba may represent a separate race, as yet undescribed. Five subspecies currently recognized.

Subspecies and Distribution.

O. f. superciliosa P. L. Sclater & Salvin, 1871 - Andes of W Venezuela (Trujillo, Mérida, E Táchira).
O. f. fumicolor P. L. Sclater, 1856 - Andes of SW Venezuela (S Táchira) and N part of E cordillera in Colombia.
O. f. ferruginea J. T. Zimmer, 1937 - N part of C & W Andes of Colombia.
O. f. brunneifrons Berlepsch & Stolzmann, 1896 - C & W Andes of Colombia S to N & C Peru.
O. f. berlepschi Hellmayr, 1914 - SE Peru (Cuzco, Puno) and W & C Bolivia (La Paz, Cochabamba).

Descriptive notes. 14·5-16 cm; 17 g. Flat-headed appearance. Nominate race has frontal area and supercilium whitish, becoming more ochraceous behind eye; crown warm brown; back rufescent brown, becoming more rufous-brown towards rump; wings dusky or blackish, two prominent rufous wingbars, lower one more conspicuous; tail dusky to blackish, white outer webs of outer rectrices; throat and lower face greyish; underparts cinnamon-rufous, crissum buff; iris dark; bill black; legs black. Female is somewhat paler below. Juvenile is warmer brown, lacks grey on chin. Races vary mainly in cinnamon tones of breast and supercilium: *superciliosa* is brightest, with rufous supercilium and breast, fading to buff on belly centre; *brunneifrons* has long, conspicuous buff supercilium, strong wingbars; *berlepschi* has rather short, narrow, dirty whitish supercilium, birds from Cochabamba have browner crown; *ferruginea* resembles previous but more white in outer tail. Voice. Usually quiet, but call a high-pitched "tsiu"or soft "prip"; clear whistled "kleeeip" when foraging or perched; at dawn, partners sing a rhythmic duet "plee, pliter'ter, phl'ter'tew", chattery, up to 12 phrases, slowing at end; when excited a sharp "keek-kee-keek" or "keek-tede-keek" repeated from perch, or sometimes at night with accompanying wing-whirring.

Habitat. Shrub-bordered pastures, montane forest and semi-humid *Polylepis* woodland at or above tree-line, and open *páramo* with *Espeletia*. At 2200-4200 m, rarely down to 1800 m and up to 4400 m.

Food and Feeding. Insects. Usually singly, or pair-members widely scattered; often territorial. Perches on thick branches, usually near main stem, or clings to main stem, also prominent perches on bushtops and fence posts; generally conspicuous, often confiding. Sallies varying distances to ground, foliage or air, sometimes returning to same perch sometimes changing perch and moving considerable distance; occasionally hover-gleans; spreads wings and tail widely and for long periods upon landing.

Breeding. Season Feb-Sept in C & E Andes of Colombia, and nest in Dec (Boyaca); nest and eggs in Mar in Venezuela; moult (presumed post-breeding) in Nov in Peru (Huanuco) and Jan in Bolivia (Cochabamba). During territorial disputes makes short wobbling flights and wing-whirring. Nest a fur-lined cup, placed low down in *Espeletia* shrub. No other information.

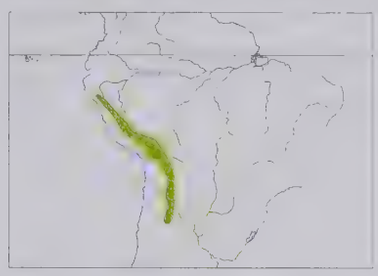
Movements. Resident; some seasonal or local altitudinal movement suspected because of records at lower elevations.

Status and Conservation. Not globally threatened. Fairly common to common. Occurs in all national parks at appropriate elevations in Colombia and Ecuador (except Cotacachi-Cayapas), Río Abiseo National Park in N Peru, and all national parks in S Peru and in La Paz and Cochabamba provinces in Bolivia.

Bibliography. Baez *et al.* (1997), Butler (1979), Chapman (1917c, 1921), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick (1973), Fjeldså & Krabbe (1990), García *et al.* (1998), Hilty (2003), Hilty & Brown (1986), Kessler & Herzog (1998), Koepcke (1970), Meyer de Schauensee (1982), Olivares (1963), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Schulenberg & Servat (2001), Sclater & Salvin (1879), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Varty *et al.* (1986), Vuilleumier & Ewert (1978), Walker (2001), Williams & Tobias (1994), Zimmer (1930, 1937a).

284. D'Orbigny's Chat-tyrant

Ochthoeca oenanthoides



French: Pitajo d'Orbigny **German**: Graurücken-Schmätzertyrann **Spanish**: Pitajo Canela

Taxonomy. *F[luvicola] OEnanthoides* d'Orbigny and Lafresnaye, 1837, La Paz, Bolivia.

Races overlap, with birds tending to exhibit intermediate characters, in extreme S Peru and N Chile. Two subspecies recognized.

Subspecies and Distribution.

O. o. polionota P. L. Sclater & Salvin, 1870 - Peru (from La Libertad S along W Andes to Cuzco and N Puno) and extreme N Chile (Arica).
O. o. oenanthoides (d'Orbigny & Lafresnaye, 1837) - S Peru (Titicaca Basin, in Tacna), N Chile (Arica), W Bolivia (S from La Paz) and NW Argentina (S to La Rioja).

Descriptive notes. 14·5-17 cm. Nominate race has white frontal band and very long, broad whitish-buff supercilium; crown greyish or greyish-brown, blackish mask; upperparts greyish-brown or greyish; wings and tail duskier, weak greyish-cinnamon wingbar, tertials edged greyish-cinnamon, secondaries narrowly edged white, outer web of outermost rectrix white; throat greyish, chest dusky cinnamon, becoming deep cinnamon on lower belly, vent white or greyish-white; iris dark brown; bill black; legs black. Differs from *O. fumicolor* in having less distinct wingbars, generally paler above, whiter supercilium, paler throat. Sexes alike. Juvenile has supercilium creamy white. Race *polionota* is generally darker, sooty grey above, with brighter white supercilium and blacker mask, weaker wingbars, darker underparts, vent washed cinnamon. Voice. Usually not very vocal; song a rhythmical loud "reek a teek a reek a teek a" lasting 1-3 seconds, and often gives excited song-like notes; call a sharp "kvee"; contact note "chit" or "chic-chit", repeated at intervals of 3-5 seconds.

Habitat. Arid montane forest and woodlands (e.g. *Puya*, *Gynoxys* and *Polylepis*), often on slopes and in ravines and near rushing streams; also on rocky slopes with bunch-grass and very scattered bushes and fence posts; usually tied to woodland. At 2800-4500 m; locally down to 2000 m (Argentina).

Food and Feeding. Insects. Usually alone or in pairs. Perches upright and conspicuously on dead branches, bushtops or fence posts; flies down to take insects from the ground, often returning to same perch.

Breeding. In Bolivia, eggs and fledglings in Dec (La Paz) and juveniles in Jan (La Paz), Nov (Cochabamba) and Feb (Chuquisaca); pair feeding two chicks in Feb in Argentina. Nest an open cup placed in cavity on cliff. No further information.

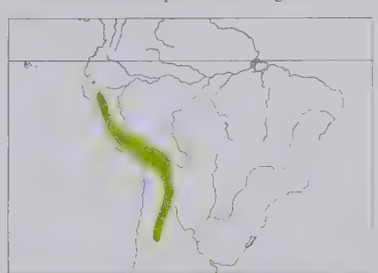
Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in Machu Picchu Historical Sanctuary and Huascarán National Park, in Peru, Madidi National Park, in Bolivia, and Los Cardones National Park, in Argentina.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chapman (1921), Clements & Shany (2001), Cory & Hellmayr (1927), Fitzpatrick (1973), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), García *et al.* (1998), Jaramillo (2003), Johnson (1967), Koepcke (1970), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Ordano (1998a), de la Peña (1988), Quiroga *et al.* (1998), Ridgely & Tudor (1994), Rocha & Peñaranda (1995), Rocha & Quiroga (1998), Stotz *et al.* (1996), Walker (2001), Zimmer (1930, 1937a).

285. White-browed Chat-tyrant

Ochthoeca leucophrys



French: Pitajo à sourcils blancs **German**: Graubauch-Schmätzertyrann **Spanish**: Pitajo Gris

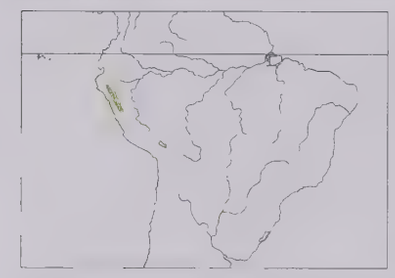
Taxonomy. *F[luvicola] leucophrys* d'Orbigny and Lafresnaye, 1837, Sicasica, La Paz, Bolivia.

Probably forms a superspecies with *O. piurae*, and these two are sometimes considered conspecific. Race *urubambae* possibly better merged with *interior*. Six subspecies currently recognized.

Subspecies and Distribution.

O. l. dissors J. T. Zimmer, 1940 - extreme S Ecuador and N Peru (upper Marañón Valley).
O. l. interior J. T. Zimmer, 1930 - highlands of C Peru (Huánuco, Pasco).
O. l. urubambae J. T. Zimmer, 1937 - highlands of C & S Peru (Junín S to NE Ayacucho and Cuzco).
O. l. leucometopa P. L. Sclater & Salvin, 1877 - W Peru (Ancash) S to N Chile (Arica, Tarapacá).
O. l. leucophrys (d'Orbigny & Lafresnaye, 1837) - highlands of Bolivia.
O. l. tucumana Berlepsch, 1906 - highlands of NW Argentina (Salta S to San Juan).

Descriptive notes. 14·5-15 cm. Overall the greyest chat-tyrant. Nominate race has conspicuous white frontal area and long and broad supercilium; blackish mask, dark grey or greyish-brown crown; upperparts slightly paler than crown, faint cinnamon tinge on lower back and rump; wings duskier, two indistinct cinnamon wingbars; tail dusky, outer web of outermost rectrices white; pale grey below, paler on belly, crissum whitish; iris dark; bill black; legs black. Sexes alike. Juvenile tinged brownish, with conspicuous wingbars. Race *tucumana* differs from nominate in more distinct cinnamon on wings, lower back and rump, slightly paler grey below; *leucometopa* is darker above, no cinnamon,



remiges edged whitish; *urubambae* resembles previous, but slightly less dark on crown; *interior* is on average slightly darker above than previous; *dissors* is similar to last, but not quite so dark.
Voice. Vocalizes frequently; call a piercing "queeuw", sometimes "keeu keukeukeukeu" in flight; "tee teeti" when alarmed.
Habitat. Arid montane forest, *Polylepis* woodland and shrubby stream borders, especially ravines, gorges or slopes with grasses and herbs; often found near water. Mainly 2000-3500 m, locally down to sea-level; occasionally to 4000 m in Peru.
Food and Feeding. Insects. Usually singly or in pairs. Usually conspicuous, with slender though upright posture; often jerks or flicks wings and tail. Sallies for insects from top of low bushes and herbs, returning to prominent perch, or from the ground.
Breeding. Probably Oct-Jan in Peru; Nov-Feb in Argentina. Nest found in Argentina, an open cup made of small twigs, lined with feathers (probably from bird itself), white hairs and tiny bits of wool, external diameter 11 cm, height 8 cm, internal diameter 6 cm, depth 6 cm; concealed within grass clump 1·7 m above small stream on side of ravine; contained 1 egg. No other information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in Machu Picchu Historical Sanctuary and Huascarán National Park, in Peru, and Madidi National Park, in Bolivia.
Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chapman (1921), Clements & Shany (2001), Cory & Hellmayr (1927), Fitzpatrick (1973), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), García *et al.* (1998), Jaramillo (2003), Johnson (1967), Koepcke (1970), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001), Zimmer (1930, 1937a).

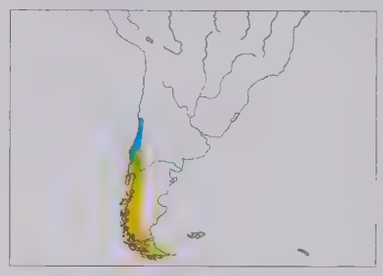
286. **Piura Chat-tyrant**

Ochthoeca piurae

French: Pitajo de Piura **German**: Buntflügel-Schmätzertyrann **Spanish**: Pitajo de Piura

Taxonomy. *Ochthoeca piurae* Chapman, 1924, Piura, Peru.
Probably forms a superspecies with *O. leucophrys*, and sometimes considered conspecific. Monotypic.
Distribution. W slope of W Andes from Piura S to Ancash, in NW Peru.

Descriptive notes. 12 -12·5 cm. Has crown and face dark brown, conspicuous white frontal band and long supercilium; back brown, lower back and rump dusky brown; wings duskier blackish, two broad rufous wingbars, white edges of tertials and secondaries; tail dusky brown, outer web of outer rectrices edged white; throat white or whitish, breast and upper belly greyish, lower belly and vent whitish-grey, crissum white; iris dark brown; bill black; legs black. Differs from *O. leucophrys* in much smaller size. Sexes alike. Juvenile undescribed. Voice. Call a thin "tchiitt", sometimes extended into soft, descending trill lasting 1-3 seconds "tchiitt-chtt-t-t-t-t-t-t-t-t" (Lambayeque).
Habitat. Arid montane-forest edge and hillside scrub and riparian thickets, at 1200-3300 m.
Food and Feeding. Unknown. Diet presumably insects. Usually singly or in pairs.
Breeding. Unknown.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Tumbesian Region EBA. Recorded at five localities in NW Peru: Palambla (in Piura), Porculla (Lambayeque), Samne (La Libertad), and Colcabamba and San Damián (Ancash). Small numbers can be found along W side of Porculla Pass road. At present, no protected areas exist within this species' very small range; continuing habitat clearance and degradation of montane scrub and riparian thickets, in conjunction with overgrazing, probably represent the main current threats.
Bibliography. Best & Kessler (1995), Clements & Shany (2001), Collar *et al.* (1994), Cory & Hellmayr (1927), Fitzpatrick (1973), Fjeldså & Krabbe (1990), Meyer de Schauensee (1982), Parker *et al.* (1996), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Zimmer (1937a).



Genus *COLORHAMPHUS* Sundevall, 1872

287. **Patagonian Tyrant**

Colorhamphus parvirostris

French: Pitajo de Patagonie **German**: Patagonienschmätzertyrann **Spanish**: Peutrén
Other common names: Patagonian Chat-tyrant, Small-billed Tyrant

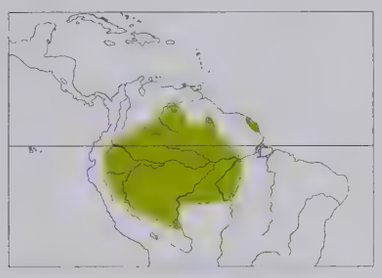
Taxonomy. *Myiobius parvirostris* Darwin, 1839, Santa Cruz, Chile.
Genus sometimes merged with *Ochthoeca*, to which appears most closely related according to morphological data. Formerly considered by some to be related to *Mecocerculus* or *Elaenia*. Monotypic.
Distribution. Breeds from SC Chile (from La Araucanía) and SW Argentina (from Neuquén and Río Negro) S to Tierra del Fuego; N to C Chile (Coquimbo) in non-breeding season.

Descriptive notes. 12-12·5 cm. Has head darkish grey with median band on crown blackish-grey fading to brownish-grey towards rear; rest of head medium grey, with slightly paler, whitish narrow eyering, blackish-grey ear patch; upperparts brownish-grey, more brownish on lower back and rump; wings and tail dusky brown, one or two cinnamon or cinnamon-rufous wingbars, secondaries narrowly edged rufous; throat and breast grey, gradually becoming buffy whitish on upper belly and whiter on lower belly, crissum buffy white or whitish; iris dark; bill short, black; legs black. Sexes alike. Juvenile is more rufous above without dark cap, darker below, abdomen more ochraceous. Voice. Distinctive call, frequent in breeding season, occasional at other times, a drawn-out, high, quavering and rather melancholy "pseeeuww"; song a long, high-pitched sibilant "seee".
Habitat. Borders of humid forest, including *Nothofagus*, *Quillaja saponaria* and *Maitenus boaria*, and shrubby openings; below 1000 m.
Food and Feeding. Insects. Frequently found singly or in pairs; generally inconspicuous; usually perches upright. Forages at varying levels, usually in treetops or quite high above ground during nesting period, generally lower (from low perches on herbs or bushes) in non-breeding season. Sallies for passing insects.
Breeding. Nov-Feb in Chile and Oct-Feb in Argentina. Nest cup-shaped, consisting of grass and moss, frequently attached to bamboo stem, usually low to ground inside *Nothofagus* forest; in Argentina, one nest had external diameter 13 cm, height 15 cm, internal diameter 5·1 cm, depth 3·5 cm, placed 4 m above ground in tree (hidden by leaves), another 1·5 cm from ground, with total diameter 11 cm, height 6 cm, internal diameter 6 cm, depth 3 cm. Clutch 3 eggs. No information on incubation and fledging periods.
Movements. Austral migrant. Post-breeding movement N, to as far as C Chile (Coquimbo); leaves breeding grounds in Mar, returns in Oct.
Status and Conservation. Not globally threatened. Rare to uncommon. Abundance decreases in extreme S parts of range. Occurs in all national parks within Chilean fjordlands, e.g. Puyehué National Park.
Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Casas *et al.* (1990), Chesser & Marín (1994), Clark (1986), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Cracraft (1985), Fjeldså & Krabbe (1990), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Joseph (1996), Marín (2004), Marín *et al.* (1989), Meyer de Schauensee (1982), Narosky & Salvador (1998), de la Peña (1988), Ridgely & Tudor (1994), Saibene (1988), Stotz *et al.* (1996), Vuilleumier (1985), Wetmore (1926).

PLATE 37 ➤

PLATE 37

inches 3
cm 8



Genus *OCHTHORNIS* P. L. Sclater, 1888

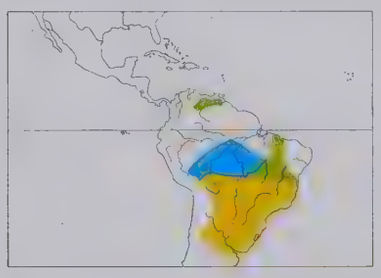
288. Drab Water-tyrant

Ochthornis littoralis

French: Moucherolle riverain **German**: Weißbrauentyrann **Spanish**: Mosquerito Guardarríos

Taxonomy. *Elainea littoralis* Pelzeln, 1868, Borba, Rio Madeira, Brazil.
Genus merged with *Ochthoeca* by some authors, but separate generic status supported by morphological and anatomical evidence and differences in behaviour and habitat. Monotypic.
Distribution. Amazonian S Colombia, S Venezuela (Amazonas, Bolívar) and S Guyana to E Ecuador, E Peru, N Bolivia and NW & NC Brazil; also N French Guiana and extreme NC Brazil (NE Amapá).

Descriptive notes. 13-13·5 cm; 13·4 g. Generally rather nondescript. Plumage is sandy brown above, crown and lores darker, rump paler, faint whitish supercilium; wings and tail dusky brown; underparts generally paler sandy brown than upperparts; iris dark; bill and legs blackish. Sexes alike. Voice. Usually quiet; call a weak, whistled "fwoit" or "fweet"; pair-members duet with rapid and excited sputtered warbling "weechidle-chee", repeated 4-6 times, often accompanied by wing-fluttering.
Habitat. Along tropical rivers and margins, especially near steep banks, exposed roots, or piles of debris; invariably found near water, especially large rivers. Sea-level to 600 m.
Food and Feeding. Insects. Usually singly or in pairs; often confiding, sometimes repeatedly allowing close approach and then flying only to short distance. Sallies to air or drops to shore for prey, typically from low perch above water; moves vertically with changing water levels, usually maintaining typical perch height of up to 1 m above surface level.
Breeding. Apr-Oct (Peru). Nest an open cup of grass stems, rootlets and mud, placed 3 m above river edge or in steep riverbank, often on hard mud ledge under log or overhang. Clutch 3-4 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common, but sometimes thinly spread along rivers. Occurs in Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Tinigua National Park, in Colombia, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Beni and Pilón Lajas Biosphere Reserves and Madidi National Park, all in Bolivia, and Rio Cristalino Forest Reserve and Tapajós National Park, both in Brazil.
Bibliography. Allen (1995), Alves & Soneghet (1999), Blake (1950, 1962), Chapman (1917c), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Fitzpatrick (1980c, 1981), Friedmann (1948), Hennessey, Herzog, Kessler & Robinson (2003), Hilty (2003), Hilty & Brown (1986), Lanyon (1986a), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Sick (1993, 1997), Schulenberg *et al.* (2001), Smith & Vuilleumier (1971), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977).



Genus *SATRAPA* Strickland, 1844

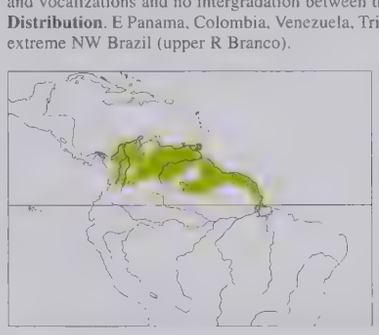
289. Yellow-browed Tyrant

Satrapa icterophrys

French: Moucherolle à sourcils jaunes **Spanish**: Mosquero Cejiamarillo
German: Goldbrauentyrann

Taxonomy. *Muscicapa icterophrys* Vieillot, 1818, Paraguay.
Affinities uncertain; has sometimes been grouped with *Tumbezia* and *Myiozetetes* on basis of plumage similarities, but nest type, egg coloration and syringeal morphology provide no obvious taxonomic clues. Monotypic.
Distribution. Breeds locally in C Venezuela, also N & E Bolivia and C & E Brazil S to N & E Argentina, Paraguay and Uruguay; S populations also move N to S part of Amazon Basin in non-breeding season.

Descriptive notes. 15-16·5 cm; 20 g. Has conspicuous and contrasting bright yellow supercilium and dark greyish-olive mask, crown and nape; upperparts dark olive; wings dusky black, two greyish-white wingbars, remiges (especially tertials) edged greyish-white; tail dusky, white outer web of outer rectrices, notched; bright yellow below, olive wash on side of breast; iris dark; bill rather short and narrow, black; legs short, blackish. Female is paler overall than male, notably on supercilium and throat; throat and breast mottled with olive. Juvenile has narrow upper wingbar, olive spots on breast. Voice. Normally silent; very mild but sharp "whee" heard, also very low double "cheep" during brood-feeding; song reported as rising laughter-like "whuee...whee whee whee whee whee".
Habitat. Semi-open edges of forests, lakes, fields and marshy areas. Mostly below 500 m N of R Orinoco; mostly below 2000 m elsewhere, locally to 2600 m (Bolivia).
Food and Feeding. Insects. Usually singly, less often in pairs. Perches with upright posture on bushes, hedgerows or trees; makes short sallies or, more often, gleans from foliage, trunks or branches.
Breeding. Jun-Sept in Venezuela (fledging period in Sept), Oct-Jan in Brazil and Bolivia and Aug-Feb in Argentina. Nest a shallow open cup of rootlets and twigs placed in bush or in fork of tree (e.g. *Ceiba*), one in Argentina with external diameter 12 cm, height 9 cm, internal diameter 7 cm, depth 5 cm, 1·5 m from the ground. Clutch normally 3 eggs, sometimes 2 or 4; incubation period 15-16 days; fledging period 15 -20 days. Nests parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Austral migrant. Post-breeding retreat from S breeding areas, generally wintering N closer to equator; e.g. uncommon during austral winter in Peru along river and forest edges in Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved zone. Sometimes roosts in large flocks with *Tyrannus tyrannus* and *Griseotyrannus aurantioatrocristatus* during migration.
Status and Conservation. Not globally threatened. Uncommon to fairly common; locally common. Typically breeds in habitats of human-populated areas, but occurs also in many national parks and other protected areas, especially in S of range; these include, among others, two national parks in Bolivia, two in Paraguay, Cerro Corá National Park, in Uruguay, and Costanera Sur Ecological Reserve and San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), both in Argentina.
Bibliography. Babarskas *et al.* (2003), Barrows (1883), Bates & Parker (1998), Belton (1985), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Cruz & Andrews (1989), Di Giacomo (2004), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Friedmann (1927), Hayes (1995), Hilty (2003), Joseph (1996), Klimaitis & Moschione (1987), Lanyon (1986a), López (1997), Lowen *et al.* (1996), Mason (1985), Meyer de Schauensee (1966, 1982), Miserendino (1998), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Navas & Bó (1993a), Nores *et al.* (1983), de la Peña (1987, 1988, 1995), Ridgely & Tudor (1994), do Rosário (1996), Sclater (1888), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Traylor & Fitzpatrick (1982), Wetmore (1926).



Genus *FLUVICOLA* Swainson, 1827

290. Pied Water-tyrant

Fluvicola pica

French: Moucherolle pie **German**: Elsterwassertyrann **Spanish**: Viudita Pía

Taxonomy. *Muscicapa pica* Boddaert, 1783, French Guiana.
May form a superspecies with *F. albiventer*; often considered conspecific, but differs in plumage and vocalizations and no intergradation between the two. Monotypic.
Distribution. E Panama, Colombia, Venezuela, Trinidad and the Guianas S to upper E Orinoco and extreme NW Brazil (upper R Branco).

Descriptive notes. 12·5-13·5 cm; 11-16 g. Prominent rictal bristles. Male has white head, contrasting black hindcrown and nape; upperparts mixed black and white, some white mottling on back, scapulars broadly white, entire rump white; wings black, tertials narrowly tipped white; tail black, narrowly tipped white; all white below; iris dark; bill sharply hooked at tip, black; legs black. Female is similar, but hindcrown and back mixed brownish. Juvenile has pattern of adult but much duller, with brown replacing black. Voice. Call a nasal, buzzy "zhweeoo" or "dreeap" (sometimes accompanied by vertical jump of c. 1 m), heard most often at dawn or dusk; also soft "pik", like sound of bubble bursting; song a repeated, buzzy "choo-wer".
Habitat. Around freshwater marshes, ponds and lakes, sometimes out into adjacent open areas, corrals and gardens. Mostly below 450 m, locally to 1000 m.
Food and Feeding. Insects. Usually singly or in scattered pairs. Conspicuous and tame. Usually forages in the open, gleaning prey from foliage and emergent vegetation over water; also flies to the ground or water to snatch items; occasionally runs short distances, or sallies from ground for flying prey. Frequently seen on floating vegetation.
Breeding. Apr-Nov in Venezuela and Colombia; Jun-Oct, once in Jan, in Trinidad. Nest, built by both sexes, a large oval or spherical ball, side entrance near top, made of dried grass, plant down and leaves, with feather lining, placed conspicously at end of branch, on stump or in small bush, often low over water. Clutch 2-3 eggs; incubation and brood-feeding by both parents; no information on incubation and nestling periods. Sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to locally common. May be slowly increasing its range in Panama and perhaps elsewhere. Occurs in Tinigua National Park, in Colombia.
Bibliography. Anon. (1998a), Bangs & Penard (1918), Butler (1979), Chapman (1894), Cory & Hellmayr (1927), Cruz & Andrews (1997), ffrench (1991), Friedmann (1948), Friedmann & Smith (1950), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Herklots (1961), Hilty (2003), Hilty & Brown (1986), Lefebvre *et al.* (1992), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Sick (1993, 1997), Skutch (1985), Smith, W.J. Cock-tailed Tyrant (*Alectrurus tricolor*); 295. Strange-tailed Tyrant (*Alectrurus risora*); 296. Streak-throated Bush-tyrant (*Myiotheretes striaticollis*); 297. Santa Marta Bush-tyrant (*Myiotheretes pernix*); 298. Smoky Bush-tyrant (*Myiotheretes fumigatus*); 299. Rufous-bellied Bush-tyrant (*Myiotheretes fuscorufus*); 300. Red-rumped Bush-tyrant (*Cnemarchus erythropygius*); 301. Chocolate-vented Tyrant (*Neoxolmis rufiventris*); 302. Rufous-webbed Bush-tyrant (*Polioxolmis rufipennis*).

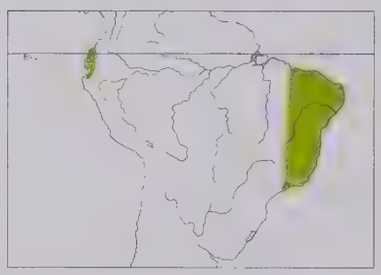
291. Black-backed Water-tyrant

Fluvicola albiventer

French: Moucherolle à dos noir **Spanish**: Viudita Dorsinegra
German: Schwarzrücken-Wassertyrann

Taxonomy. *Muscicapa albiventer* Spix, 1825, Bahia, Brazil.
May form a superspecies with *F. pica*; often considered conspecific, but differs in plumage and vocalizations and no intergradation between the two. Monotypic.
Distribution. Breeds from NC & E Brazil (lower Amazon region and Maranhão E to Rio Grande do Norte, S locally to Mato Grosso do Sul and W São Paulo) S to E Bolivia, Paraguay, N Argentina (S to La Rioja, Santa Fe and Buenos Aires) and W Uruguay; also occurs in W Amazonian Brazil, SE Peru and N Bolivia in non-breeding season.



Descriptive notes. 14 cm. Male has very distinctive plumage, with black upperparts and white underparts: white head, and contrasting black hindcrown and nape; mostly black above, with variable narrow white wingbars, and narrow white band across rump; variable white feather tips and edges to tail; pure white below; iris dark; bill and legs black. Female similar to male. Voice. Call "tika".
Habitat. Marshes and nearby shrubby vegetation, and beside rivers and oxbow lakes; mostly below 1000 m.
Food and Feeding. Insects. Usually quite bold, sometimes even inquisitive. Forages on or near ground, often moving out on to floating and emergent vegetation, frequently cocking and fanning its tail; flight fast and low.
Breeding. Oct-Feb in Argentina. Performs prenuptial flights. Nest a sphere with side opening near top, entrance concealed by "porch", rather loosely constructed from small twigs 0·5-1 cm in thickness and small stems with leaves, lined with feathers and plant down, one in Argentina 11 cm tall and 7 cm wide, with entrance 6·5 × 5 cm; placed low down, near or over water. Clutch 2-3 eggs; incubation period 12-14 days, fledging period 10-15 days. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Partial migrant. Some post-breeding migration W into W Amazonian Brazil, SE Peru and N Bolivia, with a few records from NE Peru (N to Loreto); vagrant in Ecuador.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in a number of national parks and other protected areas; has been recorded in Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone in non-breeding season.
Bibliography. Babarskas *et al.* (2003), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Fitzpatrick (1980c, 1985a), Friedmann (1927), Hayes (1995), Joseph (1996), Klimaitis & Moschione (1987), Maillard & Lindo (1998), Miserendino (1998), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), Oren & Parker (1997), de la Peña (1987, 1995, 1997), Ridgely & Tudor (1994), Robinson (1997), Schubart *et al.* (1965), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984), Wetmore (1926), Zimmer (1937a).

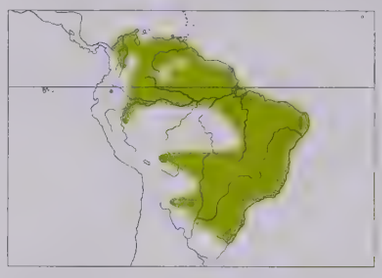
292. Masked Water-tyrant

Fluvicola nengeta

French: Moucherolle aquatique **Spanish**: Viudita Enmascarada
German: Graurücken-Wassertyrann
Other common names: Ecuadorian Water-tyrant (*atripennis*)

Taxonomy. [*Lanius*] *Nengeta* Linnaeus, 1766, Brazil.
Races geographically very remote from each other, sometimes suggested as representing two distinct species. Two subspecies recognized.
Subspecies and Distribution.
F. n. atripennis P. L. Sclater, 1860 - W Ecuador (S from Esmeraldas) S to extreme NW Peru.
F. n. nengeta (Linnaeus, 1766) - E Brazil from Maranhão E to Rio Grande do Norte, S to Minas Gerais, São Paulo and Rio de Janeiro.

Descriptive notes. 14·5-15 cm. Plumage is mostly white, with contrasting black eyestripe, black wings and white-tipped black tail; back tinged brownish-grey; iris dark, bill and legs black. Sexes similar. Race *atripennis* has blacker wings with tertials fringed white. Voice. Call a sharp "kirt!", often given in flight; song a repeated, soft "dewdelewdel-dewdel"; pair-members occasionally chatter together.
Habitat. Lowland semi-open shrubby areas near fresh water, especially in marshy areas and rice fields in lowlands; along shores of ponds, rivers and streams; occasionally in adjacent open areas. Mostly below 300 m; locally to 800 m, rarely to 1300 m.
Food and Feeding. Insects. Usually singly or in pairs, generally tame and conspicuous. Forages mainly on or near ground; runs on floating vegetation; makes short aerial sallies, quick dashes, and upward strikes to snap at insect prey along water's edge.
Breeding. Virtually unknown. Displaying birds face each other with tail spread and raised, bobbing up and down; male sometimes fans tail and spreads wings to display black underside. Nest is a messy ball of grasses and stems, with a side entrance.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common. Appears to be spreading S in Brazil as a result of deforestation; since 1950s recorded at a number of new localities (e.g. Rio Botanical Garden and, later, Zoological Garden, Catete Palace gardens, and Sernambetiba, Marambaia and other places). Tolerant of converted habitat and has relatively large range, within which it occurs in many national parks and other protected areas.
Bibliography. Alves & Pereira (1998), Butler (1979), Cracraft (1985), Develey (2004), Fitzpatrick (1980c, 1981, 1985a), Forrester (1993), Lo (1994), García *et al.* (1998), Ihering (1900), Marques & Alves (2000), Meyer de Schauensee (1982), Pacheco & Simon (1995), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodrigues & Santos (2000), Schubart *et al.* (1965), Sick (1993, 1997), Silveira *et al.* (2003), Stotz *et al.* (1996), Willis (1991b).



Genus *ARUNDINICOLA* d'Orbigny, 1840

293. White-headed Marsh-tyrant

Arundinicola leucocephala

French: Moucherolle à tête blanche **Spanish**: Viudita Cabeciblanca
German: Weißkopf-Wassertyrann

Taxonomy. *Pipra leucocephala* Linnaeus, 1764, Surinam.
Genus related to *Fluvicola* and sometimes merged with it; anatomical evidence and behaviour, however, suggest that separate generic treatment is more appropriate. Monotypic.
Distribution. N & E Colombia and N & C Venezuela E to Trinidad and the Guianas, S irregularly to E Ecuador, NE Peru, N & E Bolivia, N Argentina, Paraguay and SE Brazil.

Descriptive notes. 12·5-13 cm; 10-16·3 g. Male has white head (slightly bushy-crested) and throat contrasting sharply with blackish-brown or dark chocolate-brown rest of plumage; iris dark brown, eyes prominent; upper mandible blackish, lower mandible paler with yellow at base; legs black. Female has white forecrown, greyish-brown upperparts, darker wings and tail, whitish below, whitest on throat, mottled ashy brown across breast, sides and flanks; bare parts as male. Voice. Usually quiet, occasionally a high, sharp "sedik!"; low "dew-de-lewde" repeated at short intervals in courtship flight.
Habitat. Freshwater marshes, ponds and damp grass in *llanos*, also marshy areas along larger rivers and river islands; mostly below 500 m.
Food and Feeding. Insects. Generally conspicuous, especially male; perches erect. Sallies short distances from posts or low branches over water to air, or briefly to ground, for prey, immediately returning to elevated perch. Rarely descends to ground in manner of *Fluvicola*, and rarely fans or cocks tail.
Breeding. Jun-Nov in Venezuela and Jan-Apr and Jul-Oct in Trinidad; Jan-Mar in Colombia; Oct-Feb in Brazil and Oct-Jan in Argentina. Performs prenuptial flight. Nest, built by both sexes, a ball of grass with side opening near top, entrance concealed by "porch", placed low in bush or rushes near or over water. Clutch 2-4 eggs; incubation and chick-feeding by both sexes, no information on periods. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Resident; occasional wanderers reported from NE Peru and NE Ecuador (along R Napo), possibly associated with rapid turnover and succession in appropriate habitat of river islands.
Status and Conservation. Not globally threatened. Fairly common to locally common. Much of its habitat remains in relatively pristine condition within its large range, throughout which it occurs in many national parks and other protected areas.
Bibliography. Genus *ALECTRURUS* Vieillot, 1816

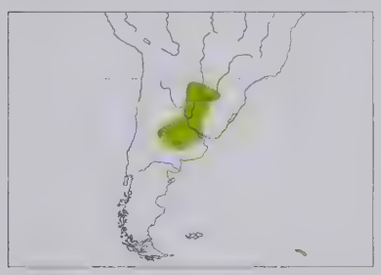
294. Cock-tailed Tyrant

Alectrurus tricolor

French: Moucherolle petit-coq **German**: Hahnenschwanztyrann **Spanish**: Yetapá Chico

Taxonomy. *Gallita tricolor* Vieillot, 1816, Paraguay.
Genus appears to be most closely allied to *Fluvicola* and *Arundinicola*. Monotypic.
Distribution. N & E Bolivia (Santa Cruz), S Brazil (S Mato Grosso E to Minas Gerais and Rio de Janeiro, S to São Paulo), NE Paraguay and NE Argentina (Misiones, Corrientes).

Descriptive notes. 12 cm, breeding-plumaged male to 19 cm. Male has white or whitish face; mostly black above, with grey on rump (black feathers brown-fringed in fresh plumage), white shoulders and patch on secondaries; tail extraordinary, wide, stiff central rectrices twisted 90 degrees so that vanes in vertical position, remaining rectrices laterally compressed against central ones, mostly frayed near tip; mostly white below, black patch on each side of chest forming partial collar; iris dark brown; bill mostly yellowish, some dusky coloration on culmen, lower mandible generally paler; legs grey. Female is mottled brown above, wings darker brown, tail dark brown, short, and normal in shape; throat white, underparts whitish, often tinged buff, some brown on chest sides forming partial collar. Immature male resembles female. Voice. Mostly silent; weak "tic-tic-tic" by male during aerial courtship.
Habitat. Large expanses of open, grassy habitats, especially *campo*, *cerrado* and humid savanna; in tall grass that has not been recently burned or heavily grazed; occasionally occupies shrubby margins adjacent to open grass or near water. Mostly below 1100 m.
Food and Feeding. Arthropods. Often gregarious, even during breeding; large aggregations of female-plumaged birds sometimes seen. Conspicuous; while perched, often jerks tail upwards and



then lowers it slowly at 1-second intervals, accompanied by wing-flick. Forages with aerial hawking, sally-gleaning or hover-gleaning against shrubs or grass stalks; peculiar, insect-like wingbeats, often making audible buzzy sound.
Breeding. Aug-Nov; timing of breeding may vary with onset of rains. Male displays by rising slowly into air from 5 m up to 100 m with exaggerated fast, fluttery wingbeats, and alternating tail position between straight down and cocked well above horizontal. Nest a neat grassy cup, hidden on or near ground. No other information.
Movements. Resident; possibly partially migratory or nomadic.
Status and Conservation. VULNERABLE. Uncommon to locally common; very local, largely because of rarity of undisturbed habitat, especially tall grass; numerous only in protected areas. Estimated global population of at least 10,000 individuals; continuing to decline, and no recent reports from a large portion of its former range of c. 626,000 km², which is increasingly fragmented owing to native grassland being burned, drained and coverted for pasture, eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations and agriculture (encouraged by government incentives). Normally disappears from burnt areas, but has been observed feeding on the ground in recently burnt areas. By 1993, two-thirds of *cerrado* region in C Brazil had been heavily or moderately altered, leading to a catastrophic loss of range in Brazil and Argentina (where the species has not been recorded since 1979, despite intensive searches). Few undisturbed areas remain outside protected areas, and these may soon be degraded by spreading fires and overgrazing or disappear completely through agricultural conversion. The species remains common only in undisturbed grasslands, e.g. Gama-Cabeça de Veado Environmental Protection Area, São Miguel Wildlife Sanctuary and Brasília, Emas and Serra da Canastra National Parks, all in Brazil. It occurs also in a few scattered protected areas in Goiás, Distrito Federal, Minas Gerais and Paraná, in Brazil, Beni Biosphere Reserve, in Bolivia, and San Rafael and San Luis National Parks, Tapytá Private Nature Reserve, and Sombrero Private Reserve, in Paraguay.
Bibliography. Anon. (2003h), Brace *et al.* (1997), Bucher & Nores (1988), Canevari *et al.* (1991), Capper *et al.* (2000), Cavalcanti (1988), Chebez (1994), Collar *et al.* (1994), Cory & Hellmayr (1927), Descourtilz (1983), Dubs (1992), Hayes (1995), Lanyon (1986a), Lowen *et al.* (1996), Machado *et al.* (1998), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Navas & Bó (1988), Parker *et al.* (1991), Pearman & Abadie (1995), de la Peña (1988), Ridgely & Tudor (1994), Robbins *et al.* (1999), Short (1975), Sick (1993, 1997), Silveira (1998), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977), Willis & Oniki (1988c).

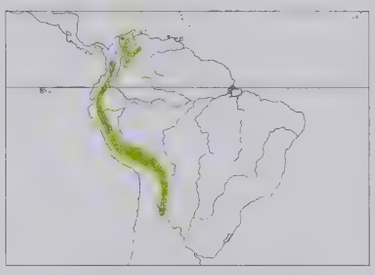
295. **Strange-tailed Tyrant**

Alectrurus risora

French: Moucherolle à queue large **Spanish**: Yetapá Acollarado
German: Rotkehl-Schleppentyrann

Taxonomy. *Muscicapa risora* Vieillot, 1824, Rio Grande do Sul, Brazil.
Genus appears to be most closely allied to *Fluvicola* and *Arundinicola*. Present species formerly placed in a monotypic genus, *Yetapa*, on basis primarily of exaggerated tail and elongated hallux; it does, however, have very similar plumage pattern to that of *A. tricolor*, with which it shares highly modified outer rectrices and numerous other derived features unique within the family. Monotypic.
Distribution. S Brazil (locally S Mato Grosso, São Paulo, Rio Grande do Sul), N Argentina (E Formosa and Misiones S to Córdoba and N Buenos Aires), E Paraguay and Uruguay.

Descriptive notes. 20 cm, breeding male 30 cm including tail. Male is mostly black above (feathers fringed brown in fresh plumage), with grey on rump, whitish scapulars, whitish tips of wing-coverts and edging on flight-feathers; tail greatly elongated, outer rectrices highly modified, twisted and lengthened, reduced to the shaft at base but with outer two-thirds of inner web becoming very broad, these feathers held perpendicular to and below rest of tail; throat bare, skin pinkish-red or pinkish-orange; broad breastband black, lower underparts white; iris brown; bill mostly pinkish-yellow, lower mandible generally more orange; legs dark grey, unusually long hind-claw. Non-breeding male may have narrower, shorter tail plumes, also has white-feathered (not bare) throat. Female is mottled brown above, outer two pairs of rectrices elongated and reduced, terminating in narrow racquets; throat white, underparts whitish, often tinged buff, with complete brown pectoral band. VOICE. Male call unknown; female call, when young close, is a repetitive, soft and weak whistled "thee-uu, schee-uu", final note descending.
Habitat. Savannas, marshes and damp grasslands; also shrubby areas. Below 500 m.
Food and Feeding. Insects. Perches conspicuously atop a tall grass stem, post or shrub, sallying both into the air and to grass for prey. Male flies slowly and weakly, whipping long tail up and down, or with elongated feathers carried straight down beneath rest of tail. Forms small loose flocks, including reported groups of up to 30 females, during non-breeding season.
Breeding. Eggs in Sept-Dec. Nest an open grassy cup, lined with feathers, hidden on or near ground. Clutch 3 eggs. No other information.
Movements. Resident; possibly a partial migrant in S part of range.
Status and Conservation. VULNERABLE. Rare to locally uncommon or fairly common. Estimated global population at least 10,000 individuals continuing to decline, and no recent reports from a large portion of its former range of c. 100,000 km², which is increasingly fragmented owing to native moist grassland being burned, drained and cultivated for pasture, eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations and agriculture (encouraged by government incentives). This species' preference for tall grasses suggests that it is intolerant of even biannual burning; pesticides, fertilizers and other chemicals are widely used and must have profound effects. Consequently, there has been a catastrophic loss of range in Brazil (last record in Rio de Janeiro in 1974, and even older records from Mato Grosso, São Paulo and Rio Grande do Sul), Uruguay (formerly uncommon breeder, but only one unconfirmed record since 1986) and Argentina (no recent records from several provinces or from Urugua-í Provincial Park, in Misiones, where all suitable habitat now destroyed). In Paraguay, it remains locally numerous, e.g. W of San Juan Bautista (Misiones), in Estancia San José and La Golondrina Private Nature Reserve (both in Presidente Hayes), and in three areas within San Rafael National Park; also recorded in the proposed Tacuara National Park. In Argentina, regularly recorded at El Bagual, Guaycolec and San Juan de Poriahú Private Reserves, and El Palmar and Mburucuyá National Parks, and in the 12,000-km² Iberá Natural Reserve, in Corrientes, where the largest known population was estimated at c. 23,000 birds in 1992; recent records indicate that numbers in Chaco and Formosa are considerably lower. A conservation award was recently given to study different management regimes and to raise public awareness at Mburucuyá National Park. Although the species is apparently resident throughout much of its range, seasonal movements have been noted in Buenos Aires and several of the Paraguayan records are thought to refer to migrants, making part of the population vulnerable to loss of either breeding or wintering habitats.
Bibliography. Bucher & Nores (1988), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Descourtilz (1983), Di Giacomo (2004), Di Giacomo & Di Giacomo (2004), Dubs (1992), Ericson & Amarilla (1997), Hayes (1995), Lanyon (1986a), Lowen *et al.* (1996), Meyer de Schauensee (1966, 1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Navas & Bó (1988), Pacheco & Gonzaga (1994), Pearman & Abadie (1995), de la Peña (1988), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977), Wege & Long (1995), Wetmore (1926).



Genus *MYIOTHERETES* Reichenbach, 1850

296. **Streak-throated Bush-tyrant**

Myiotheretes striaticollis

French: Moucherolle à gorge rayée **German**: Streifenkehl-Buschtyrann **Spanish**: Birro Grande

Taxonomy. *Taenioptera striaticollis* P. L. Sclater, 1853, Ecuador.
Genus sometimes placed near *Gubernetes* and *Muscipipra* on basis of anatomical and morphological characters; also, *Polioxolmis* and *Cnemarchus* have frequently been merged with this genus. Two subspecies recognized.
Subspecies and Distribution.
M. s. striaticollis (P. L. Sclater, 1853) - Sierra de Perijá and W Andes of Venezuela and Colombia S to N & C Peru (S to Apurímac and Arequipa).
M. s. pallidus Berlepsch, 1906 - E Andes in Peru (Cuzco, Puno), Bolivia and NW Argentina (S to Tucumán).

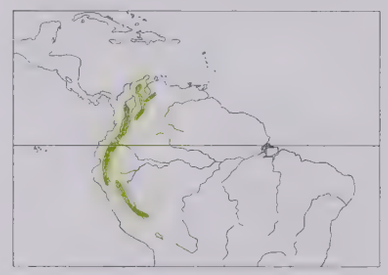
Descriptive notes. 21-23 cm; 64 g. Largest *Myiotheretes*. Plumage is brown above, crown and face darker, faint whitish supraloral stripe; wings dusky, cinnamon-rufous edging, wide cinnamon-rufous band along base of remiges (prominent in flight); tail dusky above, cinnamon below with outer third blackish; throat white with bold, heavy black streaks continuing to chest; upper chest pale brown, remaining underparts cinnamon-rufous; cinnamon underwing-coverts; iris dark brown; bill large, slightly hooked, blackish; legs blackish. Sexes alike. Race *pallidus* is somewhat smaller and paler than nominate, with slightly narrower streaks on throat. VOICE. Call a loud, rising whistle, "pseeeeee", with almost human quality; territorial call 2-4 loud, human-like whistles, "püéét wüéét sueet peeu"; infrequently heard song "tsi-seeee-rit" or "tsi-si-see-rit", reminiscent of that of *Tyrannus melancholicus*.
Habitat. Semi-open shrubby or grassy regions; in forest and woodland borders near cliffs, landslides or roadcuts; often partially cultivated terrain with shrubby areas and woodland patches; generally avoids extensively forested regions. At 1500-3700 m, mostly 2400-3400 m; occasionally down to 500 m in Peru (Arequipa) and Bolivia.
Food and Feeding. Insects and small vertebrates. Forages singly or pair-members widely spaced. Uses exposed and elevated (often highly so) perches; conspicuous. Sallies or, less frequently, drops to the ground for prey, sometimes travelling great distances; often returns to same perch.
Breeding. Jan-Jun in N Colombia (Perijá, Santa Marta Mts); nestlings in early Mar in Venezuela (Mérida). Nest reported as a messy cup placed under bridge or overhanging structure. No other information.
Movements. Resident; some seasonal altitudinal movement reported.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Never really common; given its tolerance of converted habitat, however, it is not threatened. Occurs in Sierra Nevada National Park, in Venezuela, Guandera Biological Reserve, in Ecuador, Machu Picchu Historical Sanctuary, in Peru, and Tarija National Park, in Bolivia.
Bibliography. Best *et al.* (1993), Canevari *et al.* (1991), Clements & Shany (2001), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hilty (2003), Hilty & Brown (1986), Lanyon (1986a), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Nores *et al.* (2000), de la Peña (1988, 2001a), Ridgely & Tudor (1994), Salaman (1994), Schulenberg & Servat (2001), Stotz *et al.* (1996), Varty *et al.* (1986), Vuilleumier (1994), Walker (2001), Zimmer (1930, 1937a).

297. **Santa Marta Bush-tyrant**

Myiotheretes pernix

French: Moucherolle des Santa Marta **Spanish**: Birro de Santa Marta
German: Santa-Marta-Buschtyrann

Taxonomy. *Ochthodiaeta pernix* Bangs, 1899, Macotama, Santa Marta Mountains, Colombia.
Genus sometimes placed near *Gubernetes* and *Muscipipra* on basis of anatomical and morphological characters; also, *Polioxolmis* and *Cnemarchus* have frequently been merged with this genus. This species formerly placed with *M. fumigatus* and *M. fuscorufus* in a separate genus, *Ochthodiaeta*. Monotypic.
Distribution. Santa Marta Mts, in N Colombia.
Descriptive notes. 18-21 cm. Has whitish supraloral stripe; dark brown above; wings darker, two pale cinnamon or rufous wingbars, rufous edges of inner flight-feathers; tail blackish, outer web of outer rectrix ferruginous or rufous-brown; throat white, narrowly and obscurely streaked dusky; underparts deep rufous, tinged olive on chest. Differs from *M. striaticollis* in smaller size, darker underparts, less cinnamon-rufous on tail. Sexes alike. VOICE. Call a short but loud, descending whistle, "weeuuu, heeuuu, heeuu", often repeated for up to a minute or longer.
Habitat. Shrubby borders of montane forest and secondary woodland, rarely in adjacent shrubby clearings, roadcuts, and overgrown hillsides; usually associated with forest edges. At 2100-2900 m.



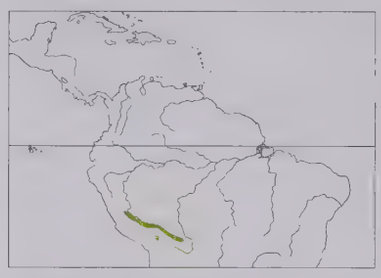
Food and Feeding. Insects. Usually alone or in pairs; occasionally with mixed-species flocks. Makes long sallies from top of bush or small tree; occasionally sallies within tree crown.
Breeding. Unknown.
Movements. Resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Santa Marta Mountains EBA. Uncommon. Global population of a few thousand individuals confined to area of 570 km² on N slope of Sierra Nevada de Santa Marta, where localized and fragmented. Recent records only from the San Lorenzo ridge, and it can be seen along lower elevations of the San Lorenzo road. Likely that other localities exist, but recent surveys in suitable habitat have not produced new records. Habitat declining owing to continuing forest conversion for marijuana plantations; only 15% of original vegetation in the Sierra Nevada de Santa Marta remains, although largely on N slope where this species occurs. Less significant threats are logging, burning, planting with exotic trees, e.g. pines (*Pinus*), and agricultural expansion, e.g. livestock grazing and coffee at lower altitudes. Remaining pristine habitats are protected within Sierra Nevada de Santa Marta and Tayrona National Parks and the Sierra Nevada de Santa Marta Biosphere Reserve, but these formal designations have so far not been effective. More work with local communities and regional institutions is needed in order to identify conservation and management strategies and establish priorities.
Bibliography. Anon. (1992), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Lanyon (1986a), Meyer de Schauensee (1982), Moynihan (1979), Negret (2001), Orejuela (1985), Ridgely & Tudor (1994), Salaman *et al.* (2002), Stattersfield & Capper (2000), Stotz *et al.* (1996), Vuilleumier (1994).

298. **Smoky Bush-tyrant**

Myiotheretes fumigatus

French: Moucherolle enfumé **German**: Rußbuschtyrann **Spanish**: Birro Ahumado

Taxonomy. *Tyrannula fumigata* Boissonneau, 1840, "Bogota," Colombia.
Genus sometimes placed near *Gubernetes* and *Muscipipra* on basis of anatomical and morphological characters; also, *Polioxolmis* and *Cnemarchus* have frequently been merged with this genus. This species formerly placed with *M. pernix* and *M. fuscorufus* in a separate genus, *Ochthodiaeta*. Four subspecies recognized.
Subspecies and Distribution.
M. f. olivaceus (Phelps. Sr & Phelps, Jr, 1953) - N Colombia (Sierra de Perijá) and W Venezuela (Cerro Tetari, in W Zulia, and R Chiquito, in S Táchira).
M. f. lugubris (Berlepsch, 1883) - Andes of W Venezuela (Trujillo S to N Táchira).
M. f. fumigatus (Boissonneau, 1840) - Colombia (except Santa Marta region) and N Ecuador.
M. f. cajamarcae (Chapman, 1927) - S Ecuador (Cañar) and Peru (S to Cuzco).



Descriptive notes. 18-20·5 cm. Dark and nondescript flycatcher, almost like a thrush (Turdidae). Nominate race has narrow white supercilium; uniform dark smoky brown above, wings and tail blackish, wing-coverts narrowly edged buffy; base of flight-feathers cinnamon on inner webs (prominent in flight); outer tail feathers edged whitish; dark below, chin and throat faintly mottled whitish, throat tinged ochraceous, undertail-coverts dingy buff; cinnamon underwing-coverts (prominent in flight); bare parts black. Sexes alike. Juvenile is similar to adult, but with cinnamon wingbars and remex edging, ochraceous vent. Race *lugubris* has reduced supercilium, and ochraceous crissum; *olivaceus* has supercilium dull greyish-white, brownish vent; *cajamarcae* is darker overall, with reduced supercilium. Voice. Relatively quiet; pre-dawn song a sustained series of whistled "cheea, cheea, cheea, chuéé", alternating 3 and 4 notes (one of the earliest pre-dawn singers in Venezuela); call a soft, descending whistle, "peeee".
Habitat. Middle growth and subcanopy of humid montane and elfin forests; often at edge of clearings and on shrubby slopes with scattered trees. Mostly occurs at 1800-3000 m, but occasionally up to 3600 m.
Food and Feeding. Insects. Found singly or in pairs, occasionally accompanying mixed flocks. Perches just below the canopy; alert and erect posture. Usually hawks prey from air or foliage, less frequently near or on the ground; sallies to snap insects from foliage or limbs.
Breeding. In Colombia, Jul-Aug in Sierra de Perijá and N & E Andes and Nov in Cundinamarca; fledglings in Feb in S Colombia (Cauca) and Jan in C Peru (Huánuco). No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common; rare in Peru. Occurs in Guaramacal and Sierra Nevada National Parks, in Venezuela, and all national parks in Andes of Ecuador and Peru S to Machu Picchu Historical Sanctuary.
Bibliography. Allen (1998), Baez *et al.* (1997), Butler (1979), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Lanyon (1986a), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Vuilleumier (1994), Walker (2001).

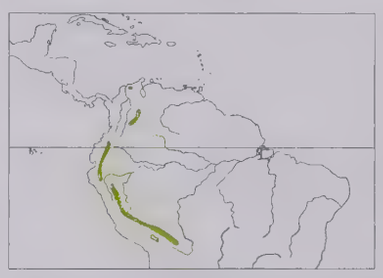
299. **Rufous-bellied Bush-tyrant**

Myiotheretes fuscorufus

French: Moucherolle à ventre fauve **Spanish**: Birro Ventrirrufo
German: Rostbinden-Buschtyrann

Taxonomy. *Ochthodiaeta fuscorufus* P. L. Sclater and Salvin, 1876, Tilotilo, Yungas, La Paz, Bolivia.
Genus sometimes placed near *Gubernetes* and *Muscipipra* on basis of anatomical and morphological characters; also, *Polioxolmis* and *Cnemarchus* have frequently been merged with this genus. This species formerly placed with *M. pernix* and *M. fumigatus* in a separate genus, *Ochthodiaeta*. Monotypic.
Distribution. SE Peru (Cuzco, Puno) and W Bolivia (La Paz, Cochabamba).

Descriptive notes. 18-19 cm. Has short whitish supercilium, dark eyeline; mainly brown above; wings blackish, two broad rufous wingbars, prominent rufous edging on inner flight-feathers (in flight, rufous in wings and dark terminal band on secondaries prominent); tail mostly blackish, outer web of outermost rectrix and edging on all inner webs cinnamon; throat whitish; underparts cinnamon, lower throat and chest faintly and obscurely streaked and mottled with brownish-olive; underside of tail dark with rufous down centre; iris dark; bill black; legs blackish. Voice. Dawn song 2-4 whistles followed by "pip pip pip pi-doo" notes. Clicks bill when agitated.
Habitat. Canopy borders of primary cloudforest (e.g. *Alnus*, Melastomataceae), adjacent secondary woodland, bamboo and other understorey vegetation types. Mainly 1900-3550 m.
Food and Feeding. Insects. In pairs or family groups; rarely accompanies mixed-species flocks. Often perches just inside the forest or at edge of clearings. Sallies to foliage and to the air; hawks or gleans insects from all levels, but mainly upper canopy.
Breeding. Unknown.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northeast Peruvian Cordilleras EBA and Bolivian and Peruvian Upper Yungas EBA. Rare to locally uncommon; common in Cocapata area (in Ayopayo province, NW of Cochabamba), in Bolivia. Occurs also on N side of the Abra Málaga road in Cuzco and in Machu Picchu Historical Sanctuary, both in Peru, and Madidi National Park, in Bolivia. Cloudforests within this species' range are in relatively pristine condition. Upper Yungas in Peru and Bolivia are still largely forested, as extensive tracts are undisturbed or protected in large reserves, such as the Tambopata-Candamo Reserved Zone and Madidi and Cotapata National Parks.
Bibliography. Clements & Shany (2001), Cory & Hellmayr (1927), Collar *et al.* (1994), Fjeldså & Krabbe (1990), García *et al.* (1998), Hennessey & Gómez (2003), Hennessey, Herzog & Sagot (2003), Herzog *et al.* (1999), Hinojosa *et al.* (1998), Lanyon (1986a), Meyer de Schauensee (1982), Remsen (1985), Ridgely & Tudor (1994), Schulenberg *et al.* (1984), Stotz *et al.* (1996), Vuilleumier (1994), Walker (2001).



Genus *CNEMARCHUS* Ridgway, 1905

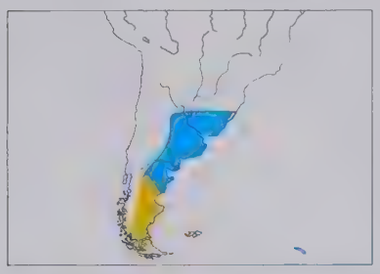
300. **Red-rumped Bush-tyrant**

Cnemarchus erythropygius

French: Moucherolle à croupion roux **Spanish**: Birro Culirrojo
German: Rostbürzel-Buschtyrann
Other common names: Red-rumped Ground-tyrant

Taxonomy. *Taenioptera erythropygia* P. L. Sclater, 1853, Verdecocha, Pichincha, Ecuador.
Was formerly sometimes placed in *Myiotheretes* or *Xolmis*. Most recent authors prefer retention of monotypic genus on basis of internal and external morphology. Races poorly differentiated. Two subspecies recognized.
Subspecies and Distribution.
C. e. orinomus Wetmore, 1946 - N & C Colombia (Santa Marta Mts and NE Andes).
C. e. erythropygius (P. L. Sclater, 1853) - S Colombia (Nariño) S to W & C Bolivia (La Paz, Cochabamba).

Descriptive notes. 20-23 cm. Large and unmistakable flycatcher. Has crown light grey with narrow black shaft streaks, forehead grizzled whitish, vague whitish supercilium; dark brownish-grey or brownish-slate above, contrasting rufous rump; wings dusky, white patch on tertials (especially conspicuous in flight); central tail feathers blackish, others rufous with terminal third black; throat streaked grey and white, becoming solid grey on upper breast, sharply rufous on belly; cinnamon underwing-coverts; iris dark; bill and legs black. Sexes alike. Juvenile has little white on forehead. Race *orinomus* very similar to nominate Voice. Usually quiet; call a short, blurry whistle, "wheeeu"; occasional shrill "kyeee" and higher-pitched "skyeik"; sometimes faint scratching sounds, "kerkkekkek".
Habitat. Montane scrub, *páramo* and *Polylepis* woodland; areas with scattered shrubs and low trees; often found in *puna* and grassland adjacent to scrubby areas. Mostly 2850-4000 m, occasionally to 4300 m.
Food and Feeding. Insects. Often found singly, less often in pairs or family groups. Usually conspicuous; perches on fences, boulders, bushes and wires; takes most prey by dropping to ground, less frequently sallies.
Breeding. Birds in breeding condition in Mar and Sept in Colombia; eggs in Nov in Peru (Puno). Nest an open cup placed low in bush. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally uncommon; rare in Colombia. Occurs in Las Cajas National Recreation Area and Guandera Biological Reserve, in Ecuador, Machu Picchu Historical Sanctuary, in Peru, and Madidi National Park, in Bolivia. Generally believed to occur in low densities, and is not frequently recorded.
Bibliography. Butler (1979), Carriker (1935), Clements & Shany (2001), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Hilty & Brown (1986), Kessler & Herzog (1998), Lanyon (1986a), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996).



Genus *NEOXOLMIS* Hellmayr, 1927

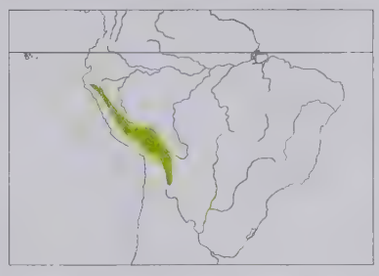
301. **Chocolate-vented Tyrant**

Neoxolmis rufiventris

French: Moucherolle à ventre bai **Spanish**: Monjita Chocolate
German: Hellschulter-Nonnentyrann

Taxonomy. *T[yrannus] rufiventris* Vieillot, 1823, Santa Lucía River, Uruguay.
Placed in *Myiotheretes* by early authors, and sometimes in *Xolmis* by more recent ones; syringeal morphology most similar to otherwise different *Gubernetes* and *Muscipipra*. Monotypic.
Distribution. Breeds SE Argentina (from S Río Negro) S, including extreme S Chile, to Tierra del Fuego; migrates N to C Argentina, Uruguay and SE Brazil.

Descriptive notes. 22-23 cm; 77 g. Large and handsome terrestrial flycatcher. Head is ashy grey, blackish fore-face and ocular region; upperparts brownish-grey; wing-coverts mostly white, greater coverts and tertials edged white or pale sandy brown (appearing silvery in field), secondaries rufous basally, broadly tipped white, remaining remiges black (in flight, wings look long and sharply pointed, white and rufous pattern striking); tail notched, black, outer web of outer rectrices white; throat and breast pure grey, lower breast becoming sharply cinnamon, cinnamon continuing to vent; iris dark; bill and legs black. Sexes alike. Juvenile has ear-coverts tinged rufous, breast, sides and upper belly broadly streaked dark grey. VOICE. Usually quiet; breeding male emits weak "bur-bit" at dawn and dusk from the ground or a rock.
Habitat. Semi-open and open grass and scrub-covered steppe with scattered tussocks and *Berberis* or *Verbena* bushes; hummocks of *Azorella* and crowberry (*Empetrum*), and agricultural fields or pastures. Mostly below 500 m, locally to 1200 m.
Food and Feeding. Insects, including large beetles (Coleoptera), also small vertebrates (lizards). Usually in widely spaced pairs, but in non-breeding season occurs in small flocks. Primarily terrestrial, but often perches on low bushes; mostly walking or running quickly, then pausing and standing erect on ground or low mound, nervously flicking wings and tail. Flight swift and direct, pair-members or small groups often chasing one another.
Breeding. Nov-Dec in Argentina. Nest a bowl-shaped cup, lined with grasses and feathers, diameter c. 10-10·4 cm, depth 5-6·9 cm; placed on ground, partially concealed by low shrub or tussock. Clutch 2-3 eggs. No other information.
Movements. After breeding, moves N to winter in NE Argentina (mostly Córdoba, Santa Fe and Entre Rios S to Río Negro and Buenos Aires), Uruguay and SE Brazil (Rio Grande do Sul).
Status and Conservation. Not globally threatened. Restricted-range species: present in Southern Patagonia EBA. Rare to uncommon. Fairly common around El Caín (S Río Negro) and Estancia Las Vegas (S Santa Cruz), in Argentina. Numbers may greatly fluctuate in S part of range, where absent in some years and abundant in others; alternatively, may be decreasing overall, as few recent reports of high local abundance. Much grassland has already been destroyed by grazing sheep, and only few protected areas exist, e.g. Tierra del Fuego National Park, in Argentina, and Magallanes National Reserve, in Chile.
Bibliography. Andors & Vuilleumier (1998), Araya & Chester (1993), Canevari *et al.* (1991), Clark (1986), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Cracraft (1985), Fjeldså & Krabbe (1990), Harris (1998), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Joseph (1996), Lanyon (1986a), Marín (2004), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1987, 1988, 1997), Ridgely & Tudor (1994), Ridgway (1905), Sick (1993, 1997), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Ridgely & Tudor (1994), Vuilleumier (1994).



Genus *POLIOXOLMIS* W. E. Lanyon, 1986

302. **Rufous-webbed Bush-tyrant**

Polioxolmis rufipennis

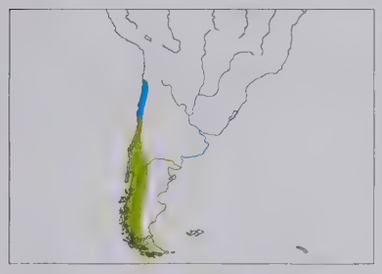
French: Moucherolle à ailes rousses **German**: Rostspiegel-Buschtyrann **Spanish**: Birro Alirrufo
Other common names: Rufous-webbed Tyrant/Ground-tyrant

Taxonomy. *Muscisaxicola rufipennis* Taczanowski, 1874, Maraynioc, Peru.
Formerly placed in *Cnemarchus* or *Xolmis*, and sometimes grouped with *Myiotheretes*; syringeal and other morphological evidence, however, indicates that current monotypic genus for this species is warranted. Two subspecies recognized.
Subspecies and Distribution.
P. r. rufipennis (Taczanowski, 1874) - Andes of Peru (S from S Amazonas, Cajamarca and Lambayeque) and W Bolivia.
P. r. bolivianus Fjeldså, 1990 - Andes of WC Bolivia S to extreme N Chile and NW Argentina.

Descriptive notes. 18-21·5 cm. Nominate race is uniform ashy grey above, pale grey or whitish supercilium and black eyeline; remiges cinnamon at base with dark tips, most extensive on primaries, tail dusky, outer web of outer rectrices white, inner webs of all but central pair cinnamon with dusky tips (wing and tail patterns striking in flight); throat paler and faintly streaked; paler ashy grey below, whitish vent and lower belly; underwing-coverts cinnamon; iris pale; bill long, with hooked tip, blackish; legs blackish. Sexes alike. Juvenile has belly more decidedly tinged buff. Race *bolivianus* is slightly smaller than nominate, browner grey, with narrower tailband. VOICE. Call a high-pitched "tree", given throughout day; alarm similar, but shorter.
Habitat. Semi-arid montane slopes near timber-line, especially grassland with cacti, low woodlands and low shrubs, and in *Polylepis* groves and adjacent scrub, usually where there are boulders or cliff faces. Sometimes in farms and gardens with trees present. Mostly 3000-4500 m, occasionally somewhat lower.
Food and Feeding. Insects. Usually singly or in pairs; conspicuous. Prefers perches on bushes, low trees or cliffs when hunting. Drops from perch to capture prey, less often runs or sallies in pursuit of prey; often hovers.
Breeding. In Peru, nesting in late Dec (Puno) and fledgling in Feb (Ancash). Performs a hovering-gliding display 10-12 m above ground. Nest a simple open cup, placed in tree (usually *Polylepis*) or the bromeliad *Puya raimondii*. Both adults recorded feeding two nestlings. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Appears to be generally rather rare, though locally fairly common. Recent information suggest that the species may be extending its range southwards. Possibly breeds in extreme N Chile: recently reported from Las Vicuñas National Reserve, N Chile, where, despite official protection, *Polylepis* woodland is still being damaged by firewood gathering, and may be threatened by proposed new tourist highway. Also occurs in Huascarán National Park, Machu Picchu Historical Sanctuary and Pampa Galeras National Reserve, all in Peru, and Sajama and Tunari National Parks, in Bolivia.
Bibliography. Canevari *et al.* (1991), Clements & Shany (2001), Cracraft (1985), Fjeldså (1990), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Hennessey, Herzog & Sagot (2003), Knapton (2002), Lanyon (1986a), Mazar Barnett, Clark *et al.* (1998), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1969, 1994), Walker (2001).

PLATE 38

inches 3
cm 8



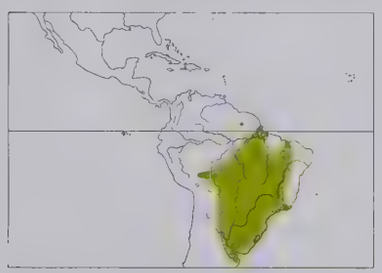
Genus *XOLMIS* Boie, 1826

303. Fire-eyed Diucon

Xolmis pyrope

French: Pépoaza oeil-de-feu **German**: Feueraugen-Nonnentyrann **Spanish**: Diucón

Taxonomy. *Muscicapa Pyrope* Kittlitz, 1830, Tomé, Bahía de Concepción, Chile.
Formerly placed in a monotypic genus, *Pyrope*, on basis of primary structure of male. Two subspecies recognized.
Subspecies and Distribution.
X. p. pyrope (Kittlitz, 1830) - C& S Chile (from Aconcagua) and SW Argentina (from Neuquén) S to Tierra del Fuego; winters in N Chile (S Antofagasta to Coquimbo).
X. p. fortis R. A. Philippi [Bañados] & Johnson, 1946 - Chiloé I, in SC Chile.



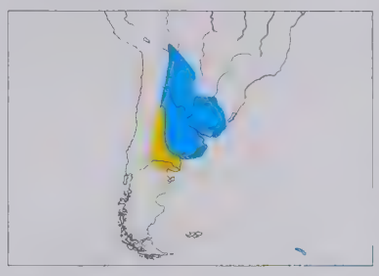
Descriptive notes. 18·5-21·5 cm. Head and back are uniformly dark grey; wings black with narrow grey edging; tail grey, outer feathers slightly paler; pale ashy grey below, throat whiter with faint grey streaking, belly greyish-white, vent white; iris bright red (sometimes inconspicuous); bill black; legs blackish. Sexes alike. Race *fortis* is slightly larger than nominate. Voice. Usually silent; call a low "tick tick;" also soft, plaintive "pit" or "whit", occasionally followed by musical double note.
Habitat. Edge of *Nothofagus* forest, woodland, and in shrubby clearings; also gardens, *Berberis* thickets, along hedgerows and small streams. Also in shrubby vegetation in Tierra del Fuego, where it seems to exploit more open habitats than on mainland of S Patagonia. Sea-level to 3050 m, mostly below 1000 m.
Food and Feeding. Insects; reported as also eating fruit, especially in winter. Perches conspicuously on tree branches; drops to ground after prey, less often sallies.
Breeding. Oct-Jan. Nest an open cup of small twigs and grass straws, lined with moss, wool, feathers, hair and similar; one in Argentina with external diameter 19 cm, height 13 cm, internal diameter 7·5 cm, depth 5·5 cm; placed in tree or bush, generally 2-3 m above ground. Clutch 2-3 eggs, sometimes 4; no information on incubation and fledging periods. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Mostly resident. S populations of nominate race migratory, move N in May, return in Nov.
Status and Conservation. Not globally threatened. Uncommon to fairly common or common. Occurs in Los Glaciares National Park, in Argentina, and La Campana National Park, in Chile.
Bibliography. Araya & Chester (1993), Belton (1985), Canevari *et al.* (1991), Chebez & Bertonatti (1994), Clark (1986), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2000, 2003), Estades (1999), Fjeldså & Krabbe (1990), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Joseph (1996), Marín (2004), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Tudor (1994), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Traylor (1977), Vuilleumier (1985, 1994), Wetmore (1926), Woods (1988).

304. Grey Monjita

Xolmis cinereus

French: Pépoaza cendré **German**: Bartstreif-Nonnentyrann **Spanish**: Monjita Gris

Taxonomy. *Tyrannus cinereus* Vieillot, 1816, hinterland of Rio de Janeiro, Brazil.
Two subspecies recognized.
Subspecies and Distribution.
X. c. cinereus (Vieillot, 1816) - Surinam, E Brazil (Amapá S to Rio Grande do Sul), NE Argentina (Misiones) and Uruguay.
X. c. pepoaza (Vieillot, 1823) - extreme SE Peru (E Madre de Dios) through E Bolivia to SC Brazil (S Mato Grosso do Sul), Paraguay and N Argentina (S to Tucumán and N Buenos Aires).



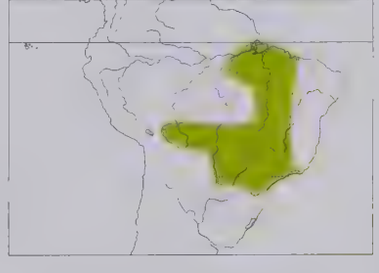
Descriptive notes. 22·5-23 cm; 50-61 g. Plumage is mouse-grey or dusky greyish above, broad white supraloral stripe, narrow white moustachial stripe, broader black submoustachial stripe; wings black, large white speculum at base of primaries (conspicuous in flight), wing-coverts tipped white, tertials edged white; tail black, broadly tipped whitish, outer rectrices tipped white; throat white, breast ashy grey, belly white; iris bright red; bill and legs black. Sexes alike. Juvenile has grey areas tinged brownish, otherwise similar to adult. Race *pepoaza* is very similar to nominate. Voice. Call a high and whistled "pééa"; song "pééehpéééh-ili, dew-dlee-ew", usually at dawn.
Habitat. Grassland and *cerrado*, occasionally around buildings, pastures, and outskirts of major cities; generally, no predilection for water. Often in city centres, sitting on television antennae, buildings and other artificial structures, during migration. Mostly below 1200 m.
Food and Feeding. Insects. Perches conspicuously on fences, bushes and wires; drops to ground after prey; less frequently sallies or runs along the ground. Often remains active even in heat of day. Flight fast, graceful; frequently flies with legs dangling.
Breeding. Little known. Nests found in Jan in Brazil, Dec in Argentina, and Oct and Nov in Urugauy; fledglings in Dec in Surinam. Undulating flight display, repeatedly looping before returning to perch. Nest an open cup of stems and straws, lined with roots, feathers and hair, placed in tree; holes also apparently used. Clutch 2-3 eggs; no information on incubation and fledging periods. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Mostly resident. Some S populations migratory; details uncertain.
Status and Conservation. Not globally threatened. Uncommon to common. Common in Sipaliwini Savanna Nature Reserve, in Surinam, and numerous across *cerrado* of Brazil (e.g. around Brasília); apparently less abundant in S part of range. Given its tolerance of converted habitat and its large range, it is not threatened, although rapid destruction of natural grassland and *cerrado* habitats throughout South America should be of concern. Occurs in many national parks and other protected areas.
Bibliography. Babarskas *et al.* (2003), Canevari *et al.* (1991), Clements & Shany (2001), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Fjeldså & Krabbe (1990), Haffer (1974), Haverschmidt & Mees (1994), Hayes (1995), Klimaitis & Moschione (1987), López (1997), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Navas & Bó (1993a), Novaes (1978a), de la Peña (1987, 1988), Ridgely & Tudor (1994), do Rosário (1996), Schubart *et al.* (1965), Short (1975), Sick (1993, 1997), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Traylor (1977), Vuilleumier (1994).

305. Black-crowned Monjita

Xolmis coronatus

French: Pépoaza couronné **Spanish**: Monjita Coronada
German: Schwarzkappen-Nonnentyrann

Taxonomy. *Tyrannus coronatus* Vieillot, 1823, Río Plata, Paraguay.
Monotypic.
Distribution. Breeds in C Argentina (San Luis, S Mendoza, La Pampa, S Buenos Aires, Río Negro); migrates N to as far as C Bolivia (W Santa Cruz), W Paraguay and extreme SE Brazil (W Rio Grande do Sul).



Descriptive notes. 21-22 cm. Has black crown bordered with broad white frontal band, supercilium and nuchal band; ear-coverts blackish; upperparts grey or brownish-grey; wings blackish, wing-coverts with white tips and edges, inner flight-feathers edged whitish, white stripe along base of flight-feathers (conspicuous in flight); tail blackish; entirely white below; iris dark; bill and legs black. Sexes similar, female slightly smaller than male. Voice. Song a soft, melodic "whut-whut, wheeeyr? whut".
Habitat. Open and semi-open areas with scattered bushes and low trees; mostly below 1500 m.
Food and Feeding. Insects. Usually perches on exposed shrub, tree or wire. Drops to ground to take prey, occasionally sallying or running. Generally wary.
Breeding. Sept-Dec. Nest an open cup of small twigs and grass, lined with wool, hair and feathers, placed in tree or bush, normally beneath a furnariid structure; one had top part elliptical, 14 × 23 cm, height 10 cm, interior 7·5 × 9·5 cm, depth 5 cm, placed 1·6 m above ground, near main trunk, 60 cm beneath old nest of cachalote (*Pseudoseisura*), another was similar to mockingbird (*Mimus*) nest but rather loose, smaller and flattened, external diameter 18 cm, height 9 cm, internal diameter 9 cm, depth 5·5 cm, 1·8 m from ground and 20 cm beneath an old furnariid construction. Clutch 2-3 eggs; incubation c. 16 days; fledging 13-16 days.
Movements. Migrant. After breeding, migrates N through remainder of Argentina (except Misiones) N to S Bolivia (W Santa Cruz), W Paraguay, Uruguay, and extreme S Brazil (W Rio Grande do Sul).
Status and Conservation. Not globally threatened. Uncommon to fairly common. May occasionally breed farther N, to W Tucumán.
Bibliography. Babarskas *et al.* (2003), Blake, E.R. (1953), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Di Giacomo (2004), Forrester (1993), Hayes (1995), Joseph (1996), Meyer de Schauensee (1982), Mezquida (2002), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1988, 1997), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Vuilleumier (1994).

306. White-rumped Monjita

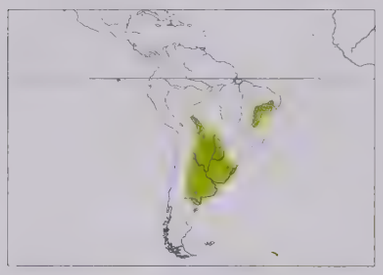
Xolmis velatus

French: Pépoaza voilé **German**: Weißbinden-Nonnentyrann **Spanish**: Monjita Velada

Taxonomy. *M[uscicapa] velata* M. H. K. Lichtenstein, 1823, São Paulo, Brazil.
Monotypic.
Distribution. NC to SE Brazil (lower Amazon E to Maranhão, S to Santa Catarina, extending W to S Mato Grosso and Mato Grosso do Sul), N & C Bolivia (Beni E to Santa Cruz) and NE Paraguay.

Descriptive notes. 19-20 cm. Head is mostly white, hindneck pearly grey; back brownish-grey, contrasting white rump and basal half of tail, terminal half of tail black; wings blackish, white band at base of flight-feathers (wingstripe in flight), patch of white on inner secondaries and tertials; all white below; iris dark; bill black; legs dusky blackish. Sexes similar. Voice. Mostly silent; dawn song an intense "jeww", repeated at intervals of 1-5 seconds; single whistle sometimes given at night.
Habitat. Savannas and semi-open areas with scattered bushes and trees, usually near water; often around ranch buildings and outskirts of towns. Below 1000 m.

On following pages: 307. White Monjita (*Xolmis irupero*); 308. Salinas Monjita (*Xolmis salinarum*); 309. Rusty-backed Monjita (*Xolmis rubetra*); 310. Black-and-white Monjita (*Xolmis dominicanus*); 311. Black-billed Shrike-tyrant (*Agriornis montanus*); 312. White-tailed Shrike-tyrant (*Agriornis andicola*); 313. Great Shrike-tyrant (*Agriornis lividus*); 314. Grey-bellied Shrike-tyrant (*Agriornis micropterus*); 315. Lesser Shrike-tyrant (*Agriornis murinus*).



Food and Feeding. Little known. Insects. Usually in pairs, perching conspicuously on fence posts, wires and tops of bushes; generally tame and approachable. Drops to the ground from low perch, or hovers. Often occurs with *X. cinereus*.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common. Occurs in many national parks and other protected areas throughout its reasonably large range; tolerant of converted habitat.
Bibliography. Bauer & Pacheco (2000), Cory & Hellmayr (1927), Dubs (1992), Forrester (1993), Haffer (1974), Hayes (1995), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Ridgely & Tudor (1994), do Rosário (1996), Schubart *et al.* (1965), Sick (1993, 1997), da Silva *et al.* (1997), Stotz *et al.* (1996), Vuilleumier (1994).

307. White Monjita

Xolmis irupero

French: Pépoaza irupéro **German**: Weißnonnentyrann **Spanish**: Monjita Blanca

Taxonomy. *T[yrannus] irupero* Vieillot, 1823, Río Plata, Paraguay.
Two subspecies recognized.
Subspecies and Distribution.
X. i. irupero (Vieillot, 1823) - E Bolivia, NE & C Argentina (S to Mendoza, San Luis and Río Negro), Paraguay, S & SE Brazil (Mato Grosso do Sul, Rio Grande do Sul) and Uruguay.
X. i. niveus (Spix, 1825) - E Brazil (Ceará and Pernambuco S to Bahia and N Minas Gerais).

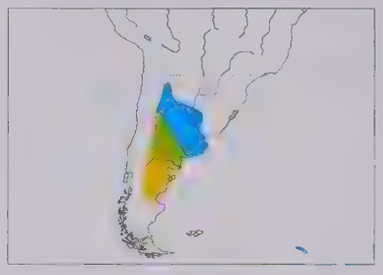
Descriptive notes. 17-18 cm. Male is pure white, except for black primaries, primary coverts and tip of notched tail; iris dark brown; bill and legs black. Female is tinged grey on back. Race *niveus* is slightly smaller than nominate, with wider black tailband. Voice. Usually silent; weak "ghiks" a whining "piew"; breeding male has soft, repeated dawn song, "preeeyp tooit preeeyp tooit".
Habitat. Savannas, open and semi-open grassland, and pastures with scattered trees and bushes, often along roads or near houses; often near marshes or open water. Mostly below 1000 m, but to 1300 m in Bolivia.
Food and Feeding. Insects. Perches conspicuously on treetops, bushes and wires; hides among dense and spiny vegetation if threatened or chased. Drops to ground in pursuit of insects; sometimes hovers (often hanging motionless for considerable periods) before swooping down to take prey.
Breeding. Sept-Dec in Argentina; nest in Nov and another being built in Aug in Uruguay. Nest a large open cup of twigs, grass and similar, lined with feathers and other soft material, 3 m above ground in tree hollow or in abandoned nest (mainly of furnariid); one nest in Argentina was 1·7 m up in hollow of willow (*Salix*), external diameter 6·5 cm, height 7 cm, internal diameter 4·5 cm, depth 4·5 cm, hollow was 25 cm in depth, maximum width 11 cm, entrance hole 15 cm tall and 7 cm across. Clutch 3-4 eggs; incubation period 12 days; fledging period 17 days. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to fairly common or common. Common in pantanal in Paraguay and Argentina; rare in E Brazil (race *niveus*). Occurs in many national parks and other protected areas throughout its range.
Bibliography. Babarskas *et al.* (2003), Canevari *et al.* (1991), Cory & Hellmayr (1927), Cracraft (1985), Di Giacomo (2004), Dubs (1992), Fjeldså & Maijer (1996), Friedmann (1927), Hayes (1995), Klimaitis & Moschione (1987), López (1997), Lowen *et al.* (1996), Meyer de Schauensee (1982), Miserendino (1998), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Narosky *et al.* (1990), Navas & Bó (1993a), Nores *et al.* (1983), de la Peña (1987, 1988), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Veiga *et al.* (2002), Zapata & Martínez (1972).

308. Salinas Monjita

Xolmis salinarum

French: Pépoaza de Salinas **German**: Weißnacken-Nonnentyrann **Spanish**: Monjita Salinera

Taxonomy. *Xolmis rubetra salinarum* Nores and Yzurieta, 1979, Argentina.
Initially described as a race of *X. rubetra*, but probably better treated as a distinct species. The two have sometimes been placed in genus *Neoxolmis*, but this treatment appears to be inappropriate. Monotypic.
Distribution. NC Argentina: E La Rioja, extreme S Catamarca, SW Santiago del Estero and NW Córdoba.



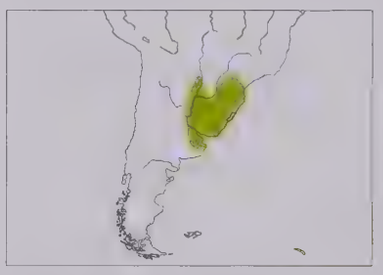
Descriptive notes. 16·5 cm. Male has prominent white supercilium; crown rufous, back rufous-brown, rump greyish-white; wings black, greater and median wing-coverts edged greyish-white, lesser coverts rufescent, tertials edged white; tail mostly black, outer web of three outer rectrices white; side of neck white with faint black streaks, underparts white; iris dark; bill and legs black. Female has neck more streaked. Differs from *X. rubetra* in smaller size, paler coloration, less streaking on neck and breast, very little rufous on flanks. Voice. Unknown.
Habitat. Semi-open scrubby vegetation on salty soils; 100-200 m.
Food and Feeding. Diet unknown, probably insects. Usually in pairs; also small flocks of up to 50 individuals during austral winter. Mainly terrestrial, but also perches on bushes.
Breeding. Unknown.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Locally uncommon to fairly common. Found in small numbers throughout year N of San José de las Salinas, near Salinas Grandes (NW Córdoba). This species' small range is cause for concern, but no other threats are currently known. Research required.
Bibliography. Canevari *et al.* (1991), Chebez (1994), Collar *et al.* (1994), Fjeldså & Krabbe (1990), Lanyon (1986a), Narosky & Salvador (1998), Narosky & Yzurieta (1987, 1993), Nores & Yzurieta (1979), Nores *et al.* (1983), Olrog (1984), Parker *et al.* (1996), Ridgely & Tudor (1994), Smith & Vuilleumier (1971), Stattersfield & Capper (2000), Traylor (1977).

309. Rusty-backed Monjita

Xolmis rubetra

French: Pépoaza traquet **German**: Rotrücken-Nonnentyrann **Spanish**: Monjita Castaña

Taxonomy. *Taenioptera Rubetra* Burmeister, 1860, Sierra de Mendoza; [type from pampa S of Mendoza, near San Carlos and Totoral], Argentina.
Placed in *Myiotheretes* by early authors, and more recently sometimes included with seemingly dissimilar *X. salinarum* in *Neoxolmis*; possibly some affinities with *Agriornis*; further study needed. Monotypic.
Distribution. C Argentina, from Mendoza S to Chubut; winters N to N Argentina.



Descriptive notes. 18-19 cm. Male has rufescent crown, prominent long white supercilium, white head side with black streaks; back rufescent or rufous-brown, rump greyish-white; wings long, black, greater and median wing-coverts edged and tipped greyish-white, lesser coverts rufescent, tertials edged white; tail mostly black, outer web of three outer rectrices white; white below, neck side and breast with black streaks, flanks tinged rufous; iris dark; bill and legs black. Female is less rufescent and duller overall than male. Immature is dull buffy above, especially on head, buffish throat and breast. Voice. Little known; adults with fledglings give soft metallic "pik".
Habitat. Steppe and grassland with scattered low bushes (*Larrea*, *Condalia*, *Chuquiraga*); also lake margins. To 1000 m.
Food and Feeding. Insects. Often in pairs or small groups up to five individuals when breeding; flocks of up to 20 or 30 reported in austral winter. Often terrestrial, occasionally perches on wire or low bush; usually drops to the ground from a low perch. Runs swiftly, pauses with head erect; constantly opens and closes tail, and less frequently wings.
Breeding. Little known. Sept-Mar; fledglings in Dec in Chubut. During display male flies up and descends, with wings making metallic rattle. Nest an open cup made of twigs and grass, lined with feathers, internal diameter 12 cm, depth 5 cm, on ground at base of small bush. One nest held 2 chicks. No other information.
Movements. Resident in N. S populations migratory, spending winter (Apr-Aug) in N Argentina (N to Tucumán, Santiago del Estero, Santa Fe and Entre Ríos); one record from extreme W Uruguay (Paysandu).
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Uncommon at Valdés Peninsula, in Chubut. Habitat has been severely altered by overgrazing and deforestation, and native grassland and *Prosopis* forests virtually eliminated over large areas; as a result, the species has declined. Flocks of 20-30 individuals were common in Río Negro in middle of 19th century, whereas today it is fairly rare throughout much of its range. Was locally fairly common in Chubut, La Pampa, Neuquén and Río Negro in 1990s.
Bibliography. Bucher & Nores (1988), Canevari *et al.* (1991), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Joseph (1996), Lanyon (1986a), Luciano (1998), Meyer de Schauensee (1982), Narosky & Salvador (1998), Nores *et al.* (1983), de la Peña (1988, 1997), Ridgely & Tudor (1994), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Traylor (1977), Vuilleumier (1994), Wetmore (1926).

310. Black-and-white Monjita

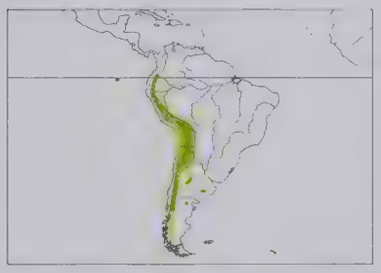
Xolmis dominicanus

French: Pépoaza dominicain **Spanish**: Monjita Dominicana
German: Schwarzschwanz-Nonnentyrann

Taxonomy. *T[yrannus] dominicanus* Vieillot, 1823, Río Plata, Paraguay.
Sometimes placed in a monotypic genus, *Heteroxolmis*, on basis of morphological and anatomical data. Monotypic.
Distribution. SW Paraguay, SE Brazil (Paraná, Rio Grande do Sul), Uruguay and NE Argentina (E Formosa and Misiones S to N Buenos Aires).

Descriptive notes. 20-20·5 cm. Male is mostly white, with pale greyish smudging on head and back; wings black, outer third of primaries white; tail rather long, black; iris dark; bill and legs black. Differs from *X. irupero* in larger size, less pure white colour, more black in wings, all-black tail. Female has crown and back brownish-grey, prominent white scapulars and rump. Juvenile has rusty back. Voice. Usually silent; soft, somewhat querulous "weeyrt" or "wurrt" call, especially when agitated.
Habitat. Marshes and bogs with sedge (*Cyperus* and *Eryngium*), open or burned areas, also landward side of coastal sand dunes; often forages in adjoining grassland. Generally below 500 m, occasionally to 1000 m.
Food and Feeding. Insects. Drops from low perch to ground for prey. Foraging birds often associated with Saffron-cowled Blackbird (*Agelaius flavus*) flocks, reasons unknown.
Breeding. Nests found Oct-Dec in SE Brazil (Rio Grande do Sul); late Sept to Dec in Argentina. Nest relatively bulky, substantial open cup of dry grasses, coarse stems and often some leaves, lined with finer grasses, a few feathers and/or wool, well hidden in low bush within small clump of marsh vegetation, or on clump of grass; five nests had mean length c. 16·4 cm, width 11·4 cm, height 7·5 cm, cup width 8·5 cm, cup depth 4·8 cm. Clutch 3-4 eggs; no information on incubation and fledging periods. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. Resident.
Status and Conservation. VULNERABLE. Rare to uncommon, and very local. Somewhat more numerous locally, e.g. in NE Rio Grande do Sul (Brazil) and N of Pinamar in E Buenos Aires (Argentina), but in general now extremely scarce. Since 1850, this species' population has undergone a catastrophic decline within its range of c. 120,000 km², this due mainly to drainage and agricultural conversion of natural grasslands, especially for livestock grazing; more recently, afforestation with non-native trees has begun to replace even more grasslands, especially rapidly in Entre Ríos and Corrientes (Argentina), where the species is still relatively common in recently burnt areas and has also been found in old paddyfields. Further threats are destruction of nests by fires and high levels of brood parasitism by Shiny Cowbird. Current stronghold possibly in SE Uruguay, with c. 1500-2200 individuals, mostly in Rocha; in Brazil common only near Arcos (Minas Gerais), in SE Santa Catarina and in NE & SE Rio Grande do Sul; in Argentina, decline especially marked in Buenos Aires, where previously common (and still is N of Pinamar), and most recent records from Corrientes and Entre Ríos. Occurs in Chaco, Mburucuyá and El Palmar National Parks, San Juan de Poriahú and Campos del Tuyú Private Reserves and Ribera Norte Municipal Reserve, all in Argentina. Aparados da Serra and São Joaquim National Parks, in Brazil, and Bañados del Este Biosphere Reserve and Laguna de Castillos, Potrerillo de Santa Teresa and Los Indios Reserves, all in Uruguay.
Bibliography. Belton (1985), Canevari *et al.* (1991), Chebez (1994), Collar & Andrew (1988), Collar *et al.* (1994), Contreras (1995b), Cory & Hellmayr (1927), Di Giacomo & Krapovickas (2001), Fontana (1997), Fontana & Voss (1995), Fraga (2003), Lanyon (1986a), Meyer de Schauensee (1982), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Navas & Bó (1993a), Orians (1978), Pearman & Abadie (1995), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Suertegaray (1997), Tobias *et al.* (1993), Vuilleumier (1994).



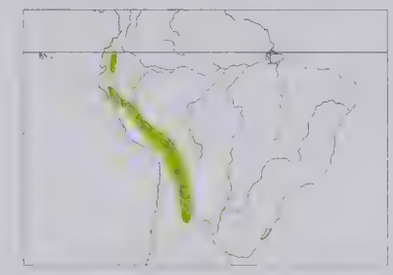
Genus *AGRIORNIS* Gould, 1839

311. Black-billed Shrike-tyrant

Agriornis montanus

French: Gaucho à bec noir **German**: Schwarzschnabel-Hakentyrann **Spanish**: Gaucho Serrano
Other common names: Black-billed Ground-tyrant

Taxonomy. *P[epoaza] Montana* d'Orbigny and Lafresnaye, 1837, Chuquisaca, Bolivia.
Race *intermedius* is likely to be a clinal variant of *insolens*, nominate and *maritimus*, as it is phenotypically and geographically intermediate between these three races and does not exhibit a constant set of diagnosable features. Described race *leucurus* (from Patagonia) merged with *maritimus*, from which it appears indistinguishable. Five subspecies currently recognized.
Subspecies and Distribution.
A. m. solitarius P. L. Sclater, 1859 - Andes of S Colombia and Ecuador.
A. m. insolens P. L. Sclater & Salvin, 1869 - temperate zone of Peru.
A. m. intermedius Hellmayr, 1927 - W Bolivia (La Paz, Oruro) and N Chile (Tarapacá).
A. m. montanus (d'Orbigny & Lafresnaye, 1837) - E & S Bolivia and NW Argentina (Jujuy S to Tucumán and La Rioja).
A. m. maritimus (d'Orbigny & Lafresnaye, 1837) - Andes of C & S Chile (Tarapacá to Magallanes) and WC & SW Argentina (W Mendoza to W Santa Cruz); also C Argentina, in hills of Córdoba, S Buenos Aires and Somuncará Plateau.



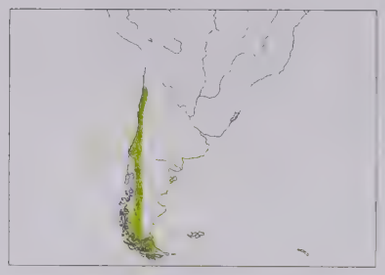
Descriptive notes. 23-24 cm. Nominate race has indistinct whitish supraloral stripe, narrow and broken buffish-white supercilium; cheek white, streaked dark brown; mainly dark greyish-brown above; inner remiges edged and tipped whitish; central pair of tail feathers blackish, remainder white (conspicuous in flight) with dark inner webs basally; white throat narrowly streaked blackish, breast and flanks ashy brown, whitish tinge on mid-belly, whitish lower belly and vent; underwing-coverts cinnamon-buff to buffy white; iris yellowish to ivory; bill hooked, black; legs blackish. Sexes alike. Juvenile is like adult, but base of lower mandible pale to yellowish. Race *solitarius* is darker than nominate, outer tail all white; *insolens* is somewhat paler than previous, four outer pairs of rectrices white, sometimes narrow dusky margin along inner web of fourth (and, rarely, third) pair; *maritimus* has whitish tips of central tail feathers, more black at base of tail feathers, S populations ("*leucurus*") also darker on underparts than nominate; *intermedius* is similar to previous, but lateral rectrices with much less black at base, two outermost pairs sometimes wholly white. VOICE. Sometimes fairly vocal, especially at dawn, though often silent: call a loud, whistled "wheee, wheeeu", rising and then falling, or just "wheeeu"; also a loud whistled "pyuk". Male clicks bill during territorial disputes, attenuated outer primaries produce low-pitched, almost inaudible whirring sound during aerial display.
Habitat. Mainly high open places in Andes. Wide-ranging in open grassy and agricultural areas with scattered bushes and trees in upper temperate zone and *páramo*, edge of *Polylepis* forest, *puna* grassland with fence posts or scattered rocks and boulders, rocky slopes and cliffs, villages, ploughed fields; also around buildings. May roost in caves. Mainly 3000-4000 m, locally down to 2000 m and up to 4500 m; as low as 1830 m in Peru, and, rarely, breeds down to sea-level in Chile (Tarapacá S to Coquimbo).
Food and Feeding. Large insects, small mammals, lizards, frogs, eggs or nestlings of other birds, and seeds. Perches conspicuously on rocky outcrops or bushtops, taking most prey from the ground or by hawking; sometimes approachable, but often flies long distances when flushed. Glides slowly from rock to rock when hunting, sometimes hovering briefly, and drops down on to any prey spotted. Runs well, and sometimes pumps tail up and down.
Breeding. Nests found in Dec-Jan in Argentina; eggs in Nov in N & C Chile; nestlings in Oct in S Peru (Arequipa); juveniles in Dec-Jan and Aug and food-carrying adults in mid-Aug in Ecuador; juveniles in Dec (Junín, Amazonas), Mar (Cuzco) and May (W La Libertad) in Peru, and Feb and Apr in Bolivia (Cochabamba). Male performs aerial display. Nest a large loosely made open cup of dry sticks and grass, lined with wool, one with diameter 15 cm, height 9 cm and depth 4 cm; placed on ground or vegetation in *páramo*, or in rock crevice, low in bush near stream, under tile roof, or in mud wall of house. Clutch 2-3 eggs; no information on incubation and fledging periods.
Movements. Mainly resident, but populations of far S move N for winter.
Status and Conservation. Not globally threatened. Uncommon to fairly common; most numerous and widespread member of genus in Andes. Occurs in e.g. Machu Picchu Historical Sanctuary and Huascarán and Sajama National Parks, in Peru, and Lauca National Park, in Chile. Densities not very high, as it appears to have large territories.
Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hilty & Brown (1986), Hoy (1976), Jaramillo (2003), Johnson, A.W. (1965, 1967), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rocha & Peñaranda (1995), Rocha & Quiroga (1996), Salaman (1994), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Vuilleumier (1994), Wetmore (1926), Zimmer (1930).

312. White-tailed Shrike-tyrant

Agriornis andicola

French: Gaucho à queue blanche **Spanish**: Gaucho Andino
German: Weißschwanz-Hakentyrann

Taxonomy. *Agriornis andicola* P. L. Sclater, 1860, Panza, Ecuador.
Species formerly referred to sometimes as *A. albicauda*, as current name was considered, erroneously, to be preoccupied. Races poorly differentiated. Two subspecies recognized.
Subspecies and Distribution.
A. a. andicola P. L. Sclater, 1860 - Ecuador.
A. a. albicauda (R. A. Philippi [Krumwiede] & Landbeck, 1863) - Peru, W Bolivia, N Chile and NW Argentina.



Descriptive notes. 25-28 cm. Has narrow buff supercilium, streaked head side; dark grey-brown above, some pale margins on wings; central tail feathers like back, remainder white with small dark markings at tips; throat white, streaked blackish; upper breast and sides grey-brown, lower breast, belly and vent whitish, irregularly tinged buff; underwing-coverts cinnamon-buff; iris dark; bill large, heavy, powerfully hooked, upper mandible dark, lower mandible pale horn-coloured to yellowish; legs blackish. Distinguished from similar *A. montanus* by larger size and bulkier shape, dark iris, heavier bill with pale yellowish lower mandible, markedly sharper and blacker throat streaking. Sexes similar. Race *albicauda* is very similar to nominate. VOICE. Call a surprising and loud, melodic "teeu, tcheeu-tcheeu-tcheeuw!", with many variations. Adult male's attenuated two outer primaries produce low-pitched whirring sound during aerial display.
Habitat. *Páramo*, *puna* and montane scrub and areas having sparse and xeric vegetation of low shrubs, with *Puya* shrubs, scattered rocks or boulders for perching; also around buildings and walls. Also found in open farmland with eucalypt (*Eucalyptus*) trees locally in Ecuador (W of Saragura). Above 2450 m in Ecuador (nominate race); 3660-4500 m from Peru and Bolivia S (*albicauda*).
Food and Feeding. Large insects, small mammals, lizards, frogs, eggs or nestlings of other birds. Perches conspicuously on rocky outcrops or on bushes, taking most prey from the ground, or by hawking in the air. Sometimes occurs together with *A. montanus*.
Breeding. Birds with enlarged gonads in Jun in NW Ecuador. Male during aerial display circles silently, alternately rising to partial stall and dropping forward on closed wings. No other information.
Movements. Resident.
Status and Conservation. VULNERABLE. Very rare and local. Was apparently once much more numerous, but has declined in recent decades. Total population of a few thousands becoming increasingly fragmented in its relatively large range. Reasons for scarcity and decline somewhat unclear; this species could be especially sensitive to habitat modification such as clearing of bushy vegetation, as stands of large *Puya raimondii* (required for nesting) are actively destroyed by sheep-farmers, or could be unusually prone to persecution (e.g. hunting with slings). Has been recorded (sometimes not for several decades) in Podocarpus National Park, in Ecuador, Salinas y Aguada Blanca National Reserve and Huascarán National Park, in Peru, and Lauca National Park, in Chile. In Argentina, a few individuals found recently in Sierra de Aconquija above Tafi del Valle (Tucumán), in the "Campo de los Alisos" conservation area. Scattered records from unprotected sites throughout its range, but everywhere it appears rare and outnumbered by *A. montanus*, which may outcompete it in some unknown manner. Appears locally extinct in N Ecuador, although described as common around Quito in middle of 19th century (but perhaps confused with *A. montanus*). Further surveys at additional localities are needed.
Bibliography. Araya & Chester (1993), Begazo *et al.* (2001), Canevari *et al.* (1991), Chebez (1994), Clements & Shany (2001), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Herzog *et al.* (1999), Howell & Webb (1995b), Jaramillo (2003), Johnson (1967), Krabbe *et al.* (1996), Marín (2004), Pacheco (2002a), de la Peña (1988), Pulido (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Vuilleumier (1994), Wege & Long (1995), Zimmer (1930, 1937a).

313. Great Shrike-tyrant

Agriornis lividus

French: Grand Gaucho **German**: Schwarzschwanz-Hakentyrann **Spanish**: Gaucho Grande

Taxonomy. *Tamnophilus* [sic] *lividus* Kittlitz, 1835, mountains of Valparaíso, Chile.
Two subspecies recognized.
Subspecies and Distribution.
A. l. lividus (Kittlitz, 1835) - coast and mountains of Chile (Atacama S to Valdivia).
A. l. fortis Berlepsch, 1907 - S Chile (Aisén and Magallanes) and S Argentina (L Nahuel Huapi, in S Chubut, S to Tierra del Fuego).
Descriptive notes. 26-28 cm. The largest flycatcher. Has dark head, ear-coverts tinged cinnamon, some whitish mottling on lores; mostly dull greyish-brown above; wings duskier, wing feathers obscurely edged pale brown; tail black, narrow tip and outer web of outer feather buffy white; throat white, sharply streaked black; underparts slightly paler greyish-brown, lower belly and,

especially, crissum washed cinnamon or cinnamon-buff; iris dark; bill heavy, strongly hooked, upper mandible black, lower mandible pale horn and becoming darker at tip; legs blackish. Sexes alike. Juvenile is browner and indistinctly streaked dusky on head, back and upper breast, has much less streaking on throat, entire belly cinnamon-buff. Race *fortis* is somewhat larger than nominate, and overall very slightly brighter. Voice. Usually silent; call "t-eek" or "t-eek-ek". Adult male's attenuated two outer primaries produce low-pitched, almost inaudible whirring sound during aerial display.

Habitat. Semi-open shrubby and agricultural regions; avoids both very xeric and very wet habitats, as well as wooded or heavily populated areas. Found in sub-arid countryside with large patches of bushes, thick scrub (such as *Chiliotrichium amelloideum*), cacti and bromeliads; open flats, pastures dotted with bushes on surrounding slopes, trees in transitional *Nothofagus* forest. Sea-level to 1800 m, mostly below 1500 m.

Food and Feeding. Large insects, small mammals, lizards, frogs, eggs or nestlings of other birds; rarely small birds, including *Anairetes parulus*. Occurs in highly dispersed pairs. Perches conspicuously on rocky outcrops or in bushtops, taking most prey from the ground, or by hawking in air.

Breeding. Oct (coastal) and Nov (interior) in Chile. Male has aerial display. Bulky cup-shaped stick nest, lined with grass and wool, placed in bush or cactus. Clutch 2-4 eggs, usually 3. No other information.

Movements. Resident.

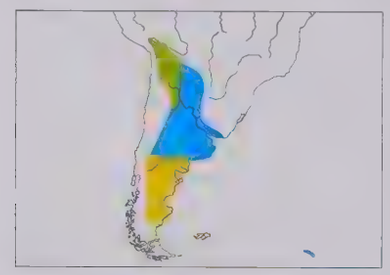
Status and Conservation. Not globally threatened. Uncommon, becoming rare in S part of range. Most common in C Chile (from Aconcagua S to Bío Bío) and in SC Patagonia (Chubut and Aisén). Found in many national parks within its range.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Clark (1986), Cofré & Vilina (1999), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Cracraft (1985), Fjeldså & Krabbe (1990), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Núñez (1995), de la Peña (1988), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1994).

314. Grey-bellied Shrike-tyrant

Agriornis micropterus

French: Gaucho argentin **German**: Weißbrauen-Hakentyrann **Spanish**: Gaucho Gris



Taxonomy. *Agriornis micropterus* Gould, 1839, Port Desire, Patagonia, Argentina.

Two subspecies recognized.

Subspecies and Distribution.

A. m. andecola (d'Orbigny, 1840) - temperate zone of S Peru, Bolivia (La Paz, Cochabamba, Oruro, Potosí), N Chile (Tarapacá) and NW Argentina (Jujuy, Salta, Catamarca, Tucumán).

A. m. micropterus Gould, 1839 - breeds Andes of C & S Argentina (Mendoza, La Pampa and S Buenos Aires S to Santa Cruz); S breeders migrate N.

Descriptive notes. 23-24·5 cm. Male nominate race has crown grey-brown, supercilium whitish, ear-coverts tinged rufous; generally grey-brown above, wing-coverts pale greyish, flight-feathers edged whitish; tail black, slender white edge of outer feathers; throat and throat side white, heavily streaked black; underparts pale brown, belly pale grey-brown to whitish, flanks washed buffy; iris dark; bill strong, straight, hook-tipped, upper mandible dark brown, lower mandible orange; legs dusky. Female has throat streaked dark brown. Juvenile is browner, underparts pale cinnamon-brown, throat markings more or less absent. Race *andecola* is larger than nominate, slightly darker, vent tinged tawny. Voice. Usually silent; male pursuing another gives high-pitched petulant calls; also high-pitched whistle in breeding season. Adult male's two attenuated outer primaries produce low-pitched, almost inaudible whirring sound during aerial display.

Habitat. Open shrubby steppes (with *Baccharis*), hillsides, and *puna* grassland with some shrubbery and boulders; also in open agricultural areas in austral winter. Sea-level to 5000 m; mostly 2000-4000 m in N part of range, regularly to sea-level in S.

Food and Feeding. Large insects, small mammals, lizards, frogs, and eggs or nestlings of other birds. Perches conspicuously on rocks or in bushtops; takes most prey from the ground or by hawking in air; often runs along ground while picking up insects, occasionally flying to catch insects on the wing. Often flies long distances low over ground.

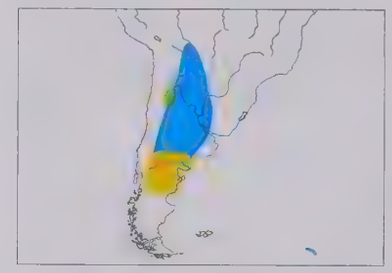
Breeding. Eggs in Jan in Chile (Tarapacá); nests found in Sept and Oct and eggs and begging fledgling in Dec in Argentina. Male has aerial display. Nest bulky, cup-shaped, mostly of sticks and large twigs, one with external diameter 20 cm, height 9·5 cm, internal diameter 9·5 cm, depth 6·5 cm, corresponding dimensions of another 11 cm, 9 cm, 8 cm and 7 cm; placed 1 m or more above ground in bush, in one case *Condalia microphylla*. Clutch 3-4 eggs; no information on incubation and fledging periods. Parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded once in Argentina.

Movements. Resident in N (*andecola*). S population (nominate) migrates N in austral winter (at least Jun-Oct), spreading over much of Argentina and occurring N at least casually to Bolivia (Cochabamba); leaves breeding grounds in Feb, spends non-breeding period from S Bolivia, Paraguay (rare but regular) and Uruguay (very rare, no recent records) S to Córdoba and N Buenos Aires.

Status and Conservation. Not globally threatened. Generally uncommon, locally fairly common. Fairly common in N Chile (Collacagua Valley and around San Pedro de Atacama), but apparently scarce elsewhere.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chesser (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Cracraft (1985), Di Giacomo (2004), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Harris (1998), Hayes (1995), Howell & Webb (1995b), Joseph (1996), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1988), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1994), Zapata & Martínez (1972), Zimmer (1937a).

315. Lesser Shrike-tyrant



Agriornis murinus

French: Gaucho souris **German**: Kleinhakentyrann **Spanish**: Gaucho Chico
Other common names: Least/Mouse-brown Shrike-tyrant

Taxonomy. *P[epoaza] Murina* d'Orbigny and Lafresnaye, 1837, Río Negro, Argentina.

Formerly placed in *Xolmis* by some authors on grounds of shared behavioural traits and morphological similarities, but nowadays normally included in present genus, which it closely resembles in plumage colour and pattern; this species appears to be somewhat intermediate between the two genera, thus supporting their possible merging; further study required. Monotypic.

Distribution. Breeds in NW & SC Argentina (Catamarca, Tucumán and La Rioja, and from Neuquén, Río Negro and SW Buenos Aires S to Santa Cruz; may also breed in intervening zone); winters N as far as C Bolivia.

Descriptive notes. 16-18·5 cm. Has crown grey-brown, supercilium and eyering whitish, lores mixed blackish and white; upperparts grey-brown, wings dusky with whitish tips of wing-coverts, whitish edge of inner primaries; tail dusky, outer web of outermost feather pair greyish (appears black in flight); throat white with contrasting black streaks, becoming very pale greyish-brown on breast and creamy whitish on belly, often tinged buff on flanks; iris dark; bill rather slender, slightly hooked, black; legs blackish. Sexes similar, but female has throat streaking somewhat browner Voice. Usually silent; during pursuits gives sharp squeaky notes; occasional high-pitched whistle-like call. Adult male's attenuated outermost primaries produce low-pitched, almost inaudible whirring sound during aerial display.

Habitat. Open plains with dry scrub and scattered trees during breeding season; also agricultural areas in non-breeding period. Sea-level to 2500 m; at highest altitudes usually in austral winter in Bolivia.

Food and Feeding. Large insects, small mammals, lizards, frogs, and eggs or nestlings of other birds. Generally forages alone. Usually perches on top of shrubs, dropping to the ground and occasionally running rapidly to take prey; sometimes hawks in short flights. When running (sometimes for considerable distances), often stops and then cocks head to one side to inspect surroundings.

Breeding. One nest found in Nov, a cup made of stems, lined with grass and feathers, external dimensions 12 × 13·5 cm, height 7 cm, internal diameter 7·5 cm, depth 4·5 cm; placed 40 cm above ground in *Heterostachys* bush; contained 3 eggs. No other information.

Movements. Migratory. After breeding migrates N; spends austral winter (May-Sept) in much of rest of Argentina (except far NE) and N to W Paraguay and C & S Bolivia (N to Cochabamba and W Santa Cruz).

Status and Conservation. Not globally threatened. Uncommon to fairly common. No obvious potential threats. Survey work required in order to establish precise limits of breeding range.

Bibliography. Andors & Vuilleumier (1996), Canevari *et al.* (1991), Chesser (1997), Couve & Vidal-Ojeda (2003), Cracraft (1985), Di Giacomo (2004), Fjeldså & Krabbe (1990), Harris (1998), Hayes (1995), Joseph (1996), Meyer de Schauensee (1966, 1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Wetmore (1926), Zapata & Martínez (1972).

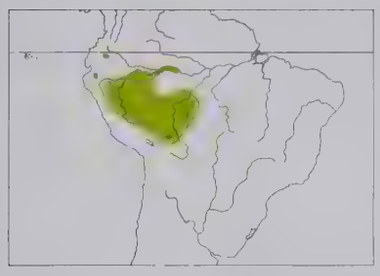
PLATE 39 ➤

PLATE 39

inches 4

cm 10

Genus *MUSCISAXICOLA*



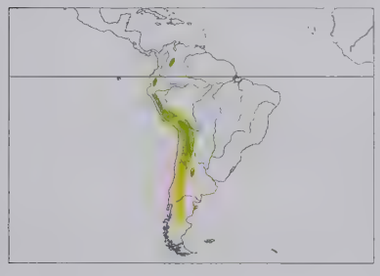
d'Orbigny & Lafresnaye, 1837

316. Little Ground-tyrant

Muscisaxicola fluviatilis

French: Dormilon fluviatile **German**: Tiefland-Grundtyrann **Spanish**: Dormilona Enana

Taxonomy. *Muscisaxicola fluviatilis* P. L. Sclater and Salvin, 1866, lower River Ucayali, Peru.
Usually considered closely allied with *M. maculirostris*; recent phylogenetic work, however, suggests that this species may be more closely related to other taxa (e.g. *Muscigralla*) than it is to current congeners. Monotypic.
Distribution. Extreme SE Colombia, E Ecuador and E Peru (N bank of R Marañón S to R Inambari) to W Brazil (E to middle R Amazon and upper R Madeira region) and NW & C Bolivia (to Cochabamba).



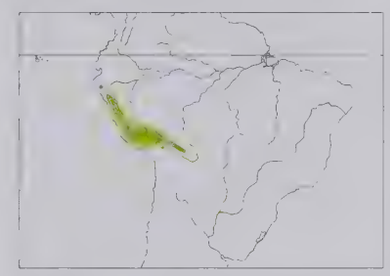
Descriptive notes. 13-14 cm. Has pale buffy supraloral line and eyering; above, greyish and sandy brown, wings dusky, inner remiges very narrowly edged pale greyish-cinnamon or rufescent, greater wing-coverts with narrow buffy tips (sometimes showing vague rufescent wingbars); tail black, outer web of outer feathers white; throat and breast buffy white, belly lighter; iris dark brown; bill mainly black, base of lower mandible pale fleshy yellow or orange-yellow; legs blackish. Distinguished from *M. maculirostris* by proportionally shorter tail, reduced white supraloral, contrasting white belly. Sexes alike. Voice. Usually quiet; call a single high-pitched "peeeép" with rising inflection.
Habitat. Open or sparsely vegetated sandbars and river islands; sometimes in adjacent open grassy areas. The only ground-tyrant in lowlands of Amazonia. Mostly below 800 m; rarely to 1400 m in Ecuador, 1900 m in Peru; very occasionally perhaps higher, to 3200-3800 m in Bolivia (although these specimens appear to be anomalous).
Food and Feeding. Insects. Usually found singly or in pairs, running in open, though rather inconspicuous (dorsal coloration similar to that of usual sandy habitat). Sometimes associated with migrant shorebirds. Mainly terrestrial, making short runs and hops after prey, stopping suddenly and standing erect; less frequently, sallies from the ground or a rock.
Breeding. Aug-Oct in SE Peru. Nest is inconspicuous cup of weeds and twigs on ground amongst emerging *Tessaria* on large sandy beaches. Clutch 2 eggs.
Movements. Resident. Some possible movement; e.g. records at highland localities, e.g. in Colombia, Ecuador and Bolivia (L Titicaca, 3800 m), may involve vagrants.
Status and Conservation. Not globally threatened. Uncommon and local. Occurs in e.g. Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, Pilón Lajas Biosphere Reserve and Madidi National Park, in Bolivia, and Mamirauá Reserve (Amazonas), in Brazil.
Bibliography. Allen (1995), Chapman (1921), Chesser (2000), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick (1980c, 1981, 1985a), Fjeldså & Krabbe (1990), Hennessey, Herzog, Kessler & Robinson (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Pacheco (1995), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Terborgh *et al.* (1984), Zimmer (1930).

317. Spot-billed Ground-tyrant

Muscisaxicola maculirostris

French: Dormilon à bec maculé **Spanish**: Dormilona Chica
German: Schnabelfleck-Grundtyrann

Taxonomy. *M[uscisaxicola] maculirostris* d'Orbigny and Lafresnaye, 1837, La Paz, Bolivia.
Usually considered closely allied with *M. fluviatilis*; recent phylogenetic work, however, does not suggest so close a relationship. Three subspecies recognized.
Subspecies and Distribution.
M. m. niceforoi J. T. Zimmer, 1947 - N part of E Andes of Colombia.
M. m. rufescens Berlepsch & Stolzmann, 1896 - Ecuador.
M. m. maculirostris d'Orbigny & Lafresnaye, 1837 - breeds Peru, Bolivia, Chile and W Argentina (Jujuy S to Santa Cruz); S populations migrate N.



Descriptive notes. 14-15 cm. Smallest highland ground-tyrant. Nominate race has short buffish-white supercilium, dusky line through eye; smoky grey with brownish tinge above, wings duskier with cinnamon-buff edging; tail black, outer web of outer feather pair whitish; throat dusky whitish, underparts uniform buffy white; iris dark brown; bill black, base of lower mandible yellowish to orange-yellow ("spot-billed"); legs black. Differs from *M. fluviatilis* in proportionally longer tail, stronger supercilium, more uniform underparts. Sexes alike. Juvenile has wings edged cinnamon. Race *niceforoi* is much like nominate, but with more cinnamon-buff underparts; *rufescens* is more rufous-brown, underside cinnamon-buff, underwing-coverts tawny-buff. Voice. In aerial display "t-t-tk-tk" and "wheeoo", repeated up to 15 times; also utters short "tek".
Habitat. Xeric barren areas with sparse bushy vegetation, preferring steep rocky slopes, banks or walls; occasionally along shores of high lagoons but, unlike congeners, shows no affinity for water. At 1000-4000 m, occasionally wandering down to sea-level.
Food and Feeding. Insects. Usually singly or in pairs; less often in small and loose groups during non-breeding period; less conspicuous than other ground-tyrants. Mainly terrestrial, making short runs and hops after prey, stopping suddenly and standing erect; less frequently, sallies from the ground or a rock. Regularly perches on bushtops, walls and half-way up banks.
Breeding. Generally Oct-Mar; Jun-Jul in Ecuador and Colombia, eggs in Oct-Nov in Chile, and nests in Dec-Jan and fledgling in Feb in Argentina. Occasionally loose "colonies" in particularly favourable habitat. In aerial display, with calling, flutters up, stalls and then swoops to ground. Nest an open cup, made from dry grass, lined with small feathers, exposed or partially concealed on ground, especially near bush, grass tuft or rock. Clutch 2-4 eggs; no information on incubation and fledging periods.
Movements. Mostly resident; at least a partial migrant in S portion of range, most birds moving N after breeding.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Apparently less abundant in N & S than in C parts of range; isolated N race *niceforoi* is included on Colombian red list as "endangered". Occurs in e.g. Machu Picchu Historical Sanctuary, in Peru, and Eduardo Avaroa National Park, in Bolivia, and most national parks in S Andes.
Bibliography. Araya & Chester (1993), Cadena & Renjifo (2002), Canevari *et al.* (1991), Chapman (1921), Chesser (1997, 2000), Clements & Shany (2001), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Hennessey, Herzog, Kessler & Robinson (2003), Hilty & Brown (1986), Jaramillo (2003), Johnson, A.W. (1965, 1967), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1988), Quiroga *et al.* (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rocha & Quiroga (1996, 1998), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Varty *et al.* (1986), Walker (2001), Wetmore (1926), Zimmer (1930).

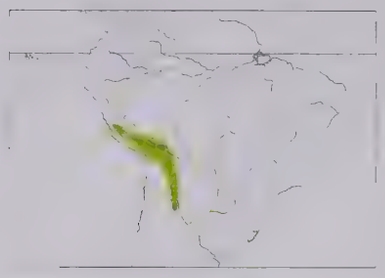
318. Taczanowski's Ground-tyrant

Muscisaxicola griseus

French: Dormilon gris **German**: Graubrust-Grundtyrann **Spanish**: Dormilona de Taczanowski

Taxonomy. *Muscisaxicola grisea* Taczanowski, 1884, Maraynioc, Peru.
Formerly considered conspecific with *M. alpinus*; recent molecular work supports treatment as distinct species. Monotypic.
Distribution. Peru and NW & C Bolivia (La Paz, Cochabamba).

Descriptive notes. 18-19 cm. Has long white supercilium extending beyond eye, small white area below eye, dusky lores; crown brownish-grey, slightly streaked appearance; upperparts pure smoky grey, wings duskier, some pale edging on wing-coverts; tail blackish, outer feather narrowly edged white; throat white, breast grey, abdomen white with buff tinge; iris dark; bill and legs black. Differs from *M. alpinus* in lacking brownish wash above and faint sepia on crown. Sexes alike. Voice. Unknown.
Habitat. Open *páramo* or *puna* grassland; level or gently sloping grassy soil, sometimes on dry, sparsely vegetated ground. At 2700-4800 m.
Food and Feeding. Insects. Mainly terrestrial; forages with short runs and hops, stopping suddenly and standing erect (though less erect than congeners), and occasionally taking a slightly elevated perch; less frequently, sallies from the ground or a rock. Swift and direct flight, sometimes flicking tail and quivering or drooping wings upon landing. Regularly in loose flocks in non-breeding season, occasionally with other ground-tyrants or other *puna*-zone birds.
Breeding. Juveniles in Dec in Peru (Puno, Cuzco) and Jan in Bolivia (La Paz). No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally fairly common in limited range. Rather poorly known species.
Bibliography. Chapman (1921), Chesser (1994, 2000), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Koepcke (1970), Ridgely & Tudor (1994), Walker (2001), Zimmer (1930).



319. Puna Ground-tyrant

Muscisaxicola juninensis

French: Dormilon de Junin **German**: Braunscheitel-Grundtyrann **Spanish**: Dormilona Puneña

Taxonomy. *Muscisaxicola juninensis* Taczanowski, 1884, Junín, Peru.
Has in the past been considered closely related to, and perhaps conspecific with, *M. albilora*. Monotypic.
Distribution. C & S Peru (Junín S to Tacna and Puno), N Chile (Tarapacá), SW Bolivia (La Paz S to Potosí) and NW Argentina (S to W Tucumán).
Descriptive notes. 16·5 cm. Has white supraloral, faint pale supercilium and broken eyering; most of crown tinged dull cinnamon (but lacks distinct coronal patch); upperparts pale brownish-grey, lower rump black, wings dusky grey; tail black, outer web of outer feathers edged white; pale grey below, throat and belly whitish; iris dark; bill and legs black. Distinguished from *M. albilora* by browner (less grey) appearance, less pronounced supercilium, smaller bill. Sexes alike. Juvenile has wing-coverts edged pale cinnamon, underparts buffy. Voice. Unknown.
Habitat. Hillsides and *puna* grassland and grassy steppes, most often close to rock outcroppings, boulders or cliffs; bogs with matted vegetation and slightly drier grass, stones at edge of bogs and

On following pages: 320. Cinereous Ground-tyrant (*Muscisaxicola cinereus*); 321. White-fronted Ground-tyrant (*Muscisaxicola albifrons*); 322. Ochre-naped Ground-tyrant (*Muscisaxicola flavinucha*); 323. Rufous-naped Ground-tyrant (*Muscisaxicola rufivertex*); 324. Dark-faced Ground-tyrant (*Muscisaxicola maclovianus*); 325. White-browed Ground-tyrant (*Muscisaxicola albilora*); 326. Plain-capped Ground-tyrant (*Muscisaxicola alpinus*); 327. Cinnamon-bellied Ground-tyrant (*Muscisaxicola capistratus*); 328. Black-fronted Ground-tyrant (*Muscisaxicola frontalis*); 329. Streamer-tailed Tyrant (*Gubernetes yetapa*); 330. Shear-tailed Grey Tyrant (*Muscipipra vetula*).

lakes, or marshes. Also slopes with uneven soil (ploughed). Recorded at 3200-5000 m, but usually above 4200 m.

Food and Feeding. Diet consists of insects. Mainly terrestrial, making short runs and hops, then stopping suddenly and standing erect; less frequently, sallies from the ground or a rock. Often forms loose flocks in non-breeding season.

Breeding. Little known. Eggs in Oct in Chile, and juvenile in Jan in Bolivia (Potosí). Nest apparently placed in crevice between rocks. No other information.

Movements. Resident; some altitudinal displacement during harsh weather.

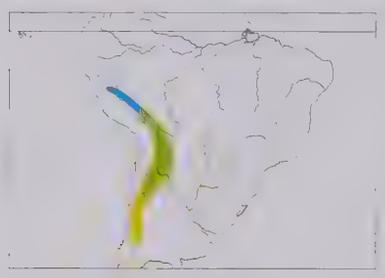
Status and Conservation. Not globally threatened. Locally fairly common to common. Occurs in e.g. Machu Picchu Historical Sanctuary, in Peru, Sajama and Eduardo Avaroa National Parks, in Bolivia, Lauca National Park, in Chile and Los Cardones National Park, in Argentina.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Johnson (1967), Koepcke (1970), Marín (2004), Mazar Barnett, Clark *et al.* (1998), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Tudor (1994), Rocha & Quiroga (1996, 1998), Stotz *et al.* (1996), Walker (2001).

320. Cinereous Ground-tyrant

Muscisaxicola cinereus

French: Dormilon cendré **German**: Graubraun-Grundtyrann **Spanish**: Dormilona Cenicienta



Taxonomy. *Muscisaxicola cinerea* R. A. Philippi [Krumwiede] & Landbeck, 1864, Arañas, Valle Largo, Las Chacarillas, Cordilleras de Santiago, Chile.

Formerly considered conspecific with *M. alpinus* by some authors. Two subspecies currently recognized.

Subspecies and Distribution.

M. c. cinereus R. A. Philippi [Krumwiede] & Landbeck, 1864 - breeds Peru (S Puno), Bolivia, N Chile (Coquimbo S to Talca) and W Argentina (Mendoza); S populations migrate N.

M. c. argentina Hellmayr, 1932 - breeds NW Argentina (Jujuy S to Catamarca); S populations migrate N.

Descriptive notes. 16·5 cm. Relatively plain-headed. Has narrow white supercilium extending to eye, dusky lores; greyish-brown above, wings duskier, some pale edging on wing-coverts; tail blackish, outer feather narrowly edged white; greyish-white below, whiter on belly; iris dark brown; bill and legs black. Distinguished from *M. alpinus* by smaller size, paler and greyer head and upperparts, paler breast hardly contrasting with throat, narrower and shorter supercilium; from *M. griseus* by smaller size, narrow and short white supraloral extending back only to over eye. Sexes alike. Race *argentina* is slightly larger than nominate, otherwise very similar. Voice. Unknown.

Habitat. Montane scrub, open *puna* grassland, rocky pastures near streams and lakes; near bogs and lakesides in austral winter. Mostly 2500-5000 m.

Food and Feeding. Insects. Mainly terrestrial, making short runs and hops, stopping suddenly and standing erect; less frequently, sallies from the ground or a rock.

Breeding. Sept-Mar; nests found in Nov in Chile and Argentina, also eggs in Oct in Chile, and fledglings in Dec in Argentina Jan in S Peru. Nest an open grass cup, lined with feathers and horsehair, placed in crevice between rocks; one in Argentina with internal diameter 6 cm, depth 4 cm. Clutch 2 eggs. No other information.

Movements. Some migration N during austral winter, birds reaching C Peru (Lima and Junín).

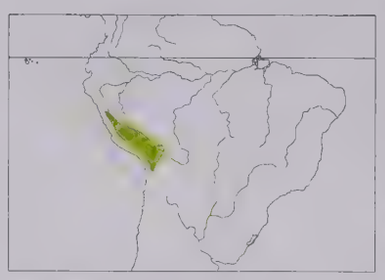
Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in e.g. Machu Picchu Historical Sanctuary, in Peru, and Sajama and Eduardo Avaroa National Parks, in Bolivia.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chesser (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hennessey, Herzog & Sagot (2003), Jaramillo (2003), Johnson (1967), Joseph (1996), Landbeck (1877), Marín (2004), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Quiroga *et al.* (1998), Ridgely & Tudor (1994), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Vuilleumier (1994), Walker (2001).

321. White-fronted Ground-tyrant

Muscisaxicola albifrons

French: Dormilon à front blanc **German**: Weißstirn-Grundtyrann **Spanish**: Dormilona Gigante



Taxonomy. *Pt[yonura] albifrons* Tschudi, 1844, Junín, Peru.

Monotypic.

Distribution. C & S Peru (S from Lima and Junín), W Bolivia (La Paz) and extreme N Chile (Cordillera de Arica, in Tarapacá).

Descriptive notes. 20-21·5 cm. Largest *Muscisaxicola*, with long wings (primaries extend nearly to tail tip). Has conspicuous white forehead merging on to supercilium, brownish crown, dull brown hindcrown; upperparts smoky grey; secondaries and wing-coverts edged silvery grey; tail blackish, outer 2-3 feathers pale-edged, outer web of outermost wholly pale from below; pale smoky grey below, turning whitish on central belly, vent white, underparts with faint pale streaks; iris dark brown; bill and legs black. Sexes alike. Juvenile undescribed. Distinguished from *M. flavinucha* by slightly larger size, white patch formed by feather edges on wing-coverts and base of remiges (evident in flight and at rest), no yellow occipital patch, greyer belly. Voice. Unknown.

Habitat. High *puna* grassland and barren rocky hillsides with boulders and cliff faces but little or no shrubbery; often forages on bogs dominated by flat-topped cushion-plants and matted grass, also adjacent grassy slopes. At 4000-5600 m.

Food and Feeding. Insects. Usually solitary, even in non-breeding season. Forages mostly on the ground, pursuing prey by running or in short and swift low flights; posture very upright.

Breeding. Eggs in Nov and Jan in Chile. Nest an open cup, placed on slope with sparse low shrubs and bunchgrass. No other information available.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally considered uncommon to fairly common. Occurs in several protected areas, including Machu Picchu Historical Sanctuary, in Peru, and Lauca National Park, in Chile. Restricted to higher elevations; can be found, for instance, at La Cumbre pass, N of La Paz, in Bolivia.

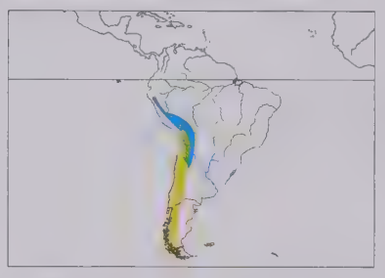
Bibliography. Araya & Chester (1993), Chapman (1921), Chesser (1996), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Jaramillo (2003), Johnson (1967), Koepcke (1970), Marín (2004), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Tschudi (1844-1846), Walker (2001).

322. Ochre-naped Ground-tyrant

Muscisaxicola flavinucha

French: Dormilon à nuque jaune **German**: Gelbnacken-Grundtyrann **Spanish**: Dormilona Fraile

Taxonomy. *M[uscisaxicola] flavinucha* Lafresnaye, 1855, Chile.



Two subspecies recognized.

Subspecies and Distribution.

M. f. flavinucha Lafresnaye, 1855 - breeds N & C Chile (Antofagasta S to Colchagua) and W Argentina (Mendoza S to Santa Cruz).

M. f. brevirostris Olrog, 1949 - breeds S Chile and S Argentina S to Tierra del Fuego.

Species winters N to N Peru and W Bolivia.

Descriptive notes. 18-5-20 cm. Large and long-winged ground-tyrant. Has white forehead and supercilium, pale ochre crown patch; rest of crown and upperparts pale brownish-grey; wings duskier, narrowly edged white (in fresh plumage remiges broadly tipped white); tail black, outer rectrices edged white; throat and chest greyish-white, becoming white on lower belly and vent; iris dark brown; bill long, black; legs black. Sexes alike. Juvenile has crown patch faint or absent, buff edgings in wing. Race *brevirostris* is darker than nominate, slightly smaller bill and wings. Voice. Short high-pitched bursts, "tsee tee tsee tseet".

Habitat. Stony slopes with little vegetation, near water; *puna* grassland and bogs. Mostly 2000-4500 m, also breeding at 500-1000 m S of N Chile; occasionally down to sea-level in S Chile, especially during inclement weather.

Food and Feeding. Insects. Mainly terrestrial, making short runs and hops, stopping suddenly and standing erect; less frequently, sallies from the ground or a rock; also searches in leaf litter and plants, flicking aside leaves for hidden insects.

Breeding. Oct-Feb; possibly double-brooded. During display, male flies high up with dangling legs, comes to a stall, then drops to ground. Nest an open cup made of grass, lined with feathers, placed in crack or cavity in rock, under stone, in rodent burrow, or directly on ground. Clutch 3 eggs, sometimes 2 or 4. No other information.

Movements. Migratory; spends austral winter (Mar-Sept) farther N, into Andes of W Bolivia and Peru.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. One of the most abundant ground-tyrants in C Chile. Breeding range possibly slightly more extensive; scattered reports of potential breeders in Boliva (Oruro) and S Peru. Occurs e.g. in all national parks in Patagonian Andes; in non-breeding season also in Eduardo Avaroa National Park, in Bolivia.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chebez (1994), Chesser (1997), Clark (1986), Clements & Shany (2001), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2000, 2003), Fjeldså & Krabbe (1990), Flores & Capriles (1998), Humphrey *et al.* (1970), Johnson (1967), Joseph (1996), Marín (2004), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Olrog (1972), de la Peña (1988), Ridgely & Tudor (1994), Rocha & Quiroga (1996, 1998), Stotz *et al.* (1996).

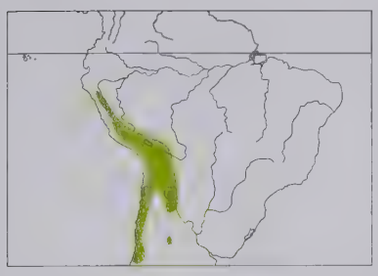
323. Rufous-naped Ground-tyrant

Muscisaxicola rufivertex

French: Dormilon à calotte rousse **Spanish**: Dormilona Nuquirroja
German: Rotnacken-Grundtyrann

Taxonomy. *M[uscisaxicola] rufivertex* d'Orbigny and Lafresnaye, 1837, Cobija, Antofagasta, Chile.

Race *occipitalis* possibly a separate species, may occur together with *pallidiceps* (in non-breeding season) and no intermediates between them are known; further research required. Three subspecies recognized.



Subspecies and Distribution.

M. r. occipitalis Ridgway, 1887 - Peru (except SW) and NW Bolivia (La Paz, Cochabamba).

M. r. pallidiceps Hellmayr, 1927 - SW Peru (Arequipa S to Tacna), N Chile (Arica S to Antofagasta), SW Bolivia and NW Argentina.

M. r. rufivertex d'Orbigny & Lafresnaye, 1837 - breeds in mountains of Chile (Atacama S to Colchagua) and W Argentina (Sierra de Mendoza and Córdoba).

Descriptive notes. 15·5-18 cm. The palest and purest grey ground-tyrant. Nominate race has faint white supercilium and broken eyering, bright cinnamon or orange-rufous crown patch (sometimes surprisingly inconspicuous and concealed); rest of head and upperparts pale grey, lower rump black; wings dusky grey; tail dusky, outer web of outer feathers edged white; pale grey below, throat and belly whitish; iris dark brown; bill long, thin, slightly downcurved at tip, black; legs

black. Sexes alike. Juvenile has crown patch duller and browner, wing-coverts edged cinnamon. Race *occipitalis* is noticeably larger than nominate, crown patch darker chestnut, broader and more prominent white supercilium, little or no pale edging in tail; *pallidiceps* is smaller, paler ashy grey above, supercilium narrower, crown patch paler, tail blacker. Voice. Call a loud "tweet" and "tit"; male during display utters thin, high-pitched "twee-it".

Habitat. Grassland and grassy or ploughed pastures, often near rocky slopes and ravines, cliffs and edges, sometimes dry desert; may roost in rocky caves. At 2200-4500 m; race *occipitalis* 3000-4500 m; *pallidiceps* 2200-4000 m, in austral winter 300-1000 m.

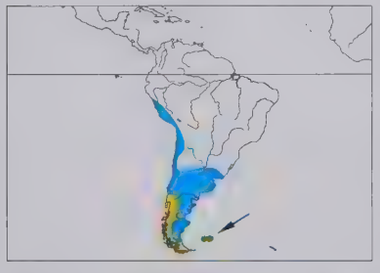
Food and Feeding. Insects. Mainly terrestrial, making short runs and hops after prey, stopping suddenly and standing very erect; less frequently, sallies from the ground or a rock. Generally solitary; often forms small flocks in non-breeding period.

Breeding. Nests found in Nov-Jan in Argentina; eggs in Sept in C Chile; nestlings in Sept and Dec in S Peru. Displaying male flies to c. 16 m, hangs vertically with wings stretched fully above back, calls, and drops to ground. Nest made of plant material, internal open cup of small straws, lined with feathers and hair, placed in crack between rocks; one nest in Argentina had external diameter 11 cm, internal diameter 6·5 cm, depth 4·5 cm, one in Peru (race *occipitalis*) with external diameter 14 cm, internal diameter 7 cm, depth 5 cm. Clutch 3 eggs; no information on incubation and fledging periods. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. Not well known. Race *occipitalis* apparently resident; *pallidiceps* an altitudinal migrant, descending to as low as 300 m in austral winter, may also migrate N (joining *occipitalis*); nominate race may also be an altitudinal migrant. No definitive evidence of long-distance migration.

Status and Conservation. Not globally threatened. Uncommon to locally common. The most abundant ground-tyrant in SW Peru. Occurs in Machu Picchu Historical Sanctuary and Huascarán National Park, both in Peru, and Eduardo Avaroa National Park, in Bolivia.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chapman (1921), Chebez (1994), Chesser (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Jaramillo (2003), Johnson (1967), Koepcke (1970), Landbeck (1877), Marín (2004), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001), Zimmer (1930, 1937a).



324. Dark-faced Ground-tyrant

Muscisaxicola maclovianus

French: Dormilon bistré **German**: Maskengrundtyrann **Spanish**: Dormilona Carinegra

Taxonomy. *Sylvia macloviana* Garnot, 1829, Falkland Islands.
Two subspecies recognized.

Subspecies and Distribution.
M. m. mentalis d'Orbigny & Lafresnaye, 1837 - S Chile (Llanquihue S to Cape Horn) and S Argentina (Neuquén and Río Negro S to Tierra del Fuego); winters N to N Peru, NE Argentina and Uruguay.
M. m. maclovianus (Garnot, 1829) - Falkand Is.

Descriptive notes. 15-16·5 cm. Generally shorter-billed than other ground-tyrants, accentuated by small and rounded appearance. Has forehead, lores and cheek blackish, crown dull chestnut-brown; upperparts dark brown or smoky brown, wings duskier, lower rump and tail black, outer web of outermost rectrix whitish; grey below, belly and crissum white; iris dark; bill and legs black. Sexes alike. Juvenile has throat streaked, wing-coverts edged buffy. Race *mentalis* is considerably smaller than nominate. Voice. Alarm call a series of loud "cheep" and rapid "tu" or "chee-tú"; territorial song reported as a warbling series of notes; flight call a discreet "zilip".

Habitat. Open meadows near forest and woodland edge and high Andean slopes; also marshy places in valleys and prairie-like habitat in vicinity of rivers; sometimes associated with cushions of *Azorella* at high elevations. In non-breeding season, occurs in grassland, pastures, sandy deserts, beaches, and on and near dry kelp beds and floating seaweed; sometimes in irrigated fields. Below 1200 m, rarely to 2500 m.

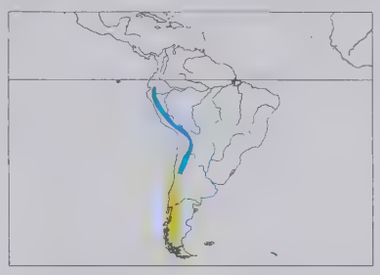
Food and Feeding. Insects. Mainly terrestrial, making short runs and hops after prey, stopping suddenly and standing erect; sometimes hovers for long periods with tail spread, seeking prey on the ground; occasionally perches on trees and telephone poles. Usually solitary or in pairs, but often forms loose flocks (of up to 100 individuals) in non-breeding season.

Breeding. Sept-Mar (race *mentalis*); Oct-Dec in Falkland Is (nominate); possibly double-brooded. Displaying male flies up c. 16 m, then drops to ground, where it raises and lowers wings in front of female. Nest an open cup made of grass, sometimes with rootlets, lined with feathers, wool, etc., placed in crack or hollow between rocks; one nest in Falklands (nominate race) a deep cup with diameter 7·5 cm. Clutch 2-3 eggs; no information available on incubation period; fledging period 18 days.

Movements. Resident in Falkland Is. Mainland race *mentalis* migratory, spends austral winter (Apr-Oct) along coasts W to N Chile and Peru (N to La Libertad), and NE to N Argentina (Jujuy, Córdoba, Entre Ríos and Buenos Aires) and Uruguay. Vagrant recorded on South Georgia in Sept 1994.

Status and Conservation. Not globally threatened. Common. Most numerous ground-tyrant in S part of Tierra del Fuego in austral summer. Nominate race in Falkland Is estimated at 4000-8000 pairs in 1983-93; domestic cats a major predator. High-elevation populations presumably at lower risk than are grassland populations, as grasslands are disappearing through overgrazing and agriculture.

Bibliography. Araya & Chester (1993), Arballo (1990), Canevari *et al.* (1991), Cawkell & Hamilton (1961), Chebez & Bertonatti (1994), Clark (1986), Clements & Shany (2001), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2000, 2003), Fjeldså & Krabbe (1990), Harris (1998), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Joseph (1996), Landbeck (1877), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), Olrog (1972), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Shirihai (2002), Stotz *et al.* (1996), Woods (1988), Woods & Woods (1997).



325. White-browed Ground-tyrant

Muscisaxicola albilora

French: Dormilon à sourcils blancs **Spanish**: Dormilona Cejiblanca
German: Rostkappen-Grundtyrann

Taxonomy. *Muscisaxicola albilora* Lafresnaye, 1855, Santiago, Chile.
Has in the past been considered closely related to, and perhaps conspecific with, *M. juninensis*.
Monotypic.

Distribution. Breeds in C & S Chile (Aconcagua S to Magallanes) and CW & SW Argentina and E Río Negro; winters N to W Bolivia, Peru and Ecuador.

Descriptive notes. 16·5-17 cm. Has prominent long, narrow white supercilium, tawny crown merging into rufous on hindcrown; upperparts greyish, wings dusky grey; tail black, outer web of outer pair of feathers whitish; dull pale grey below, vent whitish; iris dark brown; bill long, dusky; legs dusky. Differs from *M. juninensis* in slightly larger size, darker crown, more obvious supercilium. Sexes alike. Juvenile has whole crown brown, tertials and wing-coverts narrowly edged dull rufous. Voice. Song an excited "tstet, tseek, tut, tsk, tchk"; flight call "tseet", contact call "tut"; during aerial display rarely "clet ip".

Habitat. *Puna* grassland, pastures and stony hillsides, occasionally near marshes and lakes; also barren rocky slopes nearly free of vegetation near water; in pastures and other areas with partly wooded terrain during migration. Often associated with marshes or lakes in non-breeding range. At 1500-2500 m; in non-breeding season 2500-4000 m.

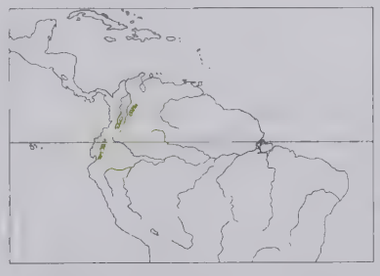
Food and Feeding. Insects. Mainly terrestrial, making short runs and hops after prey, stopping suddenly and standing erect; less frequently, sallies from the ground or a rock. Usually solitary; loose flocks during migration.

Breeding. Eggs in Oct-Jan in Chile; nests found in Nov and Feb in Argentina. During aerial display, flies up slowly, with legs dangling and tail spread, before dropping to ground; aggressive behaviour includes one or both wings raised, tail fanned, and crown erect; sometimes bows, sometimes flies with shaking wings. Nest an open cup made of grass, lined with feathers, placed in crack or hollow between rocks. Clutch 2-3 eggs. No other information.

Movements. Migratory; spends austral winter (Apr-Sept) farther N, to Bolivia, Peru and Ecuador, and recently recorded on Gorgona I (off SW Colombia). Accidental in Falkland Is.

Status and Conservation. Not globally threatened. Fairly common. Generally numerous on Chilean nesting grounds, especially around Santiago, where the most numerous breeding ground-tyrant. Occurs in all national parks along S Andes. In non-breeding season fairly common in Bolivia and Peru, uncommon in Ecuador (but regular on various Ecuadorian mountains).

Bibliography. Araya & Chester (1993), Butler (1979), Canevari *et al.* (1991), Cawkell & Hamilton (1961), Chesser (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Jaramillo (2003), Johnson (1967), Joseph (1996), Marín (2004), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nellar (1993), Olrog (1972), Ortiz von Halle (1990), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001), Woods (1988).



326. Plain-capped Ground-tyrant

Muscisaxicola alpinus

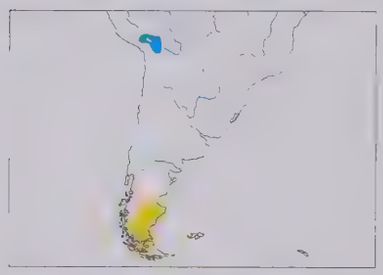
French: Dormilon à grands sourcils **Spanish**: Dormilona Gris
German: Weißbrauen-Grundtyrann
Other common names: Paramo Ground-tyrant

Taxonomy. *Taenioptera alpina* Jardine, 1849, Quito, Ecuador.
Formerly considered conspecific with *M. griseus* and *M. cinereus* by some authors; recent molecular work supports treatment as distinct species. Races weakly differentiated. Three subspecies recognized.

Subspecies and Distribution.
M. a. columbianus Chapman, 1912 – NC Andes of Colombia.
M. a. quesadae Meyer de Schauensee, 1942 - E Andes of Colombia (Boyacá, Cundinamarca).
M. a. alpinus (Jardine, 1849) - Ecuador.

Descriptive notes. 18-19 cm. Has long and broad white supercilium extending beyond eye, small white area below eye; lores dusky; greyish-brown above, crown tinged sepia-brown; wings duskier, some pale edging on wing-coverts; tail blackish, outer rectrix narrowly edged white; greyish-white below, whiter on throat and belly; iris dark brown; bill somewhat short and thin, black; legs black. Differs from *M. cinereus* mainly in larger size, darker and browner upperparts, whitish supercilium extending slightly beyond eye. Sexes alike. Juvenile has wing-coverts and inner remiges narrowly tipped and edged cinnamon, belly and vent tinged buff, whitish streaking below, feathers of crown and back with faint darker tips. Race *columbianus* is nearly inseparable from nominate, but slightly darker on back (closer to crown colour), greyer on belly; *quesadae* may average slightly smaller. Voice. Generally silent; weak plaintive note (Colombia), also occasional soft "tik" note.

Habitat. Arid montane scrub, *puna* and *páramo* grasslands, often where rocky; also, stands of *Espeletia* or areas of low vegetation from tree-line up to snow-line. Mainly 3300-4700 m, occasionally down to 800 m.



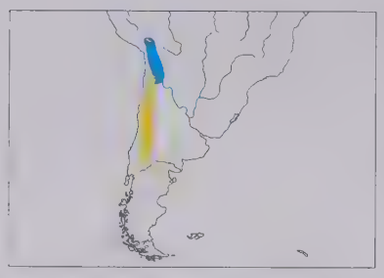
Food and Feeding. Insects. Feeds on ground, making run or hops, often suddenly stopping, and standing erect; sometimes sallies to ground from low perch; often flicks tail. Sometimes takes slightly elevated perch, e.g. on rock or wall. Usually solitary; in non-breeding season regularly in loose flocks of up to 30 individuals, occasionally in association with other ground-tyrants or other *puna*-zone birds.
Breeding. Sept-Dec in Colombia (Boyacá) and Aug in Ecuador. Displaying male repeatedly hovers, stalls and drops. Nest a sparsely lined grass and root mass, placed in hole or crevice under rock. Clutch 4 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally fairly common to common. Especially numerous at higher elevations in Cotopaxi National Park, in Ecuador. Rather uncommon in Colombia. Occurs in Puracé National Park, in Colombia, and Las Cajas National Recreation Area, in Ecuador.
Bibliography. Butler (1979), Chapman (1917c), Chesser (2000), Clements & Shany (2001), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Parker *et al.* (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Vuilleumier (1994), Williams & Tobias (1994).

327. Cinnamon-bellied Ground-tyrant

Muscisaxicola capistratus

French: Dormilon à ventre roux **German**: Zimtbauch-Grundtyrann **Spanish**: Dormilona Canela

Taxonomy. *Ptyonura capistrata* Burmeister, 1860, foot of Sierra de Mendoza, Argentina.
Monotypic.
Distribution. Breeds extreme S Chile and S Argentina; migrates N as far as S Peru.



Descriptive notes. 16·5-18 cm. Has black forehead, bright rufous-chestnut mid-crown and hindcrown (pattern usually conspicuous in field); nape and back dusky grey or brownish-grey, wings dusky, feathers edged pale white; tail black, outer rectrices edged white; throat whitish, greyish-buff on chest becoming cinnamon-rufous or rufous-buff on belly, darker on flanks and vent (pattern often not conspicuous in field); iris dark; bill and legs black. Sexes alike. Juvenile is paler on belly and crown, feathers narrowly tipped blackish, breast faintly mottled, wings edged buff. Voice. High-pitched "wee tee, wee tee tee" and "wee tee tee tee", also longer "weetee weetee weeteewee wee wee".
Habitat. Occurs in rolling hills with scattered bushes and sparse grass, often adjacent to rocky outcrops and slopes, rocky canyons with grassy patches, and pastures; prefers flat, short and moist grass. Also cushion bogs and lakeshores in non-breeding season. May roost in caves. Breeds below 500 m; in non-breeding season, however, occurs in elevational range of 2000-4000 m, and rarely up to 4700 m.
Food and Feeding. Insects. Mainly terrestrial, making short runs and hops after prey, stopping suddenly and standing erect; less frequently, sallies from the ground or a rock. Regularly flocks on wintering grounds.
Breeding. Little known. Sept-Mar; eggs in Nov-Dec; nests found in Oct, Nov and Jan in Tierra del Fuego. During aerial display flies up, higher than most congeners, hovers with legs dangling and tail spread, wings make whirring sound before birds drops to ground; in high wind, performs closer to ground level; exposes crown, ruffles chest and flanks, when aggressive. Nest an open cup made of grass, lined with feathers, placed in crack or hollow between rocks, sometimes in abandoned rodent burrow. Clutch 3 eggs. No other information.
Movements. Migratory; spends austral winter (Apr-Oct) mainly in Peru (N to Arequipa), rarely in W Bolivia.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Breeds in Laguna Blanca National Park, in Argentina, and Torres del Paine National Park, in Chile. Earlier observers reported the species as locally common, but in late 1980s reported as rare and local. Population appears either to fluctuate greatly or to have decreased markedly in recent decades.
Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chesser (1997), Clark (1986), Clements & Shany (2001), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Joseph (1996), Keith (1970), Marín (2004), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nellar (1993), Nores *et al.* (1983), Olrog (1972), de la Peña (1988), Ridgely & Tudor (1994), Rocha & Quiroga (1996), Stotz *et al.* (1996), Vuilleumier (1994), Zapata (1967).

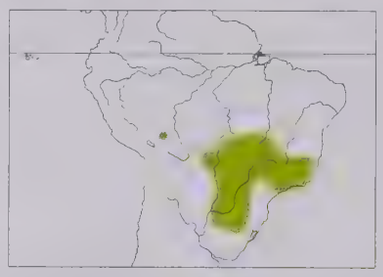
328. Black-fronted Ground-tyrant

Muscisaxicola frontalis

French: Dormilon à front noir **Spanish**: Dormilona Frentinegra
German: Schwarzstirn-Grundtyrann

Taxonomy. *Ptyonura frontalis* Burmeister, 1860, foot of Sierra de Mendoza, Argentina.
Monotypic.
Distribution. High cordilleras of Chile (Antofagasta S to Santiago) and C Argentina (W Mendoza S to W Río Negro, with isolated population on Somuncará Plateau); winters N to S Peru and W Bolivia.
Descriptive notes. 18 cm. Striking head pattern. Has forecrown black, blackish-chestnut toward hindcrown, with conspicuous white lores and broken eyering; upperparts ashy grey, wings duskier, tail black, outer web of outermost rectrix whitish; pale greyish-white below; iris dark brown; bill slim, distinctly decurved at tip, black; legs black. Sexes alike. Juvenile has forecrown sooty, wing-coverts edged pale buff. Voice. Unknown.
Habitat. *Puna* grassland and stony hillsides with sparse vegetation, often near water. Mostly 2500-4300 m, rarely down to 1800 m.
Food and Feeding. Diet consists of insects. Mainly terrestrial, making short runs and hops after prey, stopping suddenly and standing erect (though less so than most of its congeners); less frequently, sallies from the ground or a rock. In winter solitary, sometimes roosting in caves with *M. rufivertex*.

Breeding. Oct-Mar; nestlings in Dec in Chile. One nest found, in deep crack between rocks, contained 2 chicks. No other information available.
Movements. Migratory; spends austral winter (Apr-Sept) mainly in W Bolivia and S Peru (Arequipa), although not recorded there in great numbers.
Status and Conservation. Not globally threatened. Rare to uncommon; locally more common, e.g. around Portillo ski resort or at El Yeso Reservoir, in C Chile. In austral winter, apparently uncommon in W Bolivia and rare in S Peru.
Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chesser (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Jaramillo (2003), Johnson (1967), Joseph (1996), Marín (2004), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Tudor (1994), Rocha & Quiroga (1996, 1998), Stotz *et al.* (1996).



Genus *GUBERNETES* Such, 1825

329. Streamer-tailed Tyrant

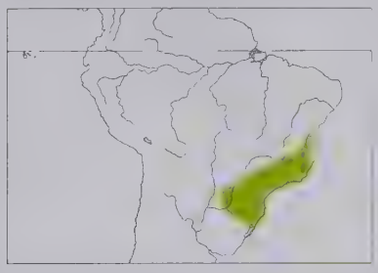
Gubernetes yetapa

French: Moucherolle yétapa **German**: Kehlband-Schleppentyrann **Spanish**: Yetapá Grande

Taxonomy. *Muscicapa yetapa* Vieillot, 1818, Río Plata, Paraguay.
Anatomical considerations indicate that closest relatives may be somewhat similar *Muscipipra* and very different *Neoxolmis*. Monotypic.
Distribution. NW Bolivia (upper R Beni) and SC Brazil (S Mato Grosso, extreme S Bahia S to W Rio Grande do Sul) S to E Paraguay and NE Argentina (Chaco, Corrientes, Misiones).

Descriptive notes. 35-38 cm; 42 cm (including tail). Male has pale grey forecrown and supercilium; above, mostly pale grey with dark brown shaft streaks; wings blackish, patch of cinnamon-rufous at base of primaries (conspicuous stripe in flight), tertials edged light brown or sandy-brown; tail long, graduated and very deeply forked, blackish; throat white, sharply outlined on side of neck and across upper chest by dark chestnut pectoral collar; breast and sides pale grey with faint dark shaft streaks, becoming white on belly; iris dark; bill stout, black; legs black. Female is smaller, shorter-tailed and slightly duller. Juvenile considerably duller, with upperparts blotched brown; much shorter tail. Voice. Call a harsh "wurreep", repeated multiple times when hovering over foraging area; also fuller descending phrase of 2 or 3 notes, "jew-jew-jew"; also has a dawn song. During vigorous duetting diplay, one individual (possibly female) begins by uttering clearly whistled "tewear-TEE-tear" 2-4 times in rapid succession while other (perhaps male) utters a warbled "tea-whittle, tea-whittle..." in syncopation, one or both birds also occasionally making pop sound with bill.
Habitat. Buriti palm groves, damp grasslands and marshy terrain near streams, always with some shrubbery nearby. Mostly below 1100 m.
Food and Feeding. Diet consists of insects. Usually in pairs, less often small family groups, perching conspicuously atop bushes and low trees, often at edges of gallery woodland. Sallies out, often long distances, after insects, long tail whipping behind in flight; often hunts low over marshy areas, occasionally pouncing to ground or sallying downward against vegetation to take large insects.
Breeding. Pairs displaying in Jul, Brazil. During duetting display, members of pair perch 10-50 cm apart, facing one another or away; each alternately lowers head while raising and fanning tail above horizontal, then raises head, lowers tail, and excitedly raises both wings high overhead, while calling and bill-popping excitedly in syncopation. Nest not well described, apparently an open cup.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Relatively common at Beni Biosphere Reserve, in Bolivia, and also occurs in San Rafael, San Luis and Ybycuí National Parks, all in Paraguay, and Patrimônio Natural do Caraça Special Reserve and Brasília and Serra da Canastra National Parks, in Brazil.
Bibliography. Andors & Vuilleumier (1998), Canevari *et al.* (1991), Carriker (1935), Cory & Hellmayr (1927), Dubs (1992), Fitzpatrick (1980c, 1981, 1985a), Hayes (1995), Hennessey, Herzog & Sagot (2003), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Parker *et al.* (1991), de la Peña (1988), Ridgely & Tudor (1994), Saibene *et al.* (1996), Schubart *et al.* (1965), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Wetmore (1926).

Genus *MUSCIPIPRA* Lesson, 1831



330. Shear-tailed Grey Tyrant

Muscipipra vetula

French: Moucherolle à queue-de-pie **German**: Kerbschwanztyrann **Spanish**: Viudita Coluda

Taxonomy. *M[uscicapa] vetula* M. H. K. Lichtenstein, 1823, São Paulo, Brazil.
Relationships uncertain, but closest allies seem to be *Gubernetes* and *Neoxolmis*, on basis of anatomical studies. Monotypic.

Distribution. CE & SE Brazil (S Bahia, C Minas Gerais and Espírito Santo S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones, Corrientes).

Descriptive notes. 22-5 cm. Plumage is mostly rather dull dark grey; dusky auriculars forming a weak mask, faint streaking on crown and back; wings and tail dusky blackish; long, slender tail is deeply notched, underside of outer rectrices edged pale whitish; white chin and throat, pale grey belly; iris blackish; bill and legs dusky. Sexes alike. Juvenile has crown, back and wing feathers scaled white. Voice. Usually silent; occasionally utters a "pup-pup-pup" or a disyllabic whistle, "jew-bewt".

Habitat. Inhabits borders of humid and montane forest and secondary woodland; to a lesser extent, moves out into adjacent clearings or natural grassland. Mostly found below 2200 m, and mainly at 1000-2200 m.

Food and Feeding. Insects. Usually in pairs, less often in groups of up to 5-6 birds. Usually hunts near canopy, perching on high exposed branches; less often perches lower, sometimes even dropping to the ground. Sallies after passing prey with graceful undulating flight, often for long distances.

Breeding. Nov in Rio Grande do Sul. Nest is a tall, open cup made of coarse grass and twigs, covered with dry moss and lined with fine grass, less than 1 m above ground in 2-m tall, shrubby *Baccharis*-dominated vegetation amidst *Araucaria* forest. Clutch 3 eggs.

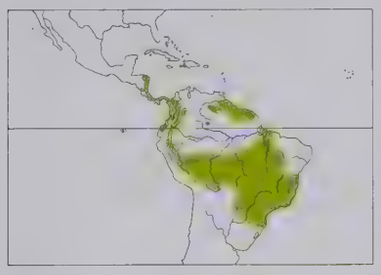
Movements. Resident, but little known.

Status and Conservation. Not globally threatened. Rare to uncommon. Regular in Intervales State Park and common at forest borders and in canopy in Patrimônio Natural do Caraça Special Reserve, both in Brazil. Also occurs in Mbaracayú Forest Nature Reserve, in Paraguay, and Augusto Ruschi Biological Reserve, Mata dos Godoy State Park (Paraná) and Caparaó and Itatiaia National Parks, all in Brazil.

Bibliography. Canevari *et al.* (1991), Chebez (1994), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Darrieu (1987), Ferreira de Vasconcelos & Melo-Júnior (2001), Fitzpatrick (1985a), Fontana *et al.* (2000), Hayes (1995), Isler (2000), Lanyon (1986a), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Navas & Bó (1988), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Schmidtuz *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993).

PLATE 40

inches 3
cm 8



Genus *COLONIA* J. E. Gray, 1827

331. **Long-tailed Tyrant**

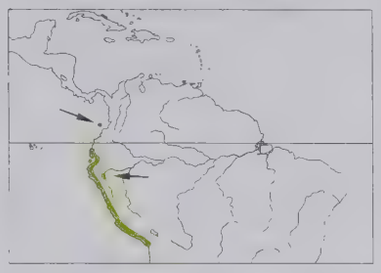
Colonia colonus

French: Moucherolle à longs brins **Spanish**: Mosquero Colilargo
German: Weißkappen-Schleppentyrann

Taxonomy. *Muscicapa colonus* Vieillot, 1818, Paraguay. Affinities uncertain; probably belongs in subfamily Fluvicolinae, but further study required. Five subspecies recognized.
Subspecies and Distribution.
C. c. leuconota (Lafresnaye, 1842) - SE Honduras and E Nicaragua S to W Colombia and W Ecuador.
C. c. fuscicapillus (P. L. Sclater, 1861) - E Andes of Colombia, N Ecuador and extreme NE Peru (mouth of R Curaray).
C. c. poecilonota (Cabanis, 1848) - SE Venezuela (S of R Orinoco and in Amazonas) and the Guianas.
C. c. niveiceps J. T. Zimmer, 1930 - SE Ecuador, Peru (San Martín S to N Puno) and N Bolivia (S to Cochabamba).
C. c. colonus (Vieillot, 1818) - C & E Brazil (from Marajó I and S Maranhão S to S Mato Grosso do Sul and N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. Male 23-28 cm, female 18-22 cm; 15-18 g. Male nominate race dull black, with white forehead and forecrown; whitish rump; belly greyish-black; central tail feathers elongated (up to 13 cm beyond rest), widening slightly towards tip (before moult, one or both feathers often worn or broken); iris dark; bill short and wide, black; legs black. Female similar, but paler and greyer, belly mottled white, back stripe greyer, crown darker, shorter tail streamers. Juvenile paler, sooty grey with pale grey belly, faint whitish stripe bordering crown, central rectrices broader and barely projecting. Races vary in intensity and extent of white on head, amount of white on back, and body and bill size: *leuconota* similar to *poecilonota* but has bill less heavy and crown darker, more sooty grey; *fuscicapillus* has darker back, clear white rump, female with darker crown; *poecilonota* is larger overall, with heavier bill, also blacker, with crown-feathers ashy grey with black central streaks, and irregular white stripe down mid-back; *niveiceps* has pale silvery grey crown. Voice. Soft, rising "tuweee" or "wheeet" while flicking tail up, sometimes calls 2-3 times in quick succession; male song a longer "twee-la, twee-la, twee-la"; musical, humming "druu", accompanied by whipping of long tail; sharp, sibilant "chip" in interactions. During courtship chases "prrri, bi-bibi".
Habitat. Borders of tropical and upper tropical humid forest and secondary woodland, edges of gallery forest, *Cecropia* zone in early-successional forest, recent clearings, active and abandoned plantations with scattered dead snags, forested borders along waterways, treefall gaps inside forest, and snags in upper canopy over primary forest. Usually below 1200 m, rarely to 1800 m.
Food and Feeding. Of 37 prey items in SE Peru, 60% were hymenopterans, 31% coleopterans; in Costa Rica, 67% of prey items were sweatbees (*Trigona*). Specializes on stingless bees (sweatbees) in many areas. Perches conspicuously for minutes on end, high on exposed dead snags or open branches, usually in pairs or family groups; flicks tail-streamers up and down while calling. Makes aerial sallies of 1-10 m to hawk insects, usually returning to same or nearby perch.
Breeding. Birds in breeding condition and nests located Mar-Jul in Central America, Colombia and Venezuela; in Argentina, pair feeding fledgling in Oct and pair seen to enter old woodpecker (Picidae) hole in Nov. Pair maintains small permanent territory around favourite snag or trunk that serves for nesting and foraging; rarely venture far away. Partners chase each other during courtship. Nest a thick mat of compound-leaf rachises, placed inside tree cavity such as old woodpecker hole or rotten knothole 8-30 m up in dead snag or burned trunk in exposed area; defended against other hole-nesting species; female roosts in cavity up to one week before laying. Clutch 2-3 eggs. No other information.
Movements. Mostly resident; apparently leaves extreme S of range for austral winter.
Status and Conservation. Not globally threatened. Fairly common to common. Somewhat local, requiring suitable dead stump with cavity, and nearby colonies of bees. Tolerant of converted habitats, and occurs in many national parks and other protected areas throughout its large range.
Bibliography. Anon. (1998a), Begazo (1995), Brooks *et al.* (1993), Canevari *et al.* (1991), Clements & Shany (2001), Cory & Hellmayr (1927), Fitzpatrick (1980c, 1985b), Fjeldså & Krabbe (1990), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Henderson (2002), Hilty (1997, 2003), Hilty & Brown (1986), Howell & Webb (1995a), Lanyon (1986a), Lowen *et al.* (1996), Monroe (1968), Narosky & Salvador (1998), de la Peña (1988), Pizo (1996), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robinson (1997), do Rosário (1996), Salaman (1994), Schönwetter & Meise (1968), Sick (1993, 1997), Skutch (1960, 1972), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Wetmore (1972), Williams & Tobias (1994), Zimmer (1930, 1937a).

Genus *MUSCIGRALLA*



d'Orbigny & Lafresnaye, 1837

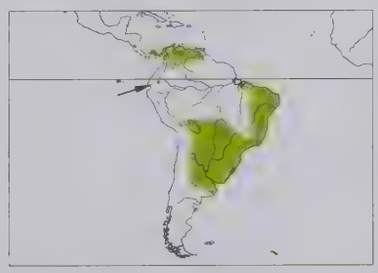
332. **Short-tailed Field-tyrant**

Muscigralla brevicauda

French: Moucherolle à queue courte **Spanish**: Dormilona Colicorta
German: Stummelschwanztyrann

Taxonomy. *M[uscigralla] brevicauda* d'Orbigny and Lafresnaye, 1837, Tacna, Peru.
Placed by early authors in Cotingidae or Formicariidae, on basis of tarsal scutes. Affinities within present family unclear; placed in or near *Muscisaxicola* by some, but coronal patch, long legs with aberrant scutellation, bare tibia, wing and tail shapes support current monotypic genus. Monotypic.
Distribution. SW Ecuador (Manabí S to Loja), N & W Peru (Amazonas, and down coast to Tacna) and N Chile (Arica); one specimen from SW Colombia (Gorgona I).

Descriptive notes. 11-11·5 cm. Plumage is brownish-grey above, short supraloral stripe white, semi-concealed yellow coronal patch; upper rump buffy, lower rump and uppertail-coverts rufous-chestnut; wings dusky, wing-coverts tipped whitish (two pale wingbars), remiges narrowly edged whitish; tail extremely short, dusky with narrow buff tips; throat, breast and belly whitish, grading to buffy on flanks; iris dark brown; bill dark brown to blackish; legs very long, flesh-coloured, bare even above "heel". Sexes alike. Voice. Song, usually from mound or low perch, occasionally during aerial display, a weak, sibilant "tizztizzz", sometimes preceded by a few "tik" notes.
Habitat. Arid coastal lowlands and arid intermontane valleys, preferring open, barren or sandy areas and dusty agricultural fields, ploughed areas with sparse weeds, and open ground with scattered bushes or low trees; most common near sea-level, but found at up to 1500 m.
Food and Feeding. Insects. Almost exclusively terrestrial; pursues insects on the ground by alternately running and pausing briefly, making short, rapid sallies or hops to snatch stationary or low-flying prey. Stance upright, appears nearly tailless.
Breeding. Feb-Jun in Ecuador. Song occasionally given during aerial display up to 20 m high. Nest cup-shaped, composed of uniform, dry, greyish grasses (blending with substrate), lined with finer grasses, placed on ground alongside gulley or on open flat ground, usually with some protection from above such as dead tree bough, brush pile, tufts of taller grass, or low stunted arrayan; sometimes constructs partial dome, with at least a third of cup open, in less protected situations. Clutch 3-5 eggs; incubation and nestling periods each c. 13-14 days. Success rate of c. 38-40% has been estimated.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Largest numbers along coast, especially numerous on Santa Elena Peninsula (Ecuador) and arid coastal zone of S Peru. Status in Chile unclear; possibly irregular breeder, dependent on suitability of conditions. Occurs in e.g. Cerro Blanco Forest Reserve, in Ecuador.
Bibliography. Ames (1971), Araya & Chester (1993), Best *et al.* (1993), Butler (1979), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick (1980c, 1985b), Jaramillo (2003), Johnson (1967), Koepcke (1970), Lanyon (1986a), Marchant (1960), Marín (2004), Meyer de Schauensee (1982), Ortiz von Halle (1990), Peredo & Miranda (2001), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Smith & Vuilleumier (1971), Stotz *et al.* (1996), Traylor (1977), Traylor & Fitzpatrick (1982), Warter (1965), Zimmer (1930).



Genus *MACHETORNIS* G. R. Gray, 1841

333. **Cattle Tyrant**

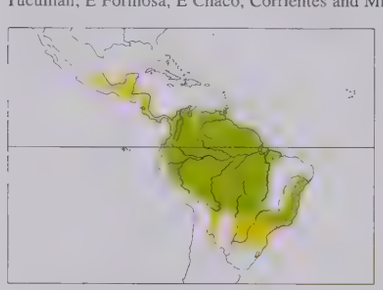
Machetornis rixosa

French: Moucherolle querelleur **German**: Graslandtyrann **Spanish**: Picabuey

Taxonomy. *Tyrannus rixosus* Vieillot, 1819, Paraguay.
Affinities uncertain; molecular and anatomical evidence suggests that superficial resemblance to *Tyrannus* is due to convergence. Race *obscurodorsalis* possibly better merged with *flavigularis*; overlaps with latter in Venezuela and does not appear to be evolutionarily distinct; closer examination necessary. Also, some specimens of nominate from NE Brazil (Piauí) closely approach *flavigularis*. Three subspecies currently recognized.
Subspecies and Distribution.
M. r. flavigularis Todd, 1912 - E Panama, N & E Colombia (N Chocó and upper R Sinú E to Guajira, S to S Bolívar) and N Venezuela (E to Guárico, W Anzoátegui and Delta Amacuro, S to N Bolívar).
M. r. obscurodorsalis Phelps, Sr & Phelps, Jr, 1948 - SW Venezuela (Barinas, W Apure and S Cojedes), E Colombia E of Andes (Norte de Santander S to S Meta and Vichada) and E Ecuador.
M. r. rixosa (Vieillot, 1819) - E & S Brazil (extreme NE Pará E to Rio Grande do Norte, and S to Rio Grande do Sul, also S from S Mato Grosso and Goiás), N & E Bolivia (Beni and Santa Cruz S to Tarija), Paraguay, most of N Argentina (S to San Luis, Córdoba and SW Buenos Aires) and Uruguay.

Descriptive notes. 19·5 cm. Nominate race is primarily pale olive-brown or sandy brown to caramel-brown above; head mostly pale brownish, more greyish on crown, bright scarlet-orange coronal patch (usually concealed), thin dusky eyestripe, slight dusky brownish or yellowish tinge in auricular area; wings olive-brown; tail yellowish-cinnamon or olive-brown, pale dingy tips (broader and more contrasting from ventral perspective); throat whitish; underparts, including underwing-coverts, mostly bright yellow, breast tinged ochraceous olive; iris dark red; bill thin, black, very short or no obvious rictal bristles; legs dark. Differs from superficially similar *Tyrannus* species in shorter, more rounded wings and, especially, long legs. Sexes similar; female may have buff wash on throat and chest, and stated by some authors to lack coronal

On following pages: 334. Piratic Flycatcher (*Legatus leucophaius*); 335. Rusty-margined Flycatcher (*Myiozetetes cayanensis*); 336. Social Flycatcher (*Myiozetetes similis*); 337. Grey-capped Flycatcher (*Myiozetetes granadensis*); 338. Dusky-chested Flycatcher (*Myiozetetes luteiventris*); 339. White-bearded Flycatcher (*Phelpsia inornata*); 340. Great Kiskadee (*Pitangus sulphuratus*); 341. Lesser Kiskadee (*Philohydor lictor*).



patch. Juvenile undescribed. Race *flavigularis* has throat more buffy yellow, perhaps less grey in crown than nominate, possibly also deeper yellow belly; *obscurodorsalis* is very like previous. Voice. Common call a brief series of thin, squeaky notes that rises in pitch, dawn song a short, repeated trilled whistle, "t'te'te'ree", "tip-tip, tsi-tsip-tsilíp-tsilíp tsirrrr" or "swee see dee", both much like typical vocalizations of *Tyrannus melancholicus* but said to be more strident. At dusk may also give more complicated and sustained series of squeaky "tic" notes and short trills that rise and fall in pitch.
Habitat. Drier semi-open to open habitats, including savanna, pastureland with scattered bushes and trees, agricultural areas, yards around houses, parks in urban areas, and occasionally sandy beaches; generally not found in woodland or forested areas. Primarily tropical lowland areas below 300 m, occasionally ranging to c. 1000 m; single vagrant observed at 3600 m in Venezuela (Mérida).
Food and Feeding. Insects. Usually forages in pairs or small groups. Semi-terrestrial; runs rapidly on ground, with upright posture, sometimes for considerable distances, in pursuit of insects disturbed by domestic animals, much like a *Muscisaxicola* ground-tyrant. Often remains on the ground or perched on back of cattle, horse or capybara (*Hydrochaeris hydrochaeris*) for extended periods, occasionally making quick sallies to the ground or air after flushed insect prey; occasionally hawks from elevated perch. Perches on lower branches of trees, on top of low bushes or on houses.
Breeding. Nest-building observed in Mar (Meta) and juveniles in Jul (lower R Sinú) in Colombia; season Jun-Oct (Guárico) and males in breeding condition in May (Bolívar and César Val) in Venezuela; nests in Oct-Jan in Argentina. Large, multi-chambered stick nest of Plain-fronted Thornbird (*Phacellodomus rufifrons*) appropriated, or builds own bulky ball-shaped grass nest well above ground; one nest in Argentina had external diameter 12 cm, height 7·5 cm, internal diameter 7 cm, depth 5 cm; shows some degree of aggression towards nesting associates and other species that approach nest. Clutch 3-4 eggs; in Argentina, incubation period 14·5 days, fledging 16 days. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Mostly resident; some dispersal or local movements occur. Populations of nominate race in S part of range migratory; reports of vagrants in Ecuador and as far N as Panama (Darién).
Status and Conservation. Not globally threatened. Fairly common to common. Tolerant of converted habitat, and occurs in many national parks and other protected areas throughout its large range.

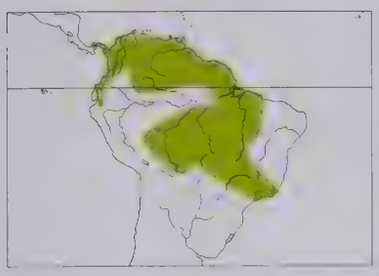
(1998a), Babarskas *et al.* (2003), Boano (1981), Camperi (1953), Carriker (1954, 1955, 1959), Canevari *et al.* (1991), Cory & Hellmayr (1927), Cruz & Andrews (1989), Di Giacomo (2004), Fitzpatrick (1980c, 1985a), Fjeldså & Maijer (1996), Friedmann (1927), Haffer (1975), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Klimaitis & Moschione (1987), Lanyon (1984a, 1986a), Lindell (1996), Lowen *et al.* (1996), Macdonald (1981), Mason (1985), Mobley (2002), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Naumburg (1930), de la Peña (1987, 1988, 1996), Phelps & Phelps (1948), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sibley & Ahlquist (1985c), Sick (1993, 1997), Stotz *et al.* (1996), Thomas (1979a), Traylor (1977), Traylor & Fitzpatrick (1982), Walker (1996), Warter (1965), Wetmore (1926).

Subfamily TYRANNINAE
Tribe TYRANNINI
Genus *LEGATUS* P. L. Sclater, 1859

334. **Piratic Flycatcher**
Legatus leucophaius

French: Tyran pirate **German**: Kurzschnabel-Maskentyrann **Spanish**: Mosquero Pirata

Taxonomy. *Platyrhynchos leucophaius* Vieillot, 1818, Cayenne.
Affinities uncertain. Possibly sister to *Myiozetetes*, on basis of syringeal morphology and fully enclosed globular nest. Molecular data give limited support that it is basal to clade including *Phelpsia* and *Philohydor*, while additional analyses indicate some affinity to *Pitangus* and *Myiozetetes*; link to *Myiozetetes* also suggested by piratical nesting behaviour, although observations suggest such behaviour and/or nest adoption either has evolved several times independently or is ancestral trait in the subfamily. Race *variegatus* indistinguishable from nominate on coloration alone; races probably meet in Honduras, though limits not well defined. Birds from S Brazil, Paraguay and Argentina described as race *albicollis*, but merely average somewhat larger. Additional molecular data and closer systematic examination needed to establish relationships, and to determine validity of races. Two subspecies currently recognized.
Subspecies and Distribution.
L. l. variegatus (P. L. Sclater, 1857) - E Mexico (S San Luis Potosí E to Tabasco, N & C Campeche and Quintana Roo to N Oaxaca and N Chiapas) to N & C Guatemala, Belize and Honduras.
L. l. leucophaius (Vieillot, 1818) - Nicaragua S to Panama and Colombia, then E to Venezuela and the Guianas, Trinidad and Tobago, and S through Ecuador, Peru, NW & C Brazil (S to Mato Grosso and N Rio Grande do Sul) and N & E Bolivia to C & E Paraguay and N Argentina (Salta, Jujuy and Tucumán; E Formosa, E Chaco, Corrientes and Misiones).



Descriptive notes. 14·5-17 cm; 23-26 g. Has forehead and crown blackish, semi-concealed yellow coronal patch; prominent and fairly broad supercilia, confluent on forehead and encircling crown, dull whitish (sometimes with faint yellow tinge), faintly streaked greyish posteriorly; lores and auriculars dusky brownish, dusky moustachial stripe, white malar region with some greyish flecking, narrow pale submalar streak; upperparts deep greyish-brown or dark olive-brown, most feathers with fairly distinct pale margins, uppertail-coverts usually with fairly prominent rusty, cinnamon or fulvous edging; wings brownish-black, median wing-coverts with fairly distinct whitish terminal margins, greater coverts and secondaries also with whitish edging (much broader on tertials, almost absent towards base of outer secondaries), primaries with very narrow pale greyish-brown edging; tail dusky brown or blackish-brown; outer webs of rectrices often with narrow light olive or rufous edging (nearly white or yellowish-white on outermost rectrices), inner webs with pale greyish-brown, rusty or fulvous edging; chin and throat pure whitish; underparts largely yellowish-white or very dull pale yellow, breast, sides and flanks with broad, somewhat diffuse brownish or olive streaking, undertail-coverts with some faint dusky streaking; iris brown; bill short, stubby, rather broad, brownish-black, browner base of lower mandible, rictal bristles very short; legs dusky. Sexes alike, female on average slightly smaller than male. Juvenile is essentially like adult, but lacking any yellow on crown, crown feathers lightly tipped cinnamon, supercilium pale buff or buffy white, broad cinnamon terminal margins on median and greater wing-coverts, rusty edging on rectrices, paler underparts nearly or completely unstreaked. Race *variegatus* is significantly larger than nominate. Voice. Rather conspicuous vocally during breeding period; male song, often repeated tirelessly from exposed perch in canopy, a bright, clear, yet petulant and whiny "wheé-yéé" or slurred "swee-u" whistle, often followed by pause of 1-2 seconds and then short, tremulous, rising "pír-ri-ri-ri-ree"; also "de-di-di-di-di", rolled "ji-ji-jit" or persistent "whee di-weet"; also longer, sometimes prolonged series of emphatic, piping, rising and falling "whii-whii-whii" or "pee-pee-pee" whistles; calling can continue for long periods, often persists through hottest part of day; alarm a rapidly repeated sharp, low "dee"; also said to emit rarely a frog-like call consisting of c. 15 "reek" notes in 3 seconds, context uncertain.
Habitat. Tall second growth and gallery forest, lighter humid woodland and evergreen forest borders, edges of secondary woodland, agricultural areas, and forest clearings that retain at least some scattered tall trees, also hedges. Mostly below 1000 m, but observed as high as 1500 m and rarely as high as 1850 m in Central America, and at 1700 m in W Colombia.
Food and Feeding. Insects, e.g. dragonflies (Odonata); also fruit. Adults said to be almost entirely frugivorous, with copious small berries and green catkins of *Cecropia*, when fruits abundant. Alone or in pairs; often perches conspicuously at upper to middle levels on exposed branch, often atop bare snags; prefers to remain at higher levels in canopy. Takes flying insects by aerial hawking.
Breeding. Breeding times require further documentation: in Venezuela, birds in breeding condition by Feb (Barinas), Mar-Apr (S & E Bolívar and Huila) and Mar-Aug (Guárico); occupied nests found in Feb-Aug in Trinidad and Oct-Dec in Argentina; Aug-Dec in SE Peru. No nest built; instead, usurps fully completed domed or pendent nest of various other species as much as ten times its own weight, especially icterids, *Phacellodomus* thornbirds, and *Pachyramphus* and several other tyrannids (including *Tolmomyias*, *Rhynchocyclus*, *Pitangus*, *Myiozetetes*); nest appropriation achieved by incessant harassment through aggressive diving attacks, egg-tossing, and sometimes nestling removal, to the point of complete abandonment by rightful owners; tends to adopt previously abandoned globular nests of more defensive nest-builders *Pitangus* and *Myiozetetes*; often adds dead leaves to interior of stolen or adopted nest. Clutch 2-3 eggs, sometimes 4; incubation by female alone, period 16 days; chicks brooded by female, fed by both parents, fledging period 18-20 days. Some migrant populations may breed both in Cetral America and in Amazonia.
Movements. At least partially migratory in both N & S parts of range. Although details not well known, it appears that Central American breeders move to N South America and Amazonia from about late Sept to early Jan; influx of migrants most numerous in Rancho Grande area of Venezuela from Mar to Jun, and perhaps later. Breeding population arrives S Costa Rica in late Jan to early Feb and up to 2-4 weeks later in areas farther N, departing by late Sept to early Oct. Apparently leaves Panama from late Sept to Dec as fruit becomes increasingly scarce during peak of rainy season; returns first to Pacific side of Canal Zone (where fruits tend to ripen earlier) by late Jan, but not until Feb-Mar on more rainy Caribbean side (fruits ripen later). Present in SE Peru from mid-Aug to Feb-Mar; in Argentina and S Brazil roughly Sept-Mar. Seasonal abundance and movements require closer study throughout species' range.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Has large range covering most of Middle America and most of N & C South America. Occurs in many national parks and other protected areas throughout range.

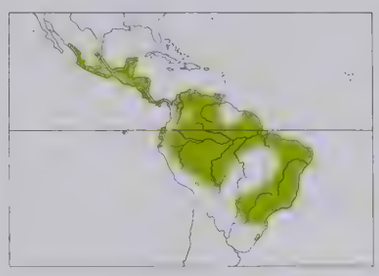
(1998a), Binford (1989), Birdsley (2002), Canevari *et al.* (1991), Carriker (1910), Chesser (1997), Clements & Shany (2001), Cory & Hellmayr (1927), ffrench (1991), Fitzpatrick (1985a), Fjeldså & Maijer (1996), Haverschmidt (1968, 1973), Haverschmidt & Mees (1994), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Ihering (1900), Joseph (1996), Lanyon (1984a), Lee Jones (2004), Lowen *et al.* (1996), Mobley (2002), Moermond & Denslow (1985), Monroe (1968), Morton (1977), Narosky & Salvador (1998), Oren & Parker (1997), de la Peña (1987, 1988), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson (1985, 1997), Robinson & Terborgh (1997), do Rosário (1996), Salaman (1994), Short (1975), Sick (1993, 1997), Skutch (1960, 1972, 1985), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thomas (1979b), Traylor (1977), Traylor & Fitzpatrick (1982), Tostain *et al.* (1992), Walther (2004), Warter (1965), Wetmore (1972), Willis (1980), Zimmer (1930).

Genus *MYIOZETETES* P. L. Sclater, 1859

335. **Rusty-margined Flycatcher**
Myiozetetes cayanensis

French: Tyran de Cayenne **Spanish**: Bienteveo Alicastaño
German: Rostschwingen-Maskentyrann

Taxonomy. [*Muscicapa*] *cayanensis* Linnaeus, 1766, Cayenne.
Morphological and behavioural evidence suggests genus most closely related to *Legatus*; nesting behaviour links with *Pitangus*. Molecular data indicate strong support for a clade consisting of present species and *M. similis* as sister-group to one formed by *M. granadensis* and *M. luteiventris*. South American races require closer scrutinty; birds from E Panama described as additional race, *harterti*, on basis of smaller size, but subsequently considered inseparable from *hellmayri*. Four subspecies currently recognized.
Subspecies and Distribution.
M. c. hellmayri Hartert & Goodson, 1917 - E Panama (E from Canal Zone), tropical N & W Colombia (W of E Andes), W Venezuela (Maracaibo Basin, and W slope of Andes from W Lara S to Táchira) and W Ecuador (S to El Oro and W Loja).
M. c. rufipennis Lawrence, 1869 - N Venezuela (N of R Orinoco), E Colombia E of E Andes (Norte de Santander S to W Caquetá and Vaupés) and E Ecuador.
M. c. cayanensis (Linnaeus, 1766) - S Venezuela (Amazonas, Bolívar, Delta Amacuro), the Guianas, N & C Brazil (R Negro E to Maranhão and Piauí, S to E Acre, Rondônia, Mato Grosso, Goiás and W Minas Gerais), SE Peru (Madre de Dios) and N Boliva (S to Cochabamba and N Santa Cruz).
M. c. erythropterus (Lafresnaye, 1853) - SE Brazil (S & E Minas Gerais, Rio de Janeiro).
Descriptive notes. 16·5-18 cm; 26 g. Nominate race has head mostly dark sooty or blackish-brown, large bright yellow to golden-orange coronal patch (mostly concealed), broad white supercilia confluent on forehead and nearly so on nape; upperparts plain brown to olive-brown; wings deep greyish-brown, dull olive margins on inner secondaries, narrow rusty or cinnamon-rufous edges of distal



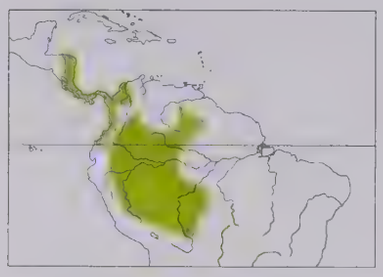
secondaries and proximal primaries, primaries with narrow paler rufous margins; tail dusky brownish with light olive edging; chin and throat white; underparts, including axillaries and underwing-coverts, bright yellow; iris brown; bill stubby, black; legs black. Differs from similar *M. similis* in having less dusky head, less olivaceous back. Sexes alike, female on average slightly smaller than male. Juvenile resembles adult, but lacks crown patch and has broader, more rusty-cinnamon margins on wing and tail feathers. Race *hellmayri* is very similar to nominate, but lighter and more olivaceous above, with less pronounced rufous margins on primaries; *rufipennis* has broader and more conspicuous rufous on wings (basal half of primaries on both webs) and tail, but birds in Orinoco Valley more like nominate; *erythropterus* is larger than nominate, also has more prominent rufous in wing. VOICE. Most common call a thin, whining, almost plaintive "peeeeeeeea" or "wheeeeee" 2-3 seconds long, sometimes repeated several times; various other vocalizations when excited, e.g. loud and emphatic "puuuureeeéét-éét-éét" or "too-eeéet", and quick rolling series of "keé-wit" "tis-u" or "chew-chewit" repeated numerous times and sometimes given in duet. Dawn song a repeated "fwee", sometimes with short couplet or additional note added.
Habitat. Shrubby areas and clearings, semi-open areas, cultivation, other disturbed habitat retaining some trees, also forest borders and gallery forest; also along oxbow lakes and river edges in Amazonia. More often near water and less common around habitations than *M. similis*, but where latter absent frequents more residential areas such as ranches, parks and gardens (usually staying farther from habitations compared with that species); in some areas the two species seem to replace each other. Mostly below 1000 m; sometimes to 1900 m and recorded rarely as high as 2100 m.
Food and Feeding. Insects, also fruits. Usually in pairs or small sociable groups; generally more retiring and less vocal than *M. similis*. Perches in the open at varying heights, sallying to the ground or foliage, or hawking insects from the air; often sallies over water. Takes small berries by hover-gleaning and quick hover-snatching.
Breeding. Breeding recorded in Mar-Aug in Venezuela (Hato Masaguaral, in Guárico); laying in Mar-Apr in Panama; in Colombia, juvenile and laying female in Jan in N Huila, nest-building observed Mar, Aug and Nov and fledglings by early Jun in Anchicayá Valley, nest-building early Jun in Valle, and nestlings in May in W Meta. Sometimes produces "prrrew-prrrew" wing noise that has been suggested as possible display behaviour; sometimes assumes erect posture, flaps wings, and reveals partially concealed crown patch when vocalizing excitedly. Bulky domed nest with side entrance, made of dried grass and small twigs, placed 2-4 m above ground in variety of usually conspicuous sites, often towards outside of dense brush, and wedged in crotch or with support built into base and sides of structure. Clutch 2-3 eggs; no information on incubation; fledging 17-21 days. In Panama, 37% of nests successful, with all recorded losses due to predation.
Movements. Not well known; numbers appear to fluctuate seasonally S of Orinoco, but not clear whether populations are resident or migrant; more information needed.
Status and Conservation. Not globally threatened. Fairly common to common. Usually less numerous than with *M. similis* in areas where the two are sympatric. Tolerant of converted habitats, and occurs in many national parks and other protected areas throughout its large range.
Bibliography. Ames (1971), Anon. (1998a), Bangs & Penard (1921), Best *et al.* (1993), Birdsley (2002), Bond *et al.* (1989), Cintra (1997), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Dyrcz (2002), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (1997, 2003), Hilty & Brown (1986), Lanyon (1984a), Lawrence (1869), Mamani (1998), Miller (1947, 1963), Mobley (2002), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Salaman (1994), Sibley & Ahlquist (1985c), Sick (1993, 1997), Skutch (1985), Smith, W.J. (2001), Stotz *et al.* (1996), Thomas (1979b), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Warter (1965), Wetmore (1972), Willis (1980).

336. **Social Flycatcher**

Myiozetetes similis

French: Tyran sociable **German**: Rotscheitel-Maskentyrann **Spanish**: Bienteveo Sociable
Other common names: Vermilion-crowned Flycatcher

Taxonomy. *Muscicapa similis* Spix, 1825, mouth of River Madeira, Brazil.
Morphological and behavioural evidence suggests genus most closely related to *Legatus*; nesting behaviour links with *Pitangus*. Molecular data support clade consisting of present species and *M. cayanensis* as sister-group to one formed by *M. granadensis* and *M. luteiventris*. Present species may be better split: race *grandis*, with restricted range, differs vocally from widespread nominate; N races *primulus*, *hesperis* and *texensis* may form a separate species. Proposed races *connivens* (Urubamba) and *fiedleri* (Ucayali) included in nominate. Seven subspecies recognized.
Subspecies and Distribution.
M. s. primulus van Rossem, 1930 - W Mexico (S Sonora S to N Sinaloa).
M. s. hesperis A. R. Phillips, 1966 - W Mexico (C Sinaloa and S Zacatecas E to SW Puebla, S at least to SE Oaxaca).
M. s. texensis (Giraud, 1841) - E & S Mexico (from SW Tamaulipas S through Yucatán Peninsula), Belize, much of Guatemala, El Salvador, Honduras, Nicaragua and Costa Rica (except SW).
M. s. columbianus Cabanis & Heine, 1859 - SW Costa Rica and Panama, N coast of Colombia (S from Caribbean lowlands through Magdalena Valley to Huila) and N Venezuela (E to Sucre, S to to N Amazonas and N Bolívar).
M. s. grandis Lawrence, 1871 - W Ecuador (S from W Esmeraldas) and extreme NW Peru (lowlands E of Andes and Pacific slope in Tumbes).
M. s. similis (Spix, 1825) - E Colombia E of E Andes (S from Norte de Santander), SE Venezuela (Amazonas, S Bolívar), French Guiana, E Ecuador, E & C Peru, Amazonian Brazil (except most drainages of R Tocantins and R Xingu) and N Boliva (S to Cochabamba and N Santa Cruz).
M. s. pallidiventris Pinto, 1935 - E Brazil (E Pará E to Paraíba, S to N Rio Grande do Sul), E Paraguay (W at least to Caaguazú) and NE Argentina (Misiones).
Descriptive notes. 16-18·5 cm; 24-27 g. Nominate race has head mostly dark grey to brownish-grey, large bright red to orangish-red coronal patch (mostly concealed), broad white supercilia confluent on forehead (where usually tinged greyish-white) and nearly connecting on nape, auriculars with fine paler shaft streaks; upperparts dull olive-green or brownish-olive, more greyish-olive on hindneck, uppertail-coverts greyish-brown or greyish-olive; wings deep greyish-brown, remiges with pale olivaceous edging, margins paler and more greyish-white to buffy white on inner secondaries, wing-coverts olive or brownish-olive with greyish-white margins (sometimes appearance of two faint wingbars); tail deep greyish-brown, rectrices with pale olive margins; chin and throat white or yellowish-white; underparts, including axillaries and underwing-coverts, bright yellow;



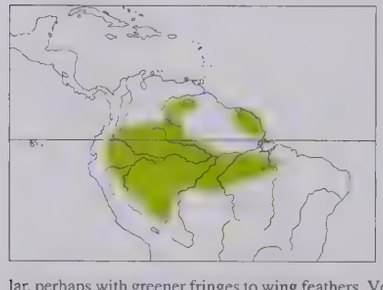
iris brown; bill rather small and stubby, black; legs black. Sexes alike, female on average slightly smaller than male. Juvenile resembles adult, but usually without coronal patch (if present, is very small and pale orange), more greyish-brown (not olivaceous brown) above, remiges and rectrices more broadly edged with rufous on both webs and terminally, and greater and median wing-coverts with buff-cinnamon margins. Races vary only slightly in plumage, mainly in tone of feather fringes on wing, and also tone of concealed coronal patch; *grandis* is larger than nominate, slightly brighter yellow below, and has wider and slightly paler wing-covert margins; *columbianus* said to average smaller than others, with lighter grey in crown, deeper and brighter underparts, paler terminal margins on wing-coverts. VOICE. Variety of loud, excited, generally strident calls; most common is a shrill and piercing "seeá", "tcheiit" or "see-yh!" scream; also various nasal or somewhat shrill, rapid twittering and bickering phrases, as "t-cheer-cheer-che-tiqueer" or "chiir t-chiir t-chirr"; also shrill note repeated several times, sometimes followed by longer and continuously repeated series, "seeu, seeu, see-u-chú", "sree, sree, sree si-si-chuhr", or shorter but still repeated "chirrrr" that probably represents a dawn song. Voice said to differ geographically, e.g. birds E of Andes (nominate race) giving chattered "ti-ti-ti-tíchew, chew" and a single "chew" or "chek", those W of Andes (*grandis*) give chattered "kree-kree-kree".
Habitat. Moist to humid and semi-arid semi-open lowland areas with scattered bushes and trees, shrubby clearings, second growth, forest and woodland canopy and borders, lake and river margins, shady gardens, pastures, cultivated regions, and residential areas; especially numerous near water in some areas. Mostly below 1000 m, but in smaller numbers to 1700 m and occasionally higher, especially when nesting.
Food and Feeding. Insects, also occasionally tadpoles; considerable quantities of small berries, arillate seeds, and other fruits also consumed. Most often in pairs; also in small, sociable family groups for short period after breeding season; large groups often congregate at fruiting trees; generally rather noisy and excitable. Perches, sometimes with partially cocked tail, in open spaces on top or outer edges of vegetation. Forages at varying heights, from ground level to the canopy of large trees, but usually at middle levels; hawks insects by long aerial sallies or in short sallies to vegetation; often drops to the ground to pursue insects; sometimes enters shallow water to catch tadpoles. Fruits taken from a perch or gleaned in quick hovering flight.
Breeding. Season in most areas thought to be rather protracted; recorded in Feb-Jun in Costa Rica and May-Jul in Venezuela (Hato Masaguaral, in Guárico); nest-building observed in Jan (Leticia), Mar (R Frío) and Apr (Santa Marta) in Colombia; laying in Mar-Apr in Panama; nests Aug-Jan in SE Peru; nests found in Oct and Nov in Argentina. Sometimes produces noisy wing-fluttering in flight, has been suggested as possible display behaviour. Bulky nest built by female, domed and with side entrance, made of dried grass, straw, weed stems, small twigs, and often bits of cotton, paper and strands of plastic from grain bags; placed in variety of conspicuous sites, including various man-made structures and sometimes over water, but usually in fork of branch at middle to upper levels (c. 2-15 m) in tree or dense, often thorny bush; occasionally uses nest of another bird as foundation, or fills existing cavity with some nesting material; frequently nests in close proximity to nest of hymenopteran (bee, wasp, or stinging ant), and often in same tree or bush as one or more other tyrannids (especially *Pitangus*, *M. cayanensis*, *Fluvicola*, *Tolmomyias*, etc.). Clutch 2-4 eggs; incubation by female, period 15-16 days; fledging 17-21 days. In Panama, 28% of nests successful, with 68% lost to predation and 4% to other causes. Single brood raised annually, but pair may attempt up to 5 nests/season due to predation.
Movements. Not well known; probably resident in many areas and at least partially migratory in others. In Venezuela, for example, thought to be resident in most of C & W; probably at least partially migratory in *llanos*, being absent during rainy season (c. Jun-Oct), but still unclear whether these populations move long or short distances; scarce, absent or seasonal (present about Apr-Nov) in much of E Venezuela; variable numbers occur in NW Amazonas, where more recorded in Jun than in Dec-Feb. Populations breeding in SE Brazil (Rio de Janeiro) said to be migratory.
Status and Conservation. Not globally threatened. Common to very common in most of range. Thrives in variety of semi-open habitats, including those that have been converted and those in agricultural and residential areas. Occurs in numerous protected areas within its large range.
Bibliography. Ames (1971), Anon. (1998a), Berlepsch & Stolzmann (1906), Binford (1989), Birdsley (2002), Brooks *et al.* (1993), Cintra (1997), Clements & Shany (2001), Cory & Hellmayr (1927), Darlington (1931), Davies *et al.* (1994), Dunajewski (1939), Dyrcz (2002), Fitzpatrick (1980a, 1980c, 1981, 1985a), Guix (1995), Haffer (1975), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Lanyon (1984a), Lee Jones (2004), Lowen *et al.* (1996), Mobley (2002), Monroe (1968), Narosky & Salvador (1998), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson (1997), Robinson & Terborgh (1997), Rodrigues & Santos (2000), do Rosário (1996), Rowley (1984), Sibley & Ahlquist (1985c), Sick (1993, 1997), Skutch (1985), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thomas (1979b), Todd & Carriker (1922), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Warter (1965), Wetmore (1972), Williams & Tobias (1994), Willis (1980), Zimmer (1937c).

337. **Grey-capped Flycatcher**

Myiozetetes granadensis

French: Tyran à tête grise **German**: Graukappen-Maskentyrann **Spanish**: Bienteveo Cabecigrís

Taxonomy. *Myiozetetes granadensis* Lawrence, 1862, Panama.
Morphological and behavioural evidence suggests genus most closely related to *Legatus*; nesting behaviour links with *Pitangus*. Molecular data indicate strong support for a clade consisting of present species and *M. luteiventris* as sister-group to one formed by *M. cayanensis* and *M. similis*. Race *occidentalis* possibly better merged with nominate; further study required. Three subspecies currently recognized.
Subspecies and Distribution.
M. g. granadensis Lawrence, 1862 - E Honduras, Nicaragua and Costa Rica S to CE Panama.
M. g. occidentalis J. T. Zimmer, 1937 - E Panama (Darién), N & W Colombia (W of Andes) and NW Ecuador (S to N Manabí and S Pichincha).
M. g. obscurior Todd, 1925 - C & E Colombia (lower Magdalena Valley S to SE side of Serranía San Lucas, S from W Meta and Vaupés, and widely E of E Andes) and SE Venezuela (C & S Amazonas, W Bolívar) S to E Ecuador, E Peru (E of Andes), W Brazil (E to N Roraima, W Amazonas and Rondônia) and N Bolivia (S to Cochabamba and N Santa Cruz).
Descriptive notes. 16-18 cm; 28-30 g. Has crown and nape grey, semi-concealed orange-yellow or reddish-orange coronal patch; white forehead extending into rather short, narrow white supercilium to just past eye, dusky loral, suborbital and auricular regions; upperparts mostly olive-green, uppertail-



coverts dusky or dark olive with paler edging; wings dusky greyish-brown, wing-coverts with olive margins, lesser coverts pale olive-green, remiges with light yellowish-olive or cinnamon margins; tail dusky, rectrices with light olive margins; chin and throat white or yellowish-white; underparts, including axillaries and underwing-coverts, bright yellow, slight olive tinge on chest side; iris pale brownish-grey; bill rather short, black; legs black. Sexes similar, female sometimes with coronal patch lacking or considerably reduced. Juvenile is essentially like adult, but with greyish-olive tinge on crown and nape, broader and more tawny margins on both webs of rectrices, slightly paler yellow underparts, light tawny-brown or cinnamon edging on wing-coverts and secondaries, paler and more yellowish margins on tertials. Race *obscurior* larger and somewhat darker; *occidentalis* slightly smaller than previous. Voice. Sharp, dry, emphatic, and often incessantly repeated nasal "kip", "bip" or "wic" notes and longer "kip-kee-kew" or "kip-kip-kip-it" series with subtle variations; also harsh, strident, aggressive-sounding staccato notes, "kurr keer ch'beer, k'keer keer jeer k'beer", in interactions; also said to give loud, hoarse, and variously repeated dawn song "kip kip kip-keeuw-kreh" (W of Andes) 2-3 seconds long, and shorter (1-2 seconds) but faster "kip-kip-kip-kip-kip-kip, ke-ke-kree-yí" phrase.
Habitat. Agricultural areas with scattered trees, semi-open and shrubby clearings, humid second growth, overgrown forest borders, occasionally near houses; numerous near standing water, and along rivers and streams. Seems to prefer more humid habitat than congeners. Mostly to 1100 m, but recorded to 1650 m in Costa Rica (along Pacific slope of Cordillera de Talamanca); in small numbers regularly to just over 1200 m in Panama (W Chiriquí) and to 1300 m in Ecuador (Mindo).
Food and Feeding. Insects; considerable quantities of berries and arillate seeds also consumed. Usually in pairs or small, sometimes noisy, family groups, but often alone; sometimes in larger groups of up to a dozen individuals for a period following breeding season. Seems to prefer lower perches, but also perches on top of taller trees. Sallies short to medium distances, sometimes longer, in pursuit of flying insects; occasionally sallies to foliage to glean insects.
Breeding. Breeds Feb-Jun, occasionally to Aug, in Costa Rica and during Feb-May dry season in Panama; nest found in Mar in Colombia (Buenaventura); nests Sept-Jan in SE Peru. Nest a bulky, globular or domed structure with side entrance, composed primarily of weed stems, straw and dried grasses, placed 1-18 m (usually 1·5-8 m) above ground in tree or bush; often nests with congener in same tree or bush. Clutch 2-3 eggs, sometimes 4. No other information.
Movements. Not well known. Probably mainly resident.
Status and Conservation. Not globally threatened. Fairly common to common. Has relatively extensive range; possible occurrence also in NW Peru doubted, as single 1877 specimen from Tumbes may have been confused with *M. similis*, and no subsequent reports. Thrives in secondary habitats and in agricultural and residential areas, and occurs in several national parks and other protected areas throughout its range.
Bibliography. Ames (1971), Anon. (1998a), Birdsley (2002), Blake (1962), Clements & Shany (2001), Cory & Hellmayr (1927), Fitzpatrick (1980a), Haffer (1975), Hilty (2003), Hilty & Brown (1986), Lanyon (1984a), Meyer de Schauensee (1982), Moermond & Denslow (1985), Monroe (1968), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Robinson (1997), Robinson & Terborgh (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Skutch (1960, 1985), Slud (1960, 1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Traylor (1977), Traylor & Fitzpatrick (1982), Warter (1965), Wetmore (1972), Willard *et al.* (1991), Zimmer (1937c).

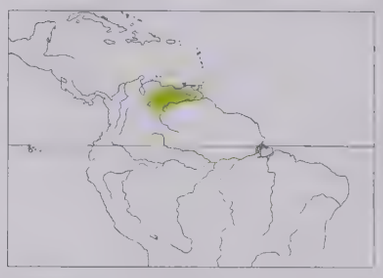
338. **Dusky-chested Flycatcher**

Myiozetetes luteiventris

French: Tyran à gorge rayée **Spanish**: Bienteveo Pechioscuro
German: Strichelbrust-Maskentyrann
Other common names: Orange-vented Flycatcher

Taxonomy. *Elaenia luteiventris* P. L. Sclater, 1858, River Napo, Ecuador.
Morphological and behavioural evidence suggests genus most closely related to *Legatus*; nesting behaviour links with *Pitangus*. Taxonomic history of this species somewhat turbulent; orginally described within genus *Elaenia*, and subsequently transferred back and forth between current genus and *Tyrannopsis*, largely because of its smaller size and peculiar coloration compared with present congeners. Molecular data indicate strong support for a clade consisting of present species and *M. granadensis* as sister-group to one formed by *M. cayanensis* and *M. similis*. Validity of race *septentrionalis* uncertain. Two subspecies recognized.
Subspecies and Distribution.
M. l. septentrionalis Blake, 1961 - E Surinam, French Guiana and adjacent NE Brazil (Amapá).
M. l. luteiventris (P. L. Sclater, 1858) - E Ecuador and SE Colombia (S from Putumayo and Vaupés) E to SE Venezuela (S Bolívar), S to Amazonian Brazil (E to E Pará and W Maranhão, S to Rondônia and N Mato Grosso), E Peru (Loreto and Madre de Dios, probably also elsewhere) and extreme NW Bolivia (Pando, N La Paz).

Descriptive notes. 14-15 cm; 16·5 g. Plumage is dark olive-brown above, head slightly more greyish-brown and with some faint greyish streaking at side, semi-concealed yellow-orange coronal patch; crown feathers appear rather long; wing feathers variably edged rufous; throat whitish with faint dusky streaking; underparts bright yellow, chest and upper breast with strong olive shading or flammulation and smudgy dark olive streaking; bare parts black. Sexes similar, but female lacks coronal patch or may have patch reduced to some pale yellow feather edges. Juvenile undescribed. Race *septentrionalis* is very similar, perhaps with greener fringes to wing feathers. Voice. Most frequent call a nasal, cat-like "meeow" or softer "neea"; when excited, fast nasal "nyeeuw-nyeeuw, keep-kít" or "neea-ne-wít", sometimes presented as jumbled duet, or simply shortened and often repeated "keeuw" or "nyeeuw" somewhat like voice of *M. granadensis* but more nasal and whining.
Habitat. Shrubby forest borders, clearings with scattered bushes or trees, openings within forest created by treefalls, canopy of *terra firme* and *várzea*, and edges of lakes and rivers. To 600 m.
Food and Feeding. Insects and fruits. Usually in pairs or small groups, sometimes singly; mostly independent of mixed-species flocks. Perches on exposed twigs or on top of vegetation, usually 3-20 m up at edge of tall trees or canopy; erect posture, sometimes with tail cocked; often flicks tail and jerks head when calling or alighting. Sallies short distances or hover-gleans insects from foliage, but occasionally hawks flying insects; regularly visits fruiting trees and shrubs, often mingling with other species, to hover-glean or perch-glean small berries, often at much lower levels.
Breeding. Poorly known. Male in breeding condition in May in Colombia (Vaupés). One nest described: large, bulky, domed structure of grasses, some longer strands of grass hanging below entrance on side, placed not more than 1 m from top of large tree at forest edge. No other information.
Movements. Poorly known; considered to wander rather widely and may be partially migratory.
Status and Conservation. Not globally threatened. Rare to locally uncommon, but perhaps often overlooked; possibly more widespread and more numerous than previously realized. Not well known. Occurs in several national parks and other protected areas throughout its relatively large range, e.g. Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, Tapajós National Park, in Brazil. No known threats, as most of its habitat is still in reasonably pristine condition.
Bibliography. Ames (1971), Anon. (1998a), Bates & Parker (1998), Birdsley (2002), Blake (1961), Clements & Shany (2001), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1984a), Meyer de Schauensee (1966, 1982), Meyer de Schauensee & Phelps (1978), Novaes (1978a), Oren & Parker (1997), Parker & Remsen (1987), Peres & Whittaker (1991), Remsen (1977), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Robinson *et al.* (1988), Schulenberg *et al.* (2001), Sclater (1871a), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Warter (1965), Zimmer (1937c).



Genus *PHELPSIA* W. E. Lanyon, 1984

339. **White-bearded Flycatcher**

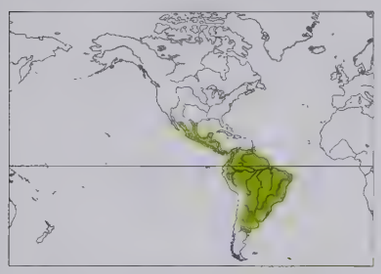
Phelpsia inornata

French: Tyran des llanos **Spanish**: Bienteveo Barbiblanco
German: Schwarzscheitel-Maskentyrann

Taxonomy. *Myiozetetes inornatus* Lawrence, 1869, Valencia, Carabobo, Venezuela.
Affinities uncertain. In past variously placed in genera *Myiozetetes* and *Conopias*, but differs significantly in syringeal morphology and nest architecture. A single syringeal character suggests that it is most closely related to *Pitangus* and *Philohydor*; recent molecular data indicate that it forms a clade with latter (both build cup-shaped nests, details of which not particularly similar), with no apparent affinity to *Pitangus*. Further research and additional molecular data required. Monotypic.
Distribution. N & C Venezuela, from Carabobo, Miranda and Cojedes E to NE Anzoátegui and Delta Amacuro, S to Apure and N Bolívar; possibly also adjacent NE Colombia.

Descriptive notes. 16·5-18 cm; 29 g. Has crown and side of head brownish-black, long white supercilia confluent on nape; upperparts olive-brown; wings olive-brown, narrow yellowish margins on primaries; throat white, prominent and puffy-looking; underparts bright yellow; iris dark; bill very short, stubby, black; legs blackish. Distinguished from similar *Myiozetetes* species by especially puffy-headed appearance, puffy white throat, comparatively stubby bill. Sexes alike. Juvenile undescribed. Voice. Most common call a load, sharp, rising "churup" or "cheedurit", also repeatedly as alarm; duet call a staccato "chéé'ter" given repeatedly, up to 12 couplets by each partner, during territorial challenges, may also be heard a few times early in day.
Habitat. Pastures with scattered trees, small groves of woodland in open to semi-open *llanos*, lighter woodland borders, gallery forest, and trees near ranch buildings. Typically below 500 m.
Food and Feeding. Insects; small fruits taken infrequently. Usually observed in pairs, occasionally in small family groups; fairly quiet and reserved, perching inconspicuously at various heights. Often sallies from perch to the ground in pursuit of prey; also sallies to taller grass and low vegetation; occasionally hawks flying insects or gleans items from foliage.
Breeding. Mar-Aug. Non-breeding helpers sometimes assist nesting pair. During territorial challenges, displays with excited bowing and wing-flutters, calling loudly, and perching higher and out in the open. Nest a nicely formed open cup, composed of an array of fine twigs, petioles, leaf tendrils, rootlets, dried leaf skeletons, and occasionally feathers and horsehair, materials sometimes bound together with spider silk, often covered with bits of lichen (making nest quite cryptic); typically placed fairly high in fork on horizontal tree branch. Clutch 2 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common or common. Very common at Hato Los Indios (R Capanaparo), in SE Apure. Appears to be reasonably adaptable; occurs in agricultural and residential areas.
Bibliography. Aveledo (1986), Berlepsch (1907), Berlepsch & Hartert (1902), Birdsley (2002), Cherrie (1916), Hilty (2003), Lanyon (1984a), Lawrence (1869), Meyer de Schauensee (1966, 1982), Mobley (2002), Phelps & Phelps (1963), Ridgely & Tudor (1994), Rojas *et al.* (1997), Sclater (1871a, 1888), Skutch (1985), Stotz *et al.* (1996), Thomas (1979a), Traylor (1977), Varty *et al.* (1986), Wetmore (1939).

Genus *PITANGUS* Swainson, 1826



340. **Great Kiskadee**

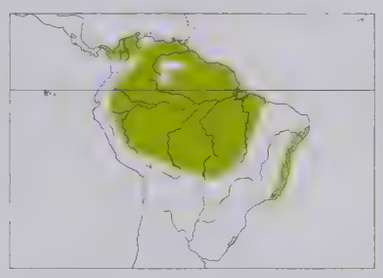
Pitangus sulphuratus

French: Tyran quiquivi **German**: Schwefelmaskentyrann **Spanish**: Bienteveo Común

Other common names: Greater Kiskadee, Kiskadee Flycatcher

Taxonomy. [*Lanius*] *sulphuratus* Linnaeus, 1766, Cayenne.
Affinities uncertain; may be closely related to *Myiozetetes*, given numerous similarities in nesting behaviour. Populations in Amazonia, including slightly larger birds of SE Colombia and the Guianas, may be better represented as a single race (nominate), owing to lack of clear distinctions and to the existence of gradual clines of increasing wing length N & S of Amazon that are not correlated with any observed colour differences. Formal revision, including genetic survey, is necessary in order to determine the most appropriate taxonomic designations. Ten subspecies currently recognized.
Subspecies and Distribution.
P. s. texanus van Rossem, 1940 - extreme S USA (lower Rio Grande) and E Mexico (S to S Veracruz).
P. s. derbianus (Kaup, 1852) - W Mexico (Sonora S to Isthmus of Tehuántepec).
P. s. guatimalensis (Lafresnaye, 1852) - SE Mexico (S Veracruz, E Oaxaca, Chiapas, Tabasco, and Yucatán Peninsula), Guatemala, Belize and El Salvador S to C Panama.
P. s. rufipennis (Lafresnaye, 1851) - N Colombia (Caribbean coast and lower Magdalena Valley), N & C Venezuela (E to W Sucre and Monagas, S to N Amazonas and N Bolívar).
P. s. caucensis Chapman, 1914 - W & S Colombia (SW Bolívar, R Cauca and upper R Magdalena).
P. s. trinitatis Hellmayr, 1906 - E Colombia (R Meta), S & E Venezuela (Amazonas, and E Sucre S to Orinoco Delta and E Bolívar) and NW Brazil (R Surumú and R Cotinga); also Patos I and Trinidad.
P. s. sulphuratus (Linnaeus, 1766) - the Guianas, N Brazil (S to Amazon, E to Amapá and Marajó I), and E of Andes from SE Colombia and E Ecuador S to SE Peru.
P. s. maximiliani (Cabanis & Heine, 1859) - E & S Brazil (Maranhão and Piauí S to Mato Grosso, Goiás and Santa Catarina), N Bolivia (Beni) and Paraguay.
P. s. bolivianus (Lafresnaye, 1852) - E Bolivia (Cochabamba S to Tarija).
P. s. argentinus Todd, 1952 - Argentina (S to E Mendoza, Córdoba and Río Negro), E Paraguay, extreme SE Brazil (Rio Grande do Sul) and Uruguay.
Introduced in Bermuda (*trinitatis*).

Descriptive notes. 20·5-23·5 cm; 53-68 g. Has blackish crown, semi-concealed yellow coronal patch; side of head blackish, broad white supercilia extending from forehead to nape (where confluent or nearly so); upperparts olive-brown to brownish-olive, uppertail-coverts somewhat suffused and margined with cinnamon-rufous; wings more or less deep greyish-brown to olive-brown, remiges and wing-coverts with cinnamon-rufous bases and margins, remiges also with dusky tips; tail greyish-brown or dusky, fairly broad cinnamon to rufous edging on outer webs and extensive cinnamon-rufous edging on inner webs; chin, throat and malar region prominently white, underparts bright yellow; iris dark; bill heavy, straight, relatively long, black, slightly more brownish on lower part of lower mandible; legs blackish. Sexes alike. Juvenile is similar to adult, but lacks yellow on crown, has broader, paler cinnamon-rufous margins on wing-coverts and inner secondaries. Races vary mainly in size (clinal variation) and colour tones, nominate being more or less intermediate between those to N & S but tending to be generally darker brown above and to have slightly smaller bill; *texanus* is large, rather dark, margins of wing feathers deep rufous; *derbianus* and *guatimalensis* are slightly paler overall than races farther S; *rufipennis* tends to be smaller, has upperparts more rufous-brown, extensive rufous in wings and tail; *trinitatis* is most like previous, but with much narrower rufous margins on wing-coverts, less rufous on remiges, much less rufous on rectrices (narrower margin on outer web, rufous inner third of inner web); *caucensis* is similar to previous; *maximiliani* has somewhat heavier bill than nominate, more white on forehead, less orange in coronal patch, paler underparts; *bolivianus* is larger and longer-winged than nominate, has heavier bill, paler brown upperparts, very narrow and lighter rufous margins on primaries; *argentinus* is similar to last. Voice. Quite vocal and rather noisy; variety of loud calls, the most common "kiss-ka-dee", with much variation in number of "dee" notes at end of series; also loud "k-reah" or "kih-kerrr"; dawn song described as raucous "kyah k-yah zzk-zzik ky-ar" or "beeeww-biew-prrrr-beeeww", repeated, often including sonorous "prrr" rattle, and with some longer variations; also softer churring notes around nest, and shrill "eeek" when mobbing predators.
Habitat. Wide variety of habitats, including busy residential and even urbanized areas, semi-open cultivated areas, open grassland and pasture with scattered trees and bushes; also second growth, dry forest edges, gallery forest margins, larger clearings within and edges of primary forest (especially near water). Mostly below 1600 m, occasionally higher.
Food and Feeding. Diet extremely variable, mainly insects and fruit, but also small vertebrates, including nestlings of smaller birds, fish, lizards, snakes, frogs, tadpoles and even mice, as well as earthworms and spiders. Usually alone or in pairs, occasionally in small family groups. Regularly perches in conspicuous place, often at lower levels and in open. Generally hawks insects from a variety of low and open perches, often dropping to the ground; fruits taken by hover-gleaning or perch-gleaning. Fish caught by diving, in manner much like that of a kingfisher (Alcedinidae).
Breeding. Feb-Jun, occasionally Oct, in Mexico; in Colombia, nestlings in Feb and Apr-May (Santa Marta), nest-building in Mar (Leticia) and May (NE Meta); breeds Mar-Sept in Venezuela; mainly Feb-May, and recorded in all months except Sept, in Trinidad; Oct-Feb in Argentina; up to three broods in a season. Partners often raise crest and give wing-shivering display when vocalizing to one another. Nest built by both sexes, a large and bulky domed structure with side entrance, composed of great variety of materials, primarily differently sized grasses, weed stems, straw and small twigs, often incorporating mosses, lichen, string, rope, bits of plastic, rags, cotton, paper, other refuse, and sometimes whole nests of smaller birds; often long strands of vegetation hanging below entrance; for seven nests in Argentina, mean height 28 cm, width 21·6 cm, depth 25·6 cm, entrance diameter 8·1 cm; placed prominently at variable height (1-15 m) and in wide range of sites, including tree limb, bush, cactus, artificial structure (e.g. telephone pole, windmill tower, roof overhang); occasionally built in cavity, and sometimes in close proximity to nest of hymentopteran (bee, wasp or ant); completely tolerant of other birds nesting close by, often nests close to *Myiozetetes* species, but very aggressive towards potential nest predators. Clutch 3-4 eggs, sometimes 5 in S of range; sometimes lays in open cup, usually before dome of nest completed; incubation by female, period 16-17 days; chicks fed by both sexes, fledging period 17-18 days, sometimes to 21 days (uncertain report of 15 days). Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Not well known; thought to be resident in most of range. Apparently leaves higher elevations and colder parts of S Brazil in austral winter; movement more apparent in Argentina, where a bird ringed in Santiago del Estero was recaptured in Jan in Santa Catarina (SE Brazil), c. 2000 km to E; more research necessary to determine seasonal movement patterns. Vagrants recorded in several areas, including Baja California and N & C Chile; accidental in Falkland Is.
Status and Conservation. Not globally threatened. Common to very common. Estimated global population c. 20,000,000 individuals. Has apparently increased in both range and abundance as a result of previously closed forest being opened up through various human activities; has also benefited from results of water irrigation, which has brought vegetation to semi-arid areas. Reasons for this species' absence from regions W of Andes are unclear.
Bibliography. Ames (1971), Anon. (1998a), Babarskas *et al.* (2003), Baicich & Harrison (1997), Barrows (1883), Bent (1942), Binford (1989), Birdsley (2002), Brooks *et al.* (1993), Brush & Fitzpatrick (2002), Cabanis & Heine (1859-1860), Canevari *et al.* (1991), Cintra (1997), Clements & Shany (2001), Collins *et al.* (1990), Contreras (1997), Cory & Hellmayr (1927), Davis (1941), Di Giacomo (2004), Ferreira de Vasconcelos (2004), ffrench (1991), Fitzpatrick (1980a, 1980c, 1981, 1985a), Fjeldså & Krabbe (1990), Haffer (1975), Haffer & Fitzpatrick (1985), Harris (1998), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hayes & Samad (2002), Hellmayr (1906a), Henderson (2002), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Johnson (1967), Kaufman (1996), Klimaitis & Moschione (1987), Lago-Paiva (1996), Lanyon (1984a), Leveque (1979), Lever (1987), Llambías *et al.* (2001), Longo *et al.* (2000), Lowen *et al.* (1996), Maragliano & Montalti (1995), Mason (1985), Miserendino (1998), Mobley (2002), Narosky & Salvador (1998), Oren & Parker (1997), de la Peña (1987, 1988, 1995), Price *et al.* (1995), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson (1997), Robinson & Terborgh (1997), do Rosário (1996), van Rossem (1940), Rowley (1984), Short (1975), Sibley & Ahlquist (1985c), Sick (1993, 1997), Skutch (1985), Slud (1964), Smith (1962), Stiles & Skutch (1989), Stotz *et al.* (1996), Thomas (1979a), Todd (1952), Todd & Carriker (1922), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Warter (1965), Wetmore (1972), Zimmer (1937c).



Genus *PHILOHYDOR* W. E. Lanyon, 1984

341. **Lesser Kiskadee**

Philohydor lictor

French: Tyran licteur **German**: Liktormaskentyrann **Spanish**: Bienteveo Chico

Taxonomy. *L[anius] Lictor* M. H. K. Lichtenstein, 1823, Belém, east Pará, Brazil.
Long considered close relative of *Pitangus*; on basis of a single syringeal character, suggested these two form a clade; substantial differences in morphology and behaviour, as well as molecular data, however, suggest otherwise. Molecular data indicate possible close relationship with *Phelpsia*, but additional evidence required in order to test this hypothesis. Two subspecies recognized.
Subspecies and Distribution.
P. l. panamensis Bangs & T. E. Penard, 1918 - E Panama (E from Canal Zone) and Caribbean coast of Colombia (Atrato E to Santa Marta and lower R Magdalena).
P. l. lictor (M. H. K. Lichtenstein, 1823) - Venezuela and the Guianas S to E Colombia, E Ecuador and E Peru, Amazonian & E Brazil (E to Amapá, Maranhão and W Piauí, S to Goiás and N Mato Grosso do Sul, and from Pernambuco S to Rio de Janeiro) and N Bolivia (S to Cochabamba and N Santa Cruz).

Descriptive notes. 15-18 cm; 25 g. Has black or sooty crown, large bright yellow coronal patch (semi-concealed), conspicuous white supercilia confluent or nearly so on nape, black or sooty head side with some greyish tinge on lores; upperparts mostly plain olive, uppertail-coverts greyish-brown or dark olive; wings deep greyish-brown with paler margins, remiges (and sometimes greater wing-coverts) with pale cinnamon or rufous edging; tail dark greyish-brown, central rectrices with cinnamon or rusty margins, lateral feathers edged paler greyish-brown, inner webs of all rectrices with narrow (broader basally) pale cinnamon margins; chin, throat and malar region white; underparts, including axillaries and underwing-coverts, bright yellow; iris dark; bill long, slender, blackish; legs black or blackish-brown. Distinguished from similar *Myiozetetes* species and *Pitangus* by smaller size, more slender proportions, also more sedate behavior and very different vocalizations. Sexes alike, female slightly smaller than male. Juvenile is similar to adult, but nape paler, crown with just a little or no yellow, upperparts more brownish-olive, rufous margins on wings and tail more prominent, underparts paler yellow. Race *panamensis* is decidedly smaller than nominate. Voice. Calls a vigorous, buzzy, rather nasal "dzay" or "dzweey", or more prolonged "dzay-dzwey-dwzee-zwee" with first note strongest and rising slightly; also "keekzi-deeée", "queé-be" and "dree, dear-wrr"; partners also give chattery "ca-déde" in greeting.
Habitat. Shrubby vegetation, low trees, snags and stumps near open water or marshy, shrubby pasture, especially along margins of lakes, ponds, slow-moving rivers, oxbow lakes; sometimes mangrove borders and wooded lagoons. Mainly below c. 500 m; recorded to 1300 m in Venezuela (Lara).
Food and Feeding. Insects. Usually in pairs, occasionally alone or in small groups of 3-4; most often perches at lower levels, usually not higher than c. 3 m, above ground or open water. Sallies to vegetation or surface of standing water, occasionally dropping to ground, in pursuit of prey.
Breeding. Two nests found in Jun (Caquetá) and two males in breeding condition in Jul (César) in Colombia; breeds Jun-Oct in Venezuela (W Apure); Oct-Jan in SE Peru. Excited wing-fluttering and raising of crown feathers by partners when greeting. Nest an open saucer or cup-shaped structure composed of rather coarse material, including small twigs and grasses, lined with finer materials such as rootlets, leaves and grass, generally placed on a stump or low bush, often over water; some suggestion, from limited observations, that side walls sometimes built up in less sheltered placements, but this questionable. Clutch 2-3 eggs. Family groups often roost side by side, touching one another. No other information.
Movements. Probably resident throughout range. One report of possible vagrant in Argentina (N Buenos Aires) may be erroneous, and confirmation required.
Status and Conservation. Not globally threatened. Fairly common. Occurs in many national parks and other protected areas throughout its relatively large range. Much of this species' habitat within its area of distribution remains in pristine or near-pristine condition.

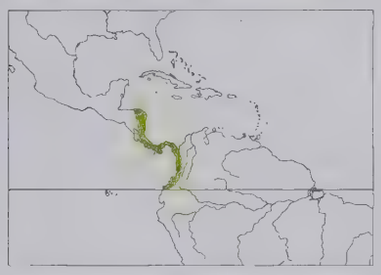
PLATE 41

inches 3

cm 8



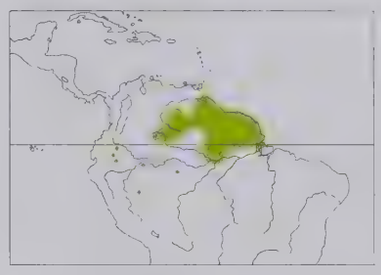
Genus *CONOPIAS* Cabanis & Heine, 1859

342. White-ringed Flycatcher

Conopias albovittatus

French: Tyran diadème **German**: Weißnacken-Maskentyrann **Spanish**: Bienteveo del Chocó

Taxonomy. *Pitangus albovittatus* Lawrence, 1862, Isthmus of Panama.
Has been hypothesized, on basis of hole-nesting behaviour, that genus may be most closely related to *Myiodynastes*, with this clade basal to a "*Tyrannus* group" that also includes *Megarynchus*, *Tyrannopsis*, *Empidonomus* and *Griseotyrannus*; molecular-sequence data, however, do not support an affinity between these two genera, but strongly suggest that present genus is part of that group to the exclusion of *Myiodynastes*. This species was formerly placed with *C. parvus* in a separate genus, *Coryphotriccus*, on grounds mainly of slightly larger bill and presence of a coronal patch, but syringeal morphology is similar to that of present genus. The two are sometimes considered conspecific, but differ in plumage and, especially, voice; furthermore, molecular-sequence data indicate substantial divergence between them, but also that they are closely related and represent a sister-group to a clade consisting of *C. cinchoneti* and *C. trivirgatus*. Validity of race *distinctus* questionable; closer study required. Two subspecies currently recognized.
Subspecies and Distribution.
C. a. distinctus (Ridgway, 1908) - E Honduras, Nicaragua, Costa Rica and W Panama.
C. a. albovittatus (Lawrence, 1862) - E Panama (E from Canal Zone), W Colombia (Chocó S to Nariño) and NW Ecuador (Esmeraldas, NW Pichincha and adjacent SW Imbabura).



Descriptive notes. 15-16·5 cm; 24 g. Nominate race has crown black to dark sooty brownish, large lemon-yellow to canary-yellow coronal patch (mostly concealed); prominent white supercilia meeting on forehead, broader at rear and confluent (or very nearly so) on nape; loral, suborbital, postocular and auricular regions black to dark sooty brownish, fine whitish shaft streaks in suborbital area and on anterior auriculars; upperparts largely greyish-olive-green to dark olive or olive-brown; wings dusky, browner than upperparts, narrow whitish or pale yellowish-white margins on secondaries and tertials, pale greyish-brown or olive edging on wing-coverts, less prominent darker greyish-brown margins on primaries; tail feathers dark greyish-brown with lighter grey-brown or olive margins; chin, throat and malar area white, underparts bright canary-yellow, axillaries and underwing-coverts as underparts; iris blackish; bill rather long, black; legs blackish. Distinguished from very similar *C. parvus* by distinctive white throat. Sexes alike, female on average smaller than male. Juvenile is similar to adult, but with more brownish upperparts, rusty barring on crown, no yellow coronal patch, wing-coverts and rump feathers with cinnamon margins, more buffy yellow edging on tertials. Race *distinctus* is said to be larger than nominate, more greyish-olive above, paler yellow below, with more extensive blackish area on side of head. Voice. Call very distinctive, commences with a long note, followed by rapid, rattling or whirring, repetitive trill, "tre-r-r-r-r, tre-r-r-r-r...", "kree-ee-ee-eer", or short, slightly nasal and descending "wheeerr" whistle followed by rattling "qua-tre-e-e-e-e-e-e", "wheeereeeeee-e-e-e" or "wheeeurrrrr-rreek" that rises in pitch and may slow near end; also gives prolonged, relatively higher-pitched, petulant trill that slows and ends with several discrete notes. Frequent bill-snapping during flight reported.
Habitat. Canopy and borders of humid forest; occasionally ventures out into clearings with tall trees next to mature forest, also in taller trees along waterways. Mostly below 1000 m, but regularly to 1350 m in Panama (Cerro Pirre, in Darién).
Food and Feeding. Insects and spiders; some berries also taken. Alone, in pairs, or in small groups of up to five individuals; occasionally accompanies mixed-species flocks. Generally perches at higher levels in canopy, often directly on top of crown foliage or on exposed twig, scanning leaves and branches below; sallies among foliage, flits actively about the vegetation.
Breeding. Mar-Jun in Costa Rica. Nest c. 10-15 m up in old woodpecker (Picidae) hole, natural tree hole or crevice, or niche in bromeliad cluster; no other details. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Details unknown; wanders to some degree, but probably resident in most areas.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in Río Negro Jaguar Reserve, in Costa Rica. In Ecuador, widespread in Esmeraldas, numerous NW of Alto Tombo, and common E of Muisne, at Bilsa, and at Playa de Oro; occurs in Cerro Blanco Forest Reserve. Probably tolerant of some forest degradation, as it is found in second growth and in trees in clearings. Field studies of this poorly known species needed.
Bibliography. Anon. (1998a), Birdsley (2002), Cory & Hellmayr (1927), Hilty & Brown (1986), Howell & Webb (1995a), Jahn & Mena (2002i), Lanyon (1984a), Mobley (2002), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Salaman (1994), Skutch (1972), Slud (1960, 1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

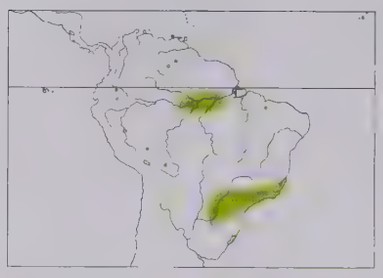
343. Yellow-throated Flycatcher

Conopias parvus

French: Tyran de Pelzeln **German**: Weißring-Maskentyrann **Spanish**: Bienteveo Guayanés
Other common names: Yellow-crowned Flycatcher

Taxonomy. *Pitangus parvus* Pelzeln, 1868, Marabitanas, Rio Negro, Brazil.
Has been hypothesized, on basis of hole-nesting behaviour, that genus may be most closely related to *Myiodynastes*, with this clade basal to a "*Tyrannus* group" that also includes *Megarynchus*, *Tyrannopsis*, *Empidonomus* and *Griseotyrannus*; molecular-sequence data, however, do not support an affinity between these two genera, but strongly suggest that present genus is part of that group to the exclusion of *Myiodynastes*. This species was formerly placed with *C. albovittatus* in a separate genus, *Coryphotriccus*, on grounds mainly of slightly larger bill and presence of a coronal patch, but syringeal morphology is similar to that of present genus. The two are sometimes considered conspecific, but differ in plumage and, especially, voice; furthermore, molecular-sequence data indicate substantial divergence between them, but also that they are closely related and represent a sister-group to a clade consisting of *C. cinchoneti* and *C. trivirgatus*. Monotypic.
Distribution. S & E Venezuela (W Amazonas E locally to E Bolívar), extreme E Colombia (E Vaupés, Guainía), very locally NE Ecuador (E Sucumbíos, extreme SE Pastaza), extreme NE Peru (N Loreto); also the Guianas, and Brazil primarily N of Amazon and R Solimões (locally from N Roraima and upper R Negro S to lower R Negro near Manaus, E to Amapá; also recorded S of Tefé near R Urucu, in W Amazonas).

Descriptive notes. 16·5 cm. Has crown black to dark sooty brownish, large lemon-yellow to canary-yellow coronal patch (mostly concealed); prominent white supercilia meeting on forehead, broader at rear and confluent (or very nearly so) on nape; loral, suborbital, postocular and auricular regions black to dark sooty brownish, fine whitish shaft streaks in suborbital area and on anterior auriculars; upperparts greyish olive-green to dark olive or olive-brown; wings dusky, browner than upperparts, narrow whitish or pale yellowish-white margins on secondaries and tertials, pale greyish-brown or olive edging on wing-coverts, less prominent darker greyish-brown margins on primaries; tail feathers dark greyish-brown with lighter greyish-brown or olive margins; throat and entire underparts, including axillaries and underwing-coverts, plain canary-yellow; iris blackish; bill rather long, black; legs blackish. Differs from very similar *C. albovittatus* in yellow, not white, throat; from *C. trivirgatus* mainly in larger size, blacker crown, yellow coronal patch. Sexes alike. Juvenile undescribed. Voice. Call a distinctive quick, rhythmic, petulant-sounding, and nearly trilled or ringing "quee-le-le", "cue-le-le" or "weedle-de, weedle-de-wee", rather loud and often repeated numerous times.
Habitat. Canopy and borders of wet and humid forest, taller second growth, and occasionally among scattered trees in forest clearings. Mostly below 1000 m, sometimes ranging to 1300 m.
Food and Feeding. Insects; fruits sometimes also taken. Forages mostly in pairs or small groups, occasionally singly; also joins mixed-species flocks but seems not to follow them, and spends equal amount of time in foraging independently. Tends to remain at higher levels in canopy, often perching on top of crown foliage or on exposed twig; frequently changes perches, and bobs head; rarely descends to lower levels, even along forest edge. Actively flits about the vegetation; perch-gleans prey, or makes short sallies to vegetation and branches to hover-glean insects (sometimes fruits); less often, hawks flying insects from the air.
Breeding. Details of nest structure not very well known, but nest reported as being cup-shaped; placed usually rather high up in natural tree hole or cavity, sometimes old woodpecker (Picidae) hole, stuffed with grasses and other fibrous materials; at least one instance of abandoned pendant and bag-shaped nest of a Yellow-rumped Cacique (*Cacicus cela*) being used, the female repeatedly entering with nest material, apparently assembling some structure or modifying bottom of existing nest. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Details unknown; wanders to some degree, but probably resident in most areas.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Possibly more widespread in Colombia; very local in NE Ecuador, only two recent records. Occurs in Jaú National Park, in Brazil. Probably tolerant of some forest degradation, as it occurs also in second growth and in trees in clearings. The only member of genus for which published information on nest and eggs exists, although other details of breeding biology unknown; focused field studies and observations necessary.
Bibliography. Álvarez & Whitney (2003), Anon. (1998a), Birdsley (2002), Clements & Shany (2001), Cory & Hellmayr (1927), Friedmann (1948), Gilliard (1941), Haverschmidt (1968, 1973), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1984), Meyer de Schauensee (1982), Mobley (2002), Naka (2004), Novaes (1978a), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Whittaker & Oren (1999).



344. Three-striped Flycatcher

Conopias trivirgatus

French: Tyran à triple bandeau **German**: Olivbrust-Maskentyrann **Spanish**: Bienteveo Trilistado

Taxonomy. *M[uscicapa] trivirgata* Wied, 1831, Bahia, Brazil.
Has been hypothesized, on basis of hole-nesting behaviour, that genus may be most closely related to *Myiodynastes*, with this clade basal to a "*Tyrannus* group" that also includes *Megarynchus*, *Tyrannopsis*, *Empidonomus* and *Griseotyrannus*; molecular-sequence data, however, do not support an affinity between these two genera, but strongly suggest that present genus is part of that group to the exclusion of *Myiodynastes*. Molecular data strongly indicate that present species and *C. cinchoneti* are sister-species, most closely related to a clade consisting of *C. albovittatus* and *C. parvus*. Races widely separated geographically, possibly represent two separate species. Two subspecies currently recognized.
Subspecies and Distribution.
C. t. berlepschi E. Snethlage, 1914 - Venezuela (S Bolívar), extreme NE Ecuador (E Sucumbíos, E Napo), N Brazil (both banks of lower Amazon, from Manacapurú and Tefé E to Óbidos and Santarém, also Maranhão), E Peru (Loreto, Ucayali, Madre de Dios) and NC Bolivia (Cochabamba).
C. t. trivirgatus (Wied, 1831) - SE Brazil (SE Bahia S to Paraná), E Paraguay (E from Paraguarí) and NE Argentina (Misiones, NE Corrientes).
Descriptive notes. 13·5-14·5 cm. Smallest member of genus. Nominate race has crown and side of head dusky brown, crown completely encircled by long white supercilia from base of bill (not quite connecting across forehead); upperparts mostly rather pale olive, wings and tail dusky, wing-coverts with faint paler tips, tertials with paler margins; bright lemon-yellow below, faint olive tinge on

On following pages: 345. Lemon-browed Flycatcher (*Conopias cinchoneti*); 346. Golden-bellied Flycatcher (*Myiodynastes hemichrysus*); 347. Golden-crowned Flycatcher (*Myiodynastes chrysocephalus*); 348. Baird's Flycatcher (*Myiodynastes bairdii*); 349. Sulphur-bellied Flycatcher (*Myiodynastes luteiventris*); 350. Streaked Flycatcher (*Myiodynastes maculatus*); 351. Boat-billed Flycatcher (*Megarynchus pitangua*); 352. Sulphury Flycatcher (*Tyrannopsis sulphurea*); 353. Variegated Flycatcher (*Empidonomus varius*); 354. Crowned Slaty Flycatcher (*Griseotyrannus aurantioatrocristatus*).

breast; iris dark; bill long, narrow, blackish; legs blackish. Differs from similar *C. parvus* mainly in somewhat smaller size, duller crown without yellow patch, greater contrast between paler upperparts and dark wings; from *Myiozetetes similis* in smaller size, proportionately longer and narrower bill, yellow (not white) throat, no reddish margins on wing feathers. Sexes alike. Juvenile undescribed. Race *berlepschi* is smaller than nominate, has narrower bill, less blackish crown, paler and more yellowish-green upperparts, more prominent greenish tips on tail-coverts, wider and more defined yellowish-grey tips on wing-coverts, no olive tinge on chest and sides. VOICE. Most common call an abrasive and jarring "jew" or "jeeuw", swiftly and frantically repeated; in SE Peru a rather thick-sounding and low-pitched "chu-burr", repeated numerous times and nearly simultaneously by pair-members; call in SE Brazil said to be a muffled "j-j-j".

Habitat. Canopy and borders of humid forest and *várzea*; mostly below 300 m, but observed at 950 m in Venezuela.

Food and Feeding. Insects. Most often seen in pairs or small groups; regularly associates with mixed-species flocks, but appears to spend equal time in foraging alone. Moves through canopy or along forest edge, or perches conspicuously in outer foliage or on top of well-exposed leaves high in crown. Prey caught by aerial hawking, also by short-distance sallies to vegetation.

Breeding. Pair in Argentina in Nov taking leaves to old woodpecker (Picidae) hole 6 m up in broken branch; may compete for suitable cavities with other birds, as said to behave aggressively towards *Myiodynastes maculatus*; said also to establish itself in cacique (*Cacicus*) colonies, perhaps to appropriate hanging nests. No other information.

Movements. Details unknown; wanders to some degree, but probably resident in most areas.

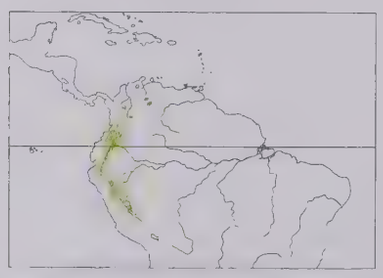
Status and Conservation. Not globally threatened. Rare to locally uncommon. Occurs in Pacaya-Samiria National Reserve, in Peru, Madidi National Park and Pilón Lajas Biosphere Reserve, in Bolivia, Caaguazú, San Rafael and Ybycuí National Parks, in Paraguay, Iguaçu, Jaú and Tapajós National Parks, in Brazil, and Iguazú National Park, in Argentina. Has relatively large range in which much of its habitat is still in good condition. Further study required in order to ascertain more about its ecology and breeding biology.

Bibliography. Begazo & Valqui (1998), Birdsley (2002), Brooks *et al.* (1993), Canevari *et al.* (1991), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Hayes (1995), Hilty (2003), Lanyon (1984a), Lowen *et al.* (1996), Meyer de Schauensee (1982), Mobley (2002), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Oren & Parker (1997), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1958), Whittaker & Oren (1999).

345. **Lemon-browed Flycatcher**

Conopias cinchoneti

French: Tyran à sourcils jaunes **Spanish**: Bienteveo Cejiamarillo
German: Gelbbrauen-Maskentyrann



Taxonomy. *T[yrannus] cinchoneti* Tschudi, 1844, highlands of Junín, Peru.

Has been hypothesized, on basis of hole-nesting behaviour, that genus may be most closely related to *Myiodynastes*, with this clade basal to a "*Tyrannus* group" that also includes *Megarynchus*, *Tyrannopsis*, *Empidonomus* and *Griseotyrannus*; molecular-sequence data, however, do not support an affinity between these two genera, but strongly suggest that present genus is part of that group to the exclusion of *Myiodynastes*. Molecular data strongly indicate that present species and *C. trivirgatus* are sister-species, most closely related to a clade consisting of *C. albovittatus* and *C. parvus*. Geographical limits of races and the differences between them not well defined; may require revision. Two subspecies currently recognized.

Subspecies and Distribution.

C. c. icterophrys (Lafresnaye, 1845) - W Venezuela (Sierra de Perijá, W slope of Andes in W Mérida and W Trujillo, E slope in NW Barinas), Colombia (locally in all three ranges, but doubtfully on E slope of E Andes) and extreme NW Ecuador (Carchi).

C. c. cinchoneti (Tschudi, 1844) - E Ecuador (foothills and subtropical zone on E slope) and N & C Andes of Peru (San Martín, Huánuco, Junín, Cuzco).

Descriptive notes. 16 cm. Has head mostly olive-green, with bright greyish-yellow forehead and broad pale yellow supercilia (nearly confluent on nape); upperparts mostly dark olive; wings and tail dusky brownish, paler edges of tertials; bright yellow below, olive tinge on side of chest; iris dark; bill rather long, black; legs blackish. Differs from *C. parvus* mainly in yellow (not white) supercilium, no yellow coronal patch. Sexes alike. Juvenile undescribed. Race *icterophrys* is very like nominate, perhaps less extensive yellow on forehead, narrower supercilia, paler throat. VOICE. Distinctive call an odd high-pitched nasal, twittering and petulant-sounding "whee-ee-ee-ee, wheedididídí-dí" or "pa'treeer-pa'treeer-pa'treeer", often associated with head-bobbing.

Habitat. Relatively small forest clearings, larger openings with scattered tall trees, and edges of wet and sometimes steep montane cloudforest. Mostly 700-1900 m, occasionally to 2150 m; locally down to 400 m on Pacific slope in Colombia (Anchicayá Valley).

Food and Feeding. Insects and small fruits. Usually in pairs or in small, rather loose groups of 3-5 individuals; occasionally joins mixed-species flocks, but most often forages independently. Perches at higher levels on top of canopy leaves or exposed twigs and branches, well in the open; rather restless, seems not to perch for very long in one place. Makes short sallies to foliage to glean items, sometimes hovering briefly.

Breeding. No information. Group of three individuals observed at an inactive Russet-backed Oropendola (*Psarocolius angustifrons*) colony in E Ecuador, one bird briefly clinging to entrance of a nest, but not known whether they bred there.

Movements. Details unknown; wanders to some degree, and considered to have rather large home range, but probably resident in most areas.

Status and Conservation. Not globally threatened. Rare to locally uncommon. Fairly common in Serranías Cofán (Sucumbíos), in E Ecuador. Occurs in Tambito Nature Reserve, in Colombia, Podocarpus National Park, in Ecuador, and Machu Picchu Historical Sanctuary, in Peru. Tolerant of some forest degradation.

Bibliography. Birdsley (2002), Chapman (1917c, 1921), Clements & Shany (2001), Cory & Hellmayr (1927), Hilty (1997, 2003), Hilty & Brown (1986), Lanyon (1984a), Meyer de Schauensee (1982), Mobley (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001), Zimmer (1937c).

Genus *MYIODYNASTES* Bonaparte, 1857

346. **Golden-bellied Flycatcher**

Myiodynastes hemichrysus

French: Tyran à ventre d'or Spanish: Bienteveo Ventridorado
German: Braunbart-Maskentyrann

Taxonomy. *Hypermitres hemichrysus* Cabanis, 1861, Los Frailes, Costa Rica.

Affinities of genus uncertain; long hypothesized as being closest to *Conopias*, largely on basis of similar hole-nesting tendencies. Genus probably monophyletic, although this only weakly supported by recent analyses of molecular-sequence data (likely due to inappropriate markers for the apparently long branches and deep level of divergence within genus). Results of separate analyses of plumage/syringeal morphology and molecular data were not completely congruent, but do suggest some strong tentative conclusions. Present species and *M. chrysocephalus* originally considered conspecific; recovered as sister-taxa under certain coding schemes of morphological characters, and as a clade with very strong bootstrap support in all analyses of molecular data. Monotypic.

Distribution. Costa Rica (S from Volcán Miravalles, in Cordillera de Guanacaste) and W Panama (E to Veraguas).

Descriptive notes. 18-20 cm; 41 g. Has crown and nape dusky greyish-olive or dark sooty grey, finely streaked with black, paler and greyer towards forehead (sometimes mixed with dull whitish), large yellow coronal patch (semi-concealed); broad white supercilium, broad blackish stripe through lores and auriculars, whitish cheekstripe, dark greyish-olive or dusky malar streak; upperparts plain olive-green, rump and uppertail-coverts greenish-olive, tail-coverts with indistinct buffish-olive or cinnamon terminal margins; wings dusky greyish-brown, inner primaries and outer secondaries with narrow cinnamon edging, inner secondaries with broader whitish-yellow edging, greater wing-coverts with narrow cinnamon or cinnamon-buff margins, sometimes just terminal margins on middle coverts; tail deep greyish-brown, rather broad pale cinnamon or cinnamon-buff edges on inner webs of rectrices, sometimes also less distinct edging on outer webs; chin whitish, mostly deep lemon-yellow below, more canary-yellow on throat, some broad but faint olive lateral streaking on chest, less distinctive olive streaking on side of breast; axillaries and underwing-coverts bright yellow; iris brown; bill black or brownish-black, basal part of lower mandible more brownish, prominent rictal bristles; legs dusky. Differs from *M. chrysocephalus* mainly in greener upperparts, yellower underparts, and supercilium broader behind eye. Sexes alike. Juvenile is similar to adult, but lacks yellow coronal patch, is more brownish olive-green above, paler and slightly buffy below, also with cinnamon-rufous edging on both webs of remiges and broader margins on greater wing-coverts. VOICE. Most common call a harsh and wheezy, yet excited and high-pitched "syup", "seeeik", "skeé-eey" or skweey", and more complex "seek-a-skeeeir", "skeé-kit skeé-lit skeé-kit" or "chwit-chwit-ti-ti-tit-twit"; also melancholy "pee-ah" or "peeeir", similar to voice of *Myiozetetes similis*; repeated heavy chipping call when agitated. Dawn song said to be a clear and musical "tree-le-loo", repeated numerous times.

Habitat. Canopy and edges of wet montane cloudforest; especially common along watercourses and edges of forest clearings or treefall gaps. Mostly 700-1850 m on Caribbean slope, and to 2300 m on Pacific slope.

Food and Feeding. Fruits and insects. Usually seen in pairs throughout year; also in small family groups, especially during period of several months after breeding season. Sits on exposed perch, usually at middle to higher levels; makes short upward sallies to glean items from vegetation, hawks flying insects in air.

Breeding. Mar-May in Costa Rica. Nest a shallow and rather untidy but solid cup of fine rootlets and moss, often well camouflaged, placed 6-30 m above ground within nook or pocket of moss or in crevice formed by roots and clumping of epiphytes on high branch; also in old woodpecker (Picidae) hole, or in niche among ferns and other vegetation on vertical surface of bank or cliff. Clutch 3 eggs; no information on incubation and fledging periods.

Movements. Probably resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Uncommon to locally fairly common. In Panama, uncommon in valley of R Chiriquí Viejo around Nueva Suiza and Bambito, in W Chiriquí; more common farther E, in Fortuna region. Occurs in Rancho Naturalista and Tapantí National Park, in Costa Rica. Highland forests in its range have been extensively destroyed by burning, logging and agricultural conversion; 50% of Costa Rica's forests lost since 1940, and current deforestation rate of c. 3% makes it likely that in near future forests will remain only in protected areas. In Panama E of Chiriquí only fragments are left, and local extinction of forest-dependent species is considered likely.

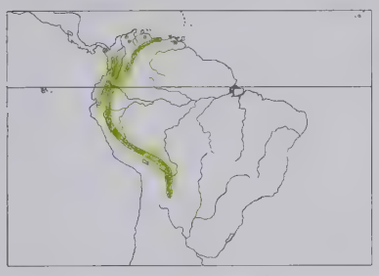
Bibliography. Anon. (1998a), Birdsley (2002), Blake (1958), Cabanis (1861), Cory & Hellmayr (1927), Eisenmann (1955), Fogden (1993), Lanyon (1984a), McLellan (1938), Mobley (2002), Ridgely & Gwynne (1989), Ridgway (1907), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

347. **Golden-crowned Flycatcher**

Myiodynastes chrysocephalus

French: Tyran à casque d'or **German**: Andenmaskentyrann **Spanish**: Bienteveo Coronidorado

Taxonomy. *Sc[aphorhynchus] chrysocephalus* Tschudi, 1844, Chanchamayo, Junín, Peru.



Affinities of genus uncertain; for long hypothesized as being closest to *Conopias*, largely on basis of similar hole-nesting tendencies. Genus probably monophyletic, although this only weakly supported by recent analyses of molecular-sequence data (likely due to inappropriate markers for the apparently long branches and deep level of divergence within genus). Results of separate analyses of plumage/syringeal morphology and molecular data were not completely congruent, but do suggest some strong tentative conclusions. Present species and *M. hemichrysus* originally considered conspecific; recovered as sister-taxa under certain coding schemes of morphological characters, and as a clade with very strong bootstrap support in all analyses of molecular data. Three subspecies currently recognized.

Subspecies and Distribution.

M. c. minor Taczanowski & Berlepsch, 1885 - E Panama (Cerro Tacarcuna and Cerro Pirre, in Darién), W & E Colombia (throughout Andes, also La Macarena Mts in S Meta) and Ecuador (S on W slope to Alamor area of W Loja).

M. c. cinerascens Todd, 1912 - N Colombia (Sierra Nevada de Santa Marta) through Sierra de Perijá to mountains of W & N Venezuela (Andes, and in C Falcón coastal mountains E to Sucre and N Monagas).

M. c. chrysocephalus (Tschudi, 1844) - Peru (C & E Andes from San Martín S to N Puno, also recorded in W cordillera in Bosque de Cuyas), W Bolivia (La Paz S to Chuquisaca and Tarija) and extreme NW Argentina (N Salta).

Descriptive notes. 19-22 cm; 37 g. Nominate race has brownish-grey or dusky crown, golden-yellow crown patch (semi-concealed), long and broad white supercilium; side of head greyish dusky, buffy white on lower cheek and into throat area, broad and somewhat blurred dusky malar streak; upperparts mostly dull olive; rump and uppertail-coverts greenish-olive, tail-coverts with buffy or cinnamon terminal margins; wings dusky, some rufous or tawny-buff edging on remiges and wing-coverts; tail dusky, some rufous edging on rectrices; chin white, becoming dull pale buffy on throat; mostly pale yellow below, especially lower underparts, chest more buffy yellow and clouded or flammulated with pale greyish-olive or olive, more prominent olive streaking on breast side; iris blackish; bill rather large and heavy, black, prominent rictal bristles; legs blackish. Distinguished from *M. hemichrysus* mainly by somewhat paler coloration, less contrasting head pattern. Sexes alike. Juvenile lacks coronal patch, has buffier supercilium, greyer upperparts, less streaked below. Race *cinerascens* is slightly smaller than nominate, has wider and more prominent cinnamon-rufous margins on wing and tail feathers, more buff on throat; *minor* is like previous, perhaps darker and more brownish-olive above. Voice. Typical song is short "tuiewee", "tuieweet" or "pieuee" repeated every 1-3 seconds. Common calls, usually from open or partially protected perch in canopy, often somewhat lower, are very loud, quite raucous and angry-sounding, persistently "squeeé-yu", "kiss-you", "skéézz-u", or squealing "skweé-ah"; voice has been likened to sound made by squeezing a rubber bath toy. Alarm call is sharp "kvuie" or "kvuie-kvuie". Dawn song a repeated "squeeé-yu-d'r'r'r".

Habitat. Humid or wet foothill and montane woodland or forest borders, moderately sized openings created by landslides or fallen trees within forest, larger clearings or higher-elevation pasture with scattered tall trees near forest; occasionally along roads, often along swift mountain streams. Mostly 900-2500 m, but up to 2800 m in Santa Marta and Perijá Mts, Andes and coastal ranges of N Venezuela; drops lower, down to 600 m in Venezuela, and to 400 m on Pacific slope in Colombia (Valle) and Ecuador.

Food and Feeding. Insects and fruits. Analysis of 25 prey items (mean length 10 mm) taken from stomachs in SE Peru gave: Coleoptera (68%); Homoptera (Pentatomidae 16%); and Hymenoptera (wasps 12%, ants 4%). Most often observed singly or in pairs; occasionally joins mixed-species flocks, usually for brief periods, but more often forages independently. Perches at various levels, usually lower to middle ones, on conspicuous and fully exposed limb; perches erect, but with slightly hunched posture, often nodding head. Hawks flying insects; hover-gleans or upward strikes for insects and fruits in canopy.

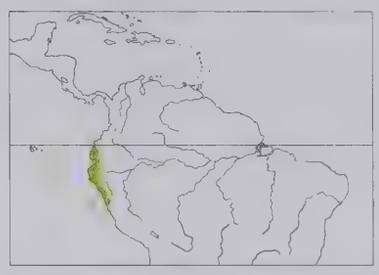
Breeding. Birds in breeding condition in May-Jul and eggs and fledglings in Aug in Colombia; eggs in Jan and Jun in Venezuela; fledglings in Jan, Jun, Jul and Sept in Ecuador; May in Peru. Nest not very well known, described as cup-shaped and usually composed primarily of moss; placed in variety of situations, most often in tree cavity or hole on vertical surface, sometimes on cliff ledge or in natural crevice or niche among rocky walls adjacent to roadcut. Clutch 2 eggs; no information on incubation and fledging periods.

Movements. Not well known, but some seasonal movement likely; in Venezuelan Andes said to be erratic and scarce in Jan-Mar, but especially vocal and conspicuous in Jun and Jul.

Status and Conservation. Not globally threatened. Uncommon to common. Range apparently expanding, and abundance probably increasing, as a consequence of road construction. Occurs in several protected areas, e.g. Henri Pittier National Park, in Venezuela, Tinigua National Park and Tambito Nature Reserve, in Colombia, Machu Picchu Historical Sanctuary, in Peru, and Madidi National Park and Pilón Lajas Biosphere Reserve, in Bolivia. Given the species' level of abundance and its tolerance of some forest degradation, it is considered unlikely to become threatened in near future.

Bibliography. Anon. (1998a), Begazo (1995), Birdsley (2002), Blake (1962), Chapman (1917c, 1921), Chebez (1994), Clements & Shany (2001), Cory & Hellmayr (1927), Delgado (1985), Ewert (1975), Fjeldså & Krabbe (1990), Flanagan & Vellinga (2000), Hilty (1997, 2003), Hilty & Brown (1986), Lanyon (1984a), Meyer de Schauensee (1982), Mobley (2002), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Stotz *et al.* (1996), Walker (2001), Wetmore (1939, 1972), Williams & Tobias (1994), Zimmer (1930).

348. Baird's Flycatcher



Myiodynastes bairdii

French: Tyran de Baird **German**: Pazifischer Maskentyrann **Spanish**: Bienteveo de Baird

Taxonomy. *S[aurophagus] bairdii* Gambel, 1847, California; error = Guayaquil, Ecuador.

Affinities of genus uncertain; for long hypothesized as being closest to *Conopias*, largely on basis of similar hole-nesting tendencies. Genus probably monophyletic, although this only weakly supported by recent analyses of molecular-sequence data (likely due to inappropriate markers for the apparently long branches and deep level of divergence within genus). Findings from separate analyses of plumage/syringeal morphology and molecular data were not completely congruent, but evidence indicates that present species is basal to two main clades, one containing *M. hemichrysus* and *M. chrysocephalus* and the other *M. luteiventris* and *M. maculatus*. Monotypic.

Distribution. SW Ecuador (C Manabí, from N side of Bahía de Caráquez, S to El Oro and W Loja) and NW Peru (S on Pacific slope to Ancash and to N Lima).

Descriptive notes. 23 cm. Has crown and nape sandy brown, crown lightly streaked grey, yellow coronal patch (semi-concealed); conspicuous broad black mask from forehead and through eye to ear-coverts, bordered above by sharply contrasting pale sandy-brown area; upperparts mostly olive-brown, becoming more rufous on rump; wings dusky, broad cinnamon-rufous margins on remiges and wing-coverts; tail mostly rufous, outermost rectrices with some dusky edging; throat whitish, rather obscurely streaked greyish; underparts largely pale creamy yellow, chest and breast area more pale ochraceous with somewhat indistinct greyish streaking; iris dark; bill rather heavy, mostly blackish, base of lower mandible pinkish; legs grey to blackish. Sexes alike. Juvenile undescribed. Voice. Not particularly vocal. Usual call, primarily at dawn (less often at dusk) from partially concealed perch, a hoarse-sounding "worr-sheéit worr-sheéit" or "wrrr-yeeít wrrr-yeeít", steadfastly repeated at intervals of 2-4 seconds and sometimes followed by ascending and more jumbled phrase.

Habitat. Arid lowlands, foothills and littoral areas with deciduous woodland or more arid scrub with some scattered tall trees, most common at borders; occasionally found in settled areas, especially in gardens. Mostly below 1000 m.

Food and Feeding. Larger insects; considerable quantities of fruit also consumed. Most often observed in pairs, perched conspicuously in the open at various heights, usually at higher levels; sometimes perches on telephone and other wires or on fences in human settlements. Insects taken by sally-gleaning to foliage, sometimes dropping to the ground in pursuit of prey.

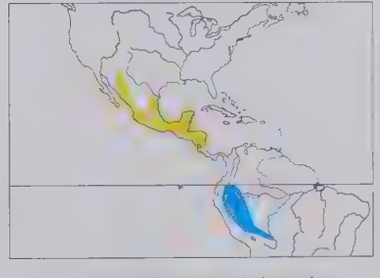
Breeding. Eggs in Feb. Nest is a large, well-built cup of twigs with a neat lining of fine plant stems and roots, placed 10 m above ground in natural or man-made crevice or hole (e.g. under roof thatching or in electric light standards). Clutch 3-5 eggs; both sexes attend the young; no information on incubation or nestling periods.

Movements. Not well known, but likely resident throughout range.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Uncommon to fairly common. Especially numerous around Zapotillo (Loja), in Ecuador. Occurs in Cerro Blanco Forest Reserve, Machalilla National Park and Loma Alta Ecological Reserve, in Ecuador, and Northwest Peru Biosphere Reserve, in Peru. Forests within Tumbesian region are being rapidly destroyed, degraded and fragmented by deforestation and by understorey disturbance resulting from timber extraction and livestock grazing. In W Ecuador, forest below 900 m has disappeared at rate of 57% per decade from 1958 to 1988, and virtually all lowland forest outside protected areas likely soon to have been lost; at higher elevations deforestation has been slower, but overall still less than 5% of original forest cover remains, mostly on inaccessible slopes. Even protected areas suffer from logging, livestock grazing, illegal settling and habitat clearance by people with land rights.

Bibliography. Best & Clarke (1991), Birdsley (2002), Butler (1979), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Ewert (1975), Koepcke (1970), Lanyon (1984a), Marchant (1960), Meyer de Schauensee (1982), Mobley (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Stotz *et al.* (1996).

349. Sulphur-bellied Flycatcher



Myiodynastes luteiventris

French: Tyran tigré **Spanish**: Bienteveo Ventriazufrado
German: Nördlicher Fleckenmaskentyrann

Taxonomy. *Myiodynastes luteiventris* P. L. Sclater, 1859, Orizaba, Veracruz, Mexico.

Affinities of genus uncertain; for long hypothesized as being closest to *Conopias*, largely on basis of similar hole-nesting tendencies. Genus probably monophyletic, although this only weakly supported by recent analyses of molecular-sequence data (likely due to inappropriate markers for the apparently long branches and deep level of divergence within genus). Results of separate analyses of plumage/syringeal morphology and molecular data were not completely congruent, but evidence strongly suggests that present species is sister to *M. maculatus*, and that the two are sister-group to a clade consisting of *M. hemichrysus* and *M. chrysocephalus*. Specimens S from Guatemala evidently have heavier streaking on chest and throat and smaller bill than birds from Mexico, but differences deemed too inconstant to warrant subspecific separation. Monotypic.

Distribution. Breeds SW USA (mountains in S Arizona), Mexico (S on both slopes from Sonora, E Nuevo León and Tamaulipas), Guatemala and Belize S to Costa Rica. Winters E Ecuador, E Peru, extreme W Brazil (along R Juruá, in Acre) and Bolivia (S to Cochabamba and W Santa Cruz).

Descriptive notes. 19-22 cm; 45 g. Has greyish-olive crown, becoming more hoary grey or greyish-white on forehead, golden-yellow coronal patch (semi-concealed); whitish supercilium and cheekstripe contrasting sharply with thick black eyestripe, and with broad, dusky and heavily streaked to nearly solid malar stripe that continues across chin; upperparts largely light olive to brownish-grey, usually tinged buffy, and with broad but fairly indistinct dusky streaking; lower rump and uppertail-coverts cinnamon-rufous, streaked dusky; wings dark brown to blackish, yellowish-white or pale buff to primrose-yellow edging on, especially, inner secondaries and outer webs of median and greater wing-coverts, fairly broad pale greyish-olive or buffy-greyish edges on inner webs of medians, primary coverts and primaries, sometimes paler cinnamon margins on outer coverts; tail bright cinnamon-rufous with dusky shaft stripes, broadest on middle rectrices; chin and side of throat greyish or greyish-olive with broad dusky streaks, rest of throat whiter and with lighter streaking; underparts pale lemon-yellowish, broad dusky streaking on chest, narrower dusky streaking on flanks; axillaries and underwing-coverts lemon-yellow, axillaries with narrow dusky shaft streaks; iris brown; bill fairly stout, broad, dusky blackish, base of lower mandible pinkish or horn-coloured; legs blackish. Differs from *M. maculatus* in smaller bill with less pink at base, longer and broader dusky malar streak, less prominent and more whitish margins on wings, yellow lower underparts with no streaking on crissum. Sexes similar, possibly some minor differences (details unknown). Juvenile lacks

yellow coronal patch (but crown feathers said to have cinnamon-orange bases), has more extensive cinnamon-buff edgings on distal secondaries and wing-coverts, somewhat brighter upperparts with cinnamon-buff feather bases and margins, sometimes duller yellow underparts. Voice. Variety of high-pitched, forceful, quarrelsome-sounding and squeaky whistled phrases, including penetrating "toowí drrip", "wee-dee-yoo", "wee'iz-uh" or "weez-ih" (reminiscent of sound of child's plastic squeaky toy); also loud sharp call preceded by series of staccato notes, "p'p'p'peeee-ya", "kip-kip-kip squellya-squellya" or "pek, pek, pek kweez-i-zik kweez-i-zik", may be extended in longer series or shortened to high, penetrating "kee-zee'ick! kee-zee'ick!", even shorter but equally emphatic and squeaky "squeez-ya", "weel-yum", "pyeeeeuh", or forceful "seedeeyee"; softer and more melodious "tre-le-re-re", low nasal "kweeda kweeda" and hollow series of nasal "ket" notes rapidly climaxing in high-pitched loud squealing also given. Dawn song a bright, slightly slurred phrase followed by clipped, slightly liquid phrase, "chee-a-leet s-lik" or or "doo-ee ti-chu" or similar, continuously repeated, often for several minutes at a time. Migrants in South America usually rather quiet, but sometimes begin to give "squeez-ya" call in period prior to returning N.

Habitat. Canopy and edges of humid forest (both *terra firme* and *várzea* on wintering grounds) to semi-arid mixed or deciduous woodland in montane canyons with many sycamore (*Platanus*) and walnut (*Juglans*) trees; also along mountain streams, and in secondary and gallery woodland, plantations, and shrubby clearings with scattered tall trees. Generally between 1500 m and 1800 m in mountainous areas in N parts of breeding range, and from lowlands to 2000 m on Pacific slope but not below 600 m on Caribbean slope in Costa Rica; mostly below 1000 m in South American non-breeding range, but recorded to 2600 m on passage in Colombia.

Food and Feeding. Insects; also eats considerable quantities of berries and arillate seeds (e.g. of *Bursera* and *Trichilia*), especially on wintering grounds. Seen mostly singly or in pairs; usually in family groups after breeding season in Costa Rica. Usually perches high in canopy; generally inconspicuous unless vocalizing. Insects taken by aerial hawking from a high open perch, or by sally-gleaning among canopy foliage; berries and fruits often plucked in flight.

Breeding. Nests with eggs in Apr-Jun. Nest cup-shaped, composed primarily of small twigs, dry inflorescences and leaf petioles and rachises, often from walnut trees, lacks any significant lining; usually at middle to upper levels (3-27 m) inside natural tree cavity (hole created by branch rotting and falling close to bole) or in old hole of woodpecker (Picidae) or Resplendent Quetzal (*Pharomachrus mocinno*), often in tree within or at edge of clearing; female fills cavity with coarse twigs and leaves to near level of opening before constructing cup. Clutch 2-4 eggs; incubation by female, period c. 16 days; chicks fed by both parents, fledging period 16-18 days.

Movements. Migratory; winters in South America in W & SW Amazonia, from Ecuador S to Bolivia. Leaves breeding grounds mainly in Sept; present on wintering grounds mostly Oct-Apr, but some seem to remain until May and even into Jun; transient in Panama (primarily Sept-Oct and Mar-Apr) and Colombia (most records Oct, also Mar-Apr), with no evidence of overwintering. Present Mar-Sept in Mexico; in Costa Rica, breeding birds arrive Mar to early Apr, and migrants from N appear by early Aug and depart by mid-Oct. Casual in USA in S California, SW New Mexico and coast of W Texas.

Status and Conservation. Not globally threatened. Fairly common in most of breeding range. Fairly common in non-breeding range (e.g. in Peru). Occurs in several protected areas in both parts of range. Not dependent on intact forest, and able to survive in second growth, plantations and clearings; considered unlikely to be at any risk.

Bibliography. Baicich & Harrison (1997), Bendire (1895), Bent (1942), Binford (1989), Birdsley (2002), Brandt (1951), Contreras (1997), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), Fjeldså & Krabbe (1990), Fitzpatrick (1980a), Brodkorb (1943), Gómez & Aguilar (1998), Henshaw (1875), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Kaufman (1996), Land (1970), Lanyon (1984a), Lee Jones (2004), Ligon (1971), Lowther & Stotz (1999), Meyer de Schauensee (1982), Mobley (2002), Monroe (1968), Paynter (1995), Pearson (1980), Price *et al.* (1995), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson (1997), Rowley (1966, 1984), Schaldach (1963), Sibley (2000), Skutch (1960), Slud (1964, 1980), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Udvardy (1963), Wetmore (1972), Willis (1980), Zimmer (1930).

350. Streaked Flycatcher

Myiodynastes maculatus

French: Tyran audacieux **German**: Südlicher Fleckenmaskentyrann **Spanish**: Bienteveo Rayado

Taxonomy. *Muscicapa maculata* Statius Muller, 1776, French Guiana.

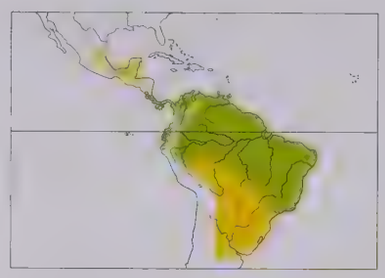
Affinities of genus uncertain; for long hypothesized as being closest to *Conopias*, largely on basis of similar hole-nesting tendencies. Genus probably monophyletic, although this only weakly supported by recent analyses of molecular-sequence data (likely due to inappropriate markers for the apparently long branches and deep level of divergence within genus). Results of separate analyses of plumage/syringeal morphology and molecular data were not completely congruent, but evidence strongly suggests that present species is sister to *M. luteiventris*, and that the two are sister-group to a clade consisting of *M. hemichrysus* and *M. chrysocephalus*. Has been suggested that race *solitarius* may represent a separate species, on basis largely of differences in plumage, but apparent intermediate forms from N Brazil (S Amazonas) and general similarity in voice to other races argue against this. Otherwise, clearly observable differences between supposed races from localities as widely separated as N Venezuela, the Guianas and NE & S Brazil are lacking; close re-evaluation and probably revision required. Seven subspecies currently recognized.

Subspecies and Distribution.

M. m. insolens Ridgway, 1887 - breeds E & SE Mexico (SW Tamaulipas S to Puebla, N Oaxaca and N Chiapas, E to S Yucatán and Quintana Roo), N Guatemala, Belize and NW Honduras; migrates S to N South America.

M. m. difficilis J. T. Zimmer, 1937 - W Costa Rica S to Panama (including Coiba I and Cébaco), Colombia (except N & W) and W Venezuela (W of Andes in Zulia and Táchira, W Falcón E to Curimagua, and E base of Andes S from Portuguesa).

M. m. nobilis P. L. Sclater, 1859 - N Colombia (Córdoba E in coast region to Sierra Nevada de Santa Marta and W side of Sierra de Perijá).



M. m. tobagensis J. T. Zimmer, 1937 - Venezuela (except W, but including Margarita I), Trinidad and Tobago, and Guyana.

M. m. chapmani J. T. Zimmer, 1937 W Colombia (S from Serranía de Baudó in Chocó, absent or local in SW lowlands), W Ecuador and extreme NW Peru (S to Piura, also recorded Arequipa).

M. m. maculatus (Statius Muller, 1776) - Surinam, French Guiana, N Brazil (upper R Negro S to S bank of R Amazon, E to NW Maranhão) and E Peru (R Napo and R Ucayali area).

M. m. solitarius (Vieillot, 1819) - breeds C & S Peru and C & E Brazil S to E Bolivia, Paraguay, Argentina (S to San Luis, La Rioja, Córdoba, La Pampa and N Buenos Aires) and Uruguay; S populations migrate N.

Descriptive notes. 19·5-23 cm; 43-45 g. Nominate race has buffy to cinnamon crown heavily but indistinctly streaked dusky, semi-concealed bright yellow (sometimes tinged orange-rufous) coronal

patch; pale buff- yellowish to dull yellowish-white forehead and supercilium (with narrow dusky streaking) and pale yellowish to dull buff-whitish lower cheek contrasting with broad blackish or dusky (sometimes tinged browner) eyestripe through lores and auriculars; malar region whitish, more pale buffy anteriorly and brown posteriorly, prominently streaked dusky; upperparts more or less light brown, usually prominently suffused with cinnamon-brown or buffy brown, with bold black or dusky streaks, back, scapulars and upper rump more light greyish-brown or olive and conspicuously streaked dusky, lower rump and uppertail-coverts mostly cinnamon-rufous with narrow dusky shaft streaks; wings dusky, primaries and secondaries with cinnamon-rufous margins, tertials with broad pale yellowish-buff or buff-white edges, lesser and median wing-coverts with broad light cinnamon-rufous margins, greater coverts broadly edged more cinnamon-buff; tail cinnamon-rufous with dusky stripe along rachis, broadest on innermost feather pair and gradually expanding terminally; more or less dull whitish below, well suffused with pale sulphur-yellow (especially on breast, side and undertail-coverts), chin and throat side narrowly streaked dusky, prominent dusky streaks on breast, sides, flanks and crissum, streaks broadest on chest and anterior part of side; iris brown; upper mandible deep brownish (darkest terminally), lower mandible slightly duller brownish (more dusky terminally and along tomium) and with extensive pinkish towards base; legs dark greyish. Differs from similar *M. luteiventris* mainly in larger and heavier bill with more extensive pinkish at base, yellower supercilium, less obvious malar streak, rufous (not whitish) wing edgings, paler yellow on underparts. Sexes alike. Juvenile is similar to adult, but crown more rufous and lacking yellow coronal patch, has more extensive rufous edging on wings, less yellow suffusion on underparts. Races somewhat variable, and some apparently inseparable from others: *insolens* is paler and more olivaceous above than nominate, with narrower streaking above, more yellowish supercilium, narrower and paler margins on remiges, much narrower and less extensive streaking below (crissum almost unstreaked), perhaps longer wings and shorter tail and bill; *nobilis* is generally paler and more buffy above than nominate, with greater yellowish suffusion and less heavy streaking below; *solitarius* is most distinctive, with blacker and more prominent streaking overall, mostly whitish wing margins, predominantly blackish tail with very narrow rufous edgings on rectrices; other races are variable. Voice. Variety of rather loud and raucous calls, most commonly a harsh and sharp nasal "chup", "eéchup", "behk", "kik", "chek" or "pehk" that is sometimes steadily repeated; also slightly liquid and sometimes excitedly repeated "w-see'u", "chuk-yi", "tsu ka" or "t-cheu", and harsh chattering "chi w-chi ki-chi w-chi ki-chi". Dawn song (also given at dusk in many regions) quite melodious, a loud and quickly repeated "wheeé-cheederee-wheeé", sometimes lacking last note; in Costa Rica and Panama described as persistently repeated, soft, clear, liquid and unexpectedly melodious "kawee-teedly-wink", "whee-cheerily-chee" or "whee´-cheederee-che´", in Colombia as squeaky and slightly musical "wheet-siddle-whít", and in Venezuela as quick, rhythmic "wéét, wiggle-your-feet!" given repeatedly without pausing; in Brazil, a song given at dusk described as resonant and descending "dlui-dluee-gwik", repeated.

Habitat. Evergreen to semi-deciduous forest, open second-growth woodland and gallery forest, edges and moderate clearings with sufficient scattered tall trees, sometimes in trees around houses and agricultural areas, mangroves, and *caatinga*; also in younger and more open *várzea* and river islands in Amazonia, seeming to eschew more humid or well-forested areas. Mostly below 1500 m, but to 1650 m in Panama (W Chiriquí), 2000 m in Venezuela, and 3000 m in C Colombian Andes (Puracé).

Food and Feeding. Insects, including especially cicadas (Cicadidae), wasps and flying ants (Hymenoptera); small lizards and considerable quantities of small berries and arillate fruits also consumed, especially by austral migrants. Usually solitary or in pairs, but sometimes in loose flocks during migration; occasionally joins mixed-species foraging flocks. Often rather noisy and thus quite conspicuous, but sometimes perches silently for prolonged periods. Perches at all heights, but usually at middle levels or higher. Most often makes short sallies and hover-gleans among thick canopy foliage and from branches; also aerial hawks flying insects from high exposed perch.

Breeding. March-May in Costa Rica; in Colombia, birds in breeding condition Mar-Jun and juveniles by Jul in N, and in breeding condition Jan in SW (Huila); breeding Mar-Apr in N Venezuela and Mar-Jul in Trinidad and Tobago; Nov-Jan in Argentina. Nest, built by female, a shallow cup (two in Argentina 8-9 cm in diameter, 8 cm tall, 3-5 cm deep) composed of dry compound leaf petioles and rachises and flower stalks, lined with finer leaf rachises, usually placed at middle to upper levels (5·5-23 m) in natural cavity or large woodpecker (Picidae) or quetzal (*Pharomachrus*) hole (entrance of one in Argentina 13 × 11 cm) in dead or decaying tree at forest edge or within clearing, sometimes on ledge under eaves of house, in nestbox, or in crevice among bases of palm fronds or niche among vine tangles; old nest of Rufous Hornero (*Furnarius rufus*) sometimes used in Argentina; when cavity or crevice is deep, female often raises level of nest foundation by filling recess with coarse materials; often perches conspicuously near nest, as if on guard. Clutch 2-3 eggs, sometimes 4; incubation by female, period 16-17 days; nestlings fed by both parents, fledging period 17-21 days. Nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. Migratory in N & S of range. N breeders present late Mar to Sept on Atlantic slope from Mexico S to W Honduras, winter S to Panama and N South America; in Costa Rica, S migration occurs late Jul to early Sept and N passage Feb-Mar; migrants recorded in Panama Feb-Apr, but presumably also present in autumn (probably Sept-Oct). Those breeding from S Peru and C & SE Brazil S to Boliva and C Argentina (race *solitarius*) migrate N, spending non-breeding period (mostly Apr-Sept) E of Andes N to E Colombia and N South America, with single records from N Chile (Atacama) and SW Peru (Arequipa); migrants occur primarily May-Jul and Dec in Colombia, recorded Mar-Sept in Venezuela (mainly S of R Orinoco), and present Apr-Aug in Ecuador. In addition, some local elevational movement by resident races apparent in Venezuela.

Status and Conservation. Not globally threatened. Uncommon to locally common. Has very large range, within which it occurs in numerous national parks and other protected areas. Adaptable; found in many types of wooded habitat, and not dependent on intact forest; survives well in degraded habitats and tolerant of human presence.

Bibliography. Anon. (1998a), Babarskas *et al.* (2003), Barrows (1883), Binford (1989), Birdsley (2002), Bond *et al.* (1989), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Clements & Shany (2001), Contreras (1988), Cory & Hellmayr (1927), Di Giacomo (2004), ffrench (1991), Fitzpatrick (1980a, 1985a), Fjeldså & Maijer (1996), Friedmann (1927), Friedmann & Smith (1950), Guix (1995), Haffer (1975), Hartert & Venturi (1909), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hayes & Samad (2002), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Johnson (1967), Joseph (1996), Klimaitis & Moschione (1987), Lanyon (1984a), Lee Jones (2004), Lowen *et al.* (1996), Machado & Rodrigues (2000), Miller (1947), Miserendino (1998), Mobley (2002), Moermond & Denslow (1985), Monroe (1968), Narosky & Salvador (1998), Olson (1997), Oren & Parker (1997), de la Peña (1988, 1999), Pereyra (1937), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson (1997), Robinson & Terborgh (1997), do Rosário (1996), Schönwetter & Meise (1968), Short (1975), Sibley & Ahlquist (1985c), Sick (1993, 1997), Skutch (1960, 1985),

Genus *MEGARYNCHUS* Thunberg, 1824

351. **Boat-billed Flycatcher**

Megarynchus pitangua

French: Tyran pitangua **German**: Starkschnabel-Maskentyrann **Spanish**: Bienteveo Pitanguá

Taxonomy. [*Lanius*] *Pitangva* [*sic*] Linnaeus, 1766, Rio de Janeiro, Brazil.
Affinities of genus uncertain. Syringeal morphology, nest architecture and molecular-sequence data indicate a sister relationship with *Tyrannopsis*; molecular data provide conflicting but fairly weak evidence for the two being either the sister-group to *Conopias*, or basal to a group including *Conopias* as sister to a well-supported clade containing *Empidonomus*, *Griseotyrannus* and *Tyrannus*, but additional sequence data necessary in order to resolve true affinities among these taxa. Trinidad birds described as race *parvirostris* on grounds of supposedly smaller bill, but considered otherwise indistinguishable from South American birds. Some races seem readily distinguishable, others less so; populations of nominate from S Brazil and Paraguay appear somewhat larger and darker on average than those in N, but much individual variation; critical re-evaluation of races is needed. Six subspecies currently recognized.
Subspecies and Distribution.
M. p. tardiusculus R. T. Moore, 1941 - W Mexico (SW Sinaloa, W of main Sierra Madre, S to W Nayarit).
M. p. caniceps Ridgway, 1906 - W Mexico (SW Jalisco).
M. p. mexicanus (Lafresnaye, 1851) - E & S Mexico (from S Tamaulipas in E, from Guerrero in W) S to Panama and NW Colombia (NW Chocó S to R Juradó).
M. p. deserticola Griscom, 1930 - arid valley of R Negro, in C Guatemala.
M. p. pitangua (Linnaeus, 1766) - N, C & E Colombia (Caribbean lowlands, Magdalena Valley S to Huila, and throughout E of Andes), Venezuela, Trinidad, the Guianas, E Ecuador (except Zamora area), E Peru, Brazil (S to Rio Grande do Sul), N & E Bolivia, Paraguay and NE Argentina (S to E Formosa and Corrientes).
M. p. chrysogaster P. L. Sclater, 1860 - W Ecuador (S from W Esmeraldas) and extreme NW Peru (Tumbes, N Piura), possibly crossing Andes into S Ecuador.

Descriptive notes. 21-5-24 cm; 62-70 g. Nominate race has blackish-brown or dull sooty-black crown, yellow to orange-rufous coronal patch (semi-concealed); long, broad and conpicuously contrasting white supercilia extending to side of forehead meeting (or nearly so) on nape; broad black band from lores to auriculars dull slate-black, white malar region; upperparts mostly olive to dull brownish-olive; wings dusky brownish, rather inconspicuous narrow pale cinnamon or rufous edgings (sometimes lacking); tail rather short, dusky brownish with narrow pale cinnamon or rufous edgings; throat white; underparts, including axillaries and underwing-coverts, bright yellow; iris brown; bill exceptionally broad and heavy, rather long with a strongly arched culmen, blackish, base of lower mandible sometimes more brownish; legs blackish. Distinguished from superficially similar *Pitangus sulphuratus* and *Myiozetetes similis* by large size, brownish wings and tail, more olivaceous upperparts, unusually stout and exceptionally broad bill. Sexes alike. Juvenile is similar to adult, but lacks coronal patch, has broader cinnamon or rufous edgings on wing (more whitish on inner secondaries) and tail, supercilium tinged yellow, also generally darker and more brownish above with cinnamon to dull rufous feather edges. Races vary mainly in plumage tones and prominence of edgings: *mexicanus* has brighter or more greenish-olive upperparts than nominate, no rufous margins on rectrices, and in NW Colombia said to have coronal patch tawny-orange; *caniceps* differs from previous in more greyish crown, more greyish-olive upperparts; *tardiusculus* and *deserticola* are similar to previous two; *chrysogaster* is similar to nominate, but has more prominent rufous margins on remiges and upperwing-coverts, slightly richer yellow underparts, and coronal patch supposedly always tawny-orange (not yellow or orange-yellow). Voice. Common calls, sometimes accompanied by head-bobbing, varied, loud, rather harsh and slightly squealing, readily noticeable, include gruff and often rattling, stuttering or quavering "kwée'le", "eeihrrr", "krrrah", "neeeeeah" or "keerrrrr-eék", gruff and quarrelsome "quee-zika quee-zika" or "eehr, eehr ki-di-rrik" and similar, nasal whiny "er-er-er-erk", nasal and mocking "nya-nya-nya-nya", and rapidly repeated loud "choip choip"; race *chrysogaster* (W of Andes) said to give fast "kreh-kreh-kreh-kreh-kreh-kreeeenh" and series of "kirrr-wick" calls, different from strident nasal "kryeeeh-nyeh-nyeh-nyeh" of nominate (E of Andes); also louder and more insistent squealing "squée'lee'lee" and "squ'é'é'le'le'le" in disputes. Dawn song loud but simple and clear, slightly reedy and rolled "whée-dic", "pprrri-iu", "chirr-rr" or "cheer chirree", monotonously repeated (once per second), as well as shorter "prriu" or "cheer" punctuated by slurred "bo-oy" or "chrr-ee".
Habitat. Variety of woodland and forest habitats, from humid to arid and deciduous, but most often observed in semi-open areas, savanna and clearings with scattered tall trees, plantations, or edges of more densely covered areas, and drier riparian woodland; in Amazonia usually associated with *várzea* canopy and margins of rivers and lakes, but not exclusively close to water; also shady gardens and tall second growth. Mostly below 1000-1500 m, but often observed to 1850 m (rarely, to 2000 m) in Costa Rica and Panama, and recorded to 1900 m in Venezuela and Ecuador (E Loja).
Food and Feeding. Invertebrates, especially cicadas (Cicadidae) and other very large insects; also known to consume small vertebrates, and figs (*Ficus*), berries and arillate seeds. Usually observed in pairs or small family groups of 3-5 individuals; occasionally joins mixed flocks moving through canopy. Generally at middle to higher levels and often amid dense canopy foliage, but also readily perches conspicuously in the open, on top or at sides of larger trees; sometimes at lower levels, especially on interior branches of more open trees such as *Cecropia*. Scans from perch; sally-gleans prey usually at short distances, from surface of foliage, sometimes hovering briefly, but often striking explosively against leaf; often hammers larger items against perch prior to consumption; rarely, hawks flying insects; fruits and seeds taken by sally-gleaning or perch-gleaning.
Breeding. Feb-Jun in Trinidad; in Colombia, nest-building in Jul and Oct, incubation in Aug in extreme SW (Leticia), males in breeding condition Jun-Aug in N (Guajira, César) and once in Jan in S (Huila); nesting in late Nov in S Brazil, nest-building in Jul in Amazonas; mid-Oct to late Dec (nestlings late Dec) in Argentina (Misiones). Nest, completed in c. 10-14 days, a more or less round and rather shallow cup, composed of variety of materials including twigs, leaves, grass, dry vines, roots, rhizomes of epiphytes, and other fibrous materials, sometimes appearing rather frail and loosely constructed; usually placed at fork of horizontal tree branch c. 6-30 m up, at variable distance (up to 7 m) from trunk. Clutch 2-3 eggs, laid at intervals of 2-3 day; incubation period 17-18 days; nestling period c. 24 days.
Movements. Not very well understood. Some populations of nominate race in S Brazil and NE Argentina considered migratory; also known to wander broadly and appears to undergo some elevational shifts, descending from higher altitudes following breeding season.
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in numerous national parks and other protected areas throughout its very large range. Adaptable: found in wide variety of wooded habitats, and exhibits tolerance of degraded habitats. Not likely to become threatened.

Genus *TYRANNOPSIS* Ridgway, 1905

352. **Sulphury Flycatcher**

Tyrannopsis sulphurea

French: Tyran des palmiers **German**: Schwefeltyrann **Spanish**: Tirano Palmero

Taxonomy. *Muscicapa sulphurea* Spix, 1825, Manaus, Rio Negro, Brazil.
Long considered closely related to *Myiozetetes* on grounds of plumage. More recent evidence relating primarily to syringeal morphology, nest architecture and molecular-sequence data indicates close affinity with, instead, *Megarynchus*; molecular data also provide conflicting but fairly weak evidence for the two being either the sister-group to *Conopias*, or basal to a group including *Conopias* as sister to a well-supported clade containing *Empidonomus*, *Griseotyrannus* and *Tyrannus*, but additional sequence data necessary in order to resolve true affinities among these taxa. Monotypic.
Distribution. E Colombia (S from Meta and Vaupés), E & S Venezuela (SE Sucre S to Delta Amacuro, Bolívar and Amazonas), Trinidad and the Guianas S to E Ecuador (primarily R Napo and R Aguarico, but certainly more widespread), E Peru (Loreto, Ucayali, recorded also Madre de Dios), extreme NW Bolivia (Pando area), and Amazonian Brazil (E to Maranhão, S to Rondônia, S Mato Grosso, Goiás and Tocantins).

Descriptive notes. 19-20·3 cm; 54 g. Has head mostly dusky grey, orange-yellow coronal patch (semi-concealed), darker grey on side of head, indistinct whitish supercilium, more blackish mask through eye; upperparts dull olive-brown; wings plain dark brownish dusky, more brownish and darker than back; tail rather short, blunt, brownish-olive, darker than back; throat whitish, blurry dark grey streaking at side; upper chest white, rest of underparts bright yellow, side of breast and flanks with olivaceous tinge, chest side rather obscurely streaked and washed with grey; iris dark; bill rather short and stubby, black; legs black. Distinguished from *Tyrannus melancholicus* mainly by smaller size, duller overall plumage with much browner upperparts, white throat contrasting with yellow breast and belly, blunter (not notched) and proportionately shorter tail; from somewhat similar *Myiozetetes luteiventris* also by larger size, larger bill, more olive tinge above, less prominent olivaceous flammulation across breast. Sexes alike. Juvenile undescribed. Voice. Often rather noisy and excitable, especially early and late in day (but can remain silent for long periods, occasionally interrupted by energetic bursts of vocalization). Calls variable, commonly an electrified screeching "shréééééééé, shr-shréééééééé" or "squeezrr-squeezr-squeezrr-prr", partners often counter-calling rapidly; song a similar-sounding loud, sharp, harsh, high pitched "jweez", "jweez-z jweez", "jee-peet", "jee-peeteet, jeepeet", "ks, ks, ks, ks-ksi-gay" or "shr'dek, shr'r'r'e'k, shr'dek'dek" with characteristic sputtering quality, has been likened to "pulses of electric energy".
Habitat. Borders of humid forest, savannas, pastures and agricultural areas, also in towns where groves of moriche or buriti palms (*Mauritia*) present; sometimes regarded as a moriche specialist, but not exclusively associated with palm trees. To c. 400 m.
Food and Feeding. Insects; also some fruit, and observed to eat *Virola* arils. Usually solitary, often in pairs, sometimes in small family groups. Perches stolidly and conspicuously in the open at various heights, usually higher up and on tops of trees and bushes. Hawks flying insects, often sallying long distances in pursuit of prey, much like *Tyrannus*; takes fruit by hover-gleaning, often flying long distances to fruiting trees.
Breeding. Apr in Trinidad; birds in breeding condition in Feb and Apr in Colombia (NE Meta). Nest round and cup-shaped, rather frail, loosely composed of sticks, usually placed at base of fronds in crown of palm. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Not well known; generally regarded as resident, with no apparent indication of migratory movements.
Status and Conservation. Not globally threatened. Rare to uncommon and local. Occurs in Tinigua National Park, in Colombia, Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Jatun Sacha Biological Reserve, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Noel Kempff Mercado National Park, in Bolivia, and Jaú National Park and EMBRAPA Experimental Station, in Brazil. Given its large range and tolerance of

converted and disturbed habitats, this species is thought unlikely to become threatened in near future. Extent to which it is dependent on palms requires further study.

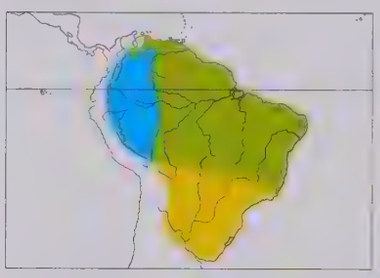
Bibliography. Allen (1995), Bates & Parker (1998), Birdsley (2002), Boesman (1998), Chapman (1894), Clements & Shany (2001), Cory & Hellmayr (1927), Dubs (1992), ffrench (1991), Friedmann (1948), Gilliard (1941), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1998), Herklots (1961), Hilty (2003), Hilty & Brown (1986), Lanyon (1984a), Meyer de Schauensee (1982), Mobley (2002), Parker & Remsen (1987), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1905), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Temple (2002), Tostain *et al.* (1992), Walther (2004).

Genus *EMPIDONOMUS* Cabanis & Heine, 1859

353. **Variegated Flycatcher**

Empidonomus varius

French: Tyran tacheté **German**: Schuppenrücken-Maskentyrann **Spanish**: Tuquito Rayado



Taxonomy. *Muscicapa varia* Vieillot, 1818, Paraguay.

Despite significant differences in plumage, a close but equivocal relationship between present genus, *Griseotyrannus* and *Tyrannus* has been suggested on basis of their shared possession of conspicuous notching on inner webs of outer primaries (an unusual trait, found in only seven or eight distantly related genera in other tyrannid subfamilies); that these three form a monophyletic group was strongly supported in recent analyses of molecular-sequence data. Races differ in migratory behaviour, possibly represent two separate species; further study required. Birds taken from N Venezuela (Carabobo) and E Colombia described as race *septentrionalis*; said to be darker above with heavier streaking below, but indistinguishable from nominate, and presumably relating to migrants from S. Two subspecies currently recognized.

Subspecies and Distribution.

E. v. rufinus (Spix, 1825) - Venezuela (E base of Andes in Portuguesa and Barinas, E Falcón and N cordilleras E to Sucre and Delta Amacuro, also throughout Bolívar and Amazonas), the Guianas and N & E Brazil (E to Pará and SE to Bahia, S along R Madeira to near border with Bolivia).

E. v. varius (Vieillot, 1818) - breeds C & E Bolivia, C & S Brazil (Mato Grosso E to Espírito Santo, S to Rio Grande do Sul), N Argentina (S at least to Tucumán, Santa Fe and Entre Ríos, possibly farther S), Paraguay and Uruguay; S breeders migrate N into range of nominate and NW as far as W Colombia.

Descriptive notes. 18-19 cm; 25 g. Nominate race has mostly blackish or blackish-brown head, yellow coronal patch (semi-concealed), long white supercilia nearly confluent on nape, broad dusky eyestripe, whitish cheekband, conspicuous brownish or dusky malar streak; upperparts largely dusky or dark brownish with decidedly pale whitish streaking, giving somewhat mottled appearance, rump more dark brown with conspicuous rufous margins, uppertail-coverts rufous; wings dusky, prominent white edgings on remiges and wing-coverts; tail rather long, dark brown or blackish, prominent rufous edges; mostly yellowish-white with profuse dusky brown streaking below, throat area more dingy whitish, breast and sides clouded and with streaks rather distinct; iris dark; bill blackish, pale pinkish area at base of lower mandible; legs black. Distinguished from similar *Legatus leucophaius* by longer and proportionately broader bill with pale area at base of lower mandible, paler upperparts with fainter streaking, more conspicuous white edgings on remiges and wing-coverts, rufous edging on rump and tail feathers. Sexes alike. Juvenile is similar to adult, but lacks yellow coronal patch, no streaking on underparts. Race *rufinus* is smaller than nominate, with proportionately smaller bill, wing and tail, paler-looking (brownish, rather than blackish) above, feather margins lighter olivaceous, also with more restricted and less bold streaking below. Voice. Usually rather quiet, even during breeding; harsh "chee-chee-chu" call, final note more prolonged, also a weak (nearly inaudible) high-pitched, thin and nasal "pseee", "zureee" or "zreeetee", usually at rather irregular intervals and sometimes in series; in Brazil voice has been described as high whistled "tsri, si, si, si".

Habitat. Borders of primary forest, secondary woodland, gallery forest, open savanna with scattered bushes and trees, sizable forest clearings, sometimes parks; may also occur in small numbers in *terra firme* forest canopy, but likely only on passage. Mostly below 1200 m, but in Venezuela to 1900 m N of R Orinoco; one record at 3950 m in NC Peru (Ancash).

Food and Feeding. Insects; also small fruits, austral migrants possibly consuming greater quantities of fruit than do residents. Generally solitary; occasionally joins mixed-species flocks, but usually forages independently. Stays rather low or at middle levels on conspicuous exposed perch on small bush or at outer edges of trees, occasionally on top of taller trees; rather erratic and enigmatic in occurrence, with no clear domain, and often observed in unexpected situations. Hawks flying insects, and sallies to hover-glean items from foliage.

Breeding. Nest-building activity recorded as early as mid-Oct (Santo Tomé), eggs late Nov to Dec and nestlings mid-Dec in Argentina. Nest usually like a flattened sphere, composed primarily of smaller twigs and leaf stems, lined with rootlets and leaf ribs, external diameter c. 15 cm, height 7 cm, internal diameter 6 cm, egg-chamber depth 2 cm, weight of one nest 40 g; usually placed c. 1-8 m up in fork of horizontal tree branch. Clutch 2-3 eggs; no information on incubation and fledging periods. Nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. S race (nominate) partially migratory, vacates breeding areas S of E Bolivia and S Brazil. Migrates N primarily into W Amazonia, Venezuela, Trinidad, the Guianas, and intermediate areas in Bolivia and C & N Brazil; austral migrants present throughout much of Colombia (E of Andes) and lowlands of E Ecuador from Mar to Aug, sometimes into late Sept, and in Venezuela mid-Mar to mid-Sept (one record of probable straggler in Táchira in late Oct). S limit of migrant populations not clear; older records exist from La Pampa, La Rioja and San Luis, in Argentina, but these may represent vagrants. Several cases of extreme overshoots in E USA and SE Canada also recorded.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in many national parks and other protected areas. Has a large range and is found in a variety of wooded habitats; tolerant of converted and disturbed habitats. Considered unlikely to be at any risk in the near future.

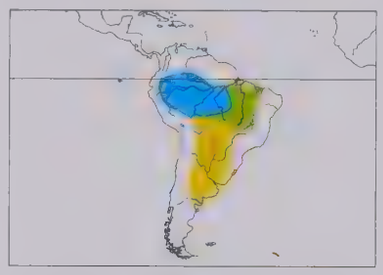
Bibliography. Anon. (1998a), Barrows (1883), Birdsley (2002), Brooks *et al.* (1993), Cabanis & Heine (1859-1860), Canevari *et al.* (1991), Chesser (1997), Cintra (1997), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Contino (1980), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Fjeldså & Krabbe (1990), ffrench (1991), Fitzpatrick (1980c), Friedmann (1927, 1948), Hartert & Venturi (1909), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Ihering (1900), Joseph (1996), Lanyon (1984a), Lowen *et al.* (1996), Meise (1949), Meyer de Schauensee (1966, 1982), Mobley (2002), Narosky & Salvador (1998), Naumburg (1930), Oniki & Willis (1983b), Oren & Parker (1997), de la Peña (1987, 1988), Pinto (1953), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1968), Short (1975), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Tubelis (2000), Walther (2004), Wetmore (1926), Zimmer (1937b).

Genus *GRISEOTYRANNUS* W. E. Lanyon, 1984

354. **Crowned Slaty Flycatcher**

Griseotyrannus aurantioatrocristatus

French: Tyran oriflamme **German**: Grau-Maskentyrann **Spanish**: Tuquito Gris



Taxonomy. *T[yrannus] aurantio-atro cristatus* [*sic*] d'Orbigny and Lafresnaye, 1837, Valle Grande, Santa Cruz, Bolivia.

Despite its very different plumage, was for long placed in genus *Empidonomus* owing to similarities in voice and behaviour; later accorded a monotypic genus based primarily on several apparently uniquely derived differences in syringeal morphology. Molecular-sequence data indicate strong support for *Empidonomus varius* as its closest relative, the two genera constituting a monophyletic group with *Tyrannus*. Two subspecies recognized.

Subspecies and Distribution.

G. a. pallidiventris (Hellmayr, 1929) - EC Brazil (E Pará E to Maranhão and Piauí, S to N Goiás).

G. a. aurantioatrocristatus (d'Orbigny & Lafresnaye, 1837) - breeds N & E Bolivia (S from Beni), WC & S Brazil (S Mato Grosso E to W Minas Gerais, S to Mato Grosso do Sul, extreme W Paraná, Santa Catarina and W Rio Grande do Sul), N & C Argentina (S to Mendoza, La Pampa, N Río Negro and Buenos Aires), Paraguay (especially W of R Paraguay) and Uruguay; migrates N to W Amazonia.

Descriptive notes. 17·5-18 cm; 27 g. Distinctive. Nominate race has rather flat-looking black crown, yellow coronal patch (semi-concealed), grey supercilium, dusky auriculars; upperparts largely dull smoky brownish-grey; wings smoky brown, slight pale edges on inner remiges and wing-coverts; tail long, dull smoky brownish-grey; dingy and uniformly pale smoky brownish-grey below, slightly paler on belly, some yellowish to brownish tinge on belly and undertail-coverts; iris dark; bill rather short, blackish, with short rictal bristles; legs black. Sexes alike. Juvenile resembles adult, but has more brownish crown lack coronal patch, white and more prominent supercilium, pale rusty margins on wing feathers, rufous margins on tail feathers; similar to adult *Empidonomus varius*. Race *pallidiventris* is smaller than nominate, has shorter and less robust bill, paler greyish-olive upperparts, also generally paler below, more yellowish-tinged crissum with very little greyish-brown along shafts. Voice. Generally fairly quiet; when breeding, rather weak "pseek" or high, thin "pseeet", sometimes repeated in series; also thin, buzzy and rising "be-bee-beee-beeez", low whistling "pree-ee-ee-er" and a series of squeaky notes, or a two-part "tsi-tsitsewbit tsitsewt-tsi-tsébidit" phrase, generally considered to be songs. Occasional loud wing rustle, "ewrrrr", reported.

Habitat. Canopy of tall humid forest, lighter woodland, scrubby pastures, and open savannas with some scattered tall trees; austral migrants frequent edges of *terra firme* or *várzea* and clearings within humid forest. Generally at lower elevations, sometimes to 1100 m, but recorded at c. 2000 m in arid intermontane valleys in Boliva; two records at 1600 m and 2500 m in Ecuador (E Loja and W Napo, respectively); once at 2500 m in Venezuelan Andes (Mérida).

Food and Feeding. Insects, also some fruit. Usually solitary, especially migrants in non-breeding season, or in pairs. Regularly perches in the open on top of bushes and trees; sometimes seems rather lethargic. Hawks insects by sallying repeatedly, returning to same well-exposed perch high in canopy.

Breeding. Nests with eggs recorded Nov to early Jan, and nestlings mid-Dec to late Dec/ early Jan. Nest more or less round to oval and cup-shaped, external diameter c. 12-16 cm, height 5-7 cm, often rather flat and loosely constructed, with shallow egg-chamber c. 7-8 cm wide and 3·5 cm deep, composed primarily of smaller twigs (generally c. 2-3 mm thick, occasionally some pieces as large as 10 cm) and leaf stems, lined with rootlets and grass; usually placed in fork of horizontal tree branch c. 2-6 m above ground and often fairly close to trunk, but also as much as 2 m from main bole. Clutch 2-3 eggs, sometimes 4, laid on consecutive days; incubation period c. 15-16 days; nestling period c. 16 days. Nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. S race (nominate) migratory, moving primarily to W Amazonia; recorded in non-breeding season in NE Peru (Loreto, E San Martín), E Ecuador, SE Colombia (Putumayo), Brazil (Acre, Rondônia, Amazonas, and Pará N to Manaus and Belém), extreme S Venezuela (S Amazonas), and probably S Guyana; some records of wanderers from N & W Venezuela (Aragua and NE Mérida). Austral migrants occur in Colombia and Ecuador probably from late Mar to Sept (some may linger to Nov), with specific Jun records from Putumayo, Vaupés and Leticia.

Status and Conservation. Not globally threatened. Generally common and fairly widespread. Occurs in many protected areas. Given its large range and wide habitat preferences, including tolerance of converted and disturbed habitats, this species is unlikely to be at any risk.

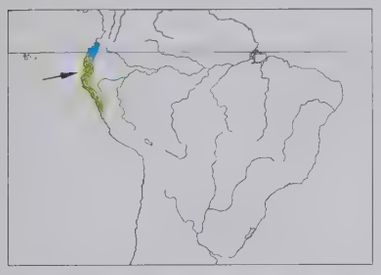
Bibliography. Allen (1995), Barrows (1883), Bates & Parker (1998), Belenguer & Di Martino (1993), Birdsley (2002), Canevari *et al.* (1991), Chesser (1997), Clements & Shany (2001), Contino (1980), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Friedmann (1927), Hartert & Venturi (1909), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Klimaitis & Moschione (1987), Lanyon (1984a), López (1997), Lowen *et al.* (1996), Meyer de Schauensee (1966, 1982), Mezquida (2002), Miserendino (1998), Mobley (2002), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Narosky *et al.* (1990), Naumburg (1930), Nores *et al.* (1983), Pearson (1980), de la Peña (1987, 1988, 1995, 1999), Pérez & Petracci (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1968), Short (1975), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Wetmore (1926), Zimmer (1937b).

PLATE 42 ➤

PLATE 42

inches 4

cm 10



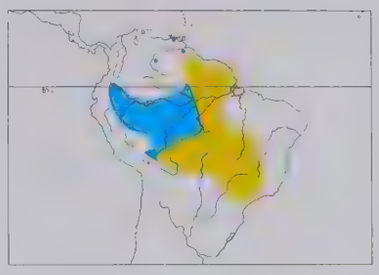
Genus *TYRANNUS* Lacépède, 1799

355. Snowy-throated Kingbird

Tyrannus niveigularis

French: Tyran chimu **German**: Schneekehl-Königstyrann **Spanish**: Tirano Gorginíveo

Taxonomy. *Tyrannus niveigularis* P. L. Sclater, 1860, Babahoyo, Los Ríos, Ecuador.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions; present species appears to be most basal to an expanded "tropical group" that also includes *T. albogularis*, *T. melancholicus*, *T. couchii*, *T. dominicensis* and *T. savana*. Monotypic.
Distribution. Extreme SW Colombia (SW Nariño), W Ecuador (from C Manabí S, including La Plata I, to El Oro and extreme SW Loja) and W Peru (S to Ancash).



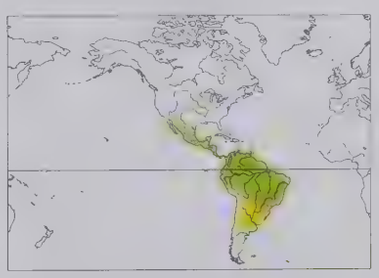
Descriptive notes. 19 cm. Has head largely grey, semi-concealed yellow coronal patch; narrow blackish forehead and blackish band from lores back to auriculars contrast strongly with whitish lower cheeks, creating distinctly masked appearance; upperparts mostly pale grey, becoming more olive on lower back and rump; wings dusky, whitish edging on wing-coverts and inner secondaries; tail nearly blunt-ended, blackish; throat bright white, becoming pale greyish on chest and clear pale yellow on breast and belly; iris dark; bill large, stout, blackish; legs dark. Distinguished from *T. melancholicus* by slightly smaller size, square-ended (not notched) tail, greyer back, whiter throat, paler underparts. Sexes alike. Voice. Short, dry series of "kip" notes, sometimes drawn out into snappy "kip, kr-r-e-e-e", or a thin twittering series.
Habitat. Primarily arid and fairly open country and agricultural areas having scattered groves of trees and bushes; also occurs in semi-open areas with suitable patches of scrub woodland, borders of deciduous woodland, acacia (*Acacia*) in washes, and even coastal desert scrub; sometimes observed in clearings and along edges of humid forest during non-breeding period. To 1200 m, mostly below 500 m; rarely to 1350 m in Ecuador (Mindo).
Food and Feeding. Insects and berries. Perches on tops of bushes, usually in less exposed situations compared with *T. melancholicus*. Hawks flying insects; said also to snatch berries while in flight.
Breeding. Breeds during rainy season, Jan/late Feb to mid-May/July, in SW Ecuador; sometimes double-brooded. Typical nest cup-shaped, c. 8-10 cm in diameter, composed of rather long, thin twigs, dead plant stems and lichen, lined with plant fibres, rootlets and/or hair; usually placed c. 2-8 m up on long, slender branch or stem towards outside of large bush or small isolated tree (live or dead); nest reported as sometimes reused for second breeding attempt. Clutch 3-4 eggs, rarely 2; incubation period estimated at c. 15-16 days and nestling period at c. 14-19 days.
Movements. Sedentary to partially migratory, moving relatively short distances to more humid areas during dry periods; some movement N occurs, and records from SW Colombia and from NW Ecuador N of Manabí probably refer to migrants.
Status and Conservation. Not globally threatened. Uncommon to locally common. Occurs in several national parks and other protected areas, e.g. Cerro Blanco Forest Reserve, Machalilla National Park, Loma Alta Ecological Reserve and Río Palenque Science Centre, all in Ecuador, and Northwest Peru Biosphere Reserve, in Peru. Able to thrive in converted habitat.
Bibliography. Birdsley (2002), Butler (1979), Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Hilty & Brown (1986), Marchant (1960), Meyer de Schauensee (1982), Mobley (2002), Phillips (1994a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Smith (1966), Stotz *et al.* (1996).

356. White-throated Kingbird

Tyrannus albogularis

French: Tyran à gorge blanche **German**: Weißkehl-Königstyrann **Spanish**: Tirano Gorgiblanco

Taxonomy. *Tyrannus albogularis* Burmeister, 1856, Lagoa Santa, Minas Gerais, Brazil.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions; present species may belong to a clade within the "tropical assemblage" that also includes *T. couchii* and *T. savana*, although relationships among these three species uncertain. Monotypic.
Distribution. Breeds from extreme SE Venezuela (SE Bolívar) and the Guianas S through much of C Brazil (Pará, Amapá and Tocantins S to Mato Grosso do Sul, São Paulo, Minas Gerais and W Bahia) to N Boliva (Beni, N Santa Cruz); migrates W across Amazonia (W to extreme SE Colombia, E Ecuador and E Peru).
Descriptive notes. 20-21 cm; 38 g. Has mostly pale grey head, whitish crown with semi-concealed pale orange or yellowish coronal patch; contrasting dusky band from lores back to auriculars, giving distinctive masked appearance; upperparts mostly bright olive-green; wings dull blackish-brown, pale edging on secondaries and margins on wing-coverts; tail rather long, notched, black; throat pure white; underparts bright yellow, very faint (not always obvious) tinge of olive across chest; iris dark; bill large, stout, dark; legs blackish. Distinguished from *T. melancholicus* by slightly smaller size, distinctly paler head, bright olive back, pure white throat and lower cheeks contrasting more with yellow underparts. Sexes alike. Voice. Generally considered less vocal than congeners. Typical call a shrill, trilled "tic tic tic'i'i'i'i'i'i'i'i'i'i'i'i'i"; occasionally long and irregular series of "tic" notes and trills, sometimes for several minutes at a time; similar to *T. melancholicus*, but somewhat higher and thinner, and delivered more rapidly, hence more squeaky in quality.



Habitat. Variety of tropical lowland habitats, such as *cerrado* and savanna, that are fairly open, but shrubby and usually near water; also smaller trees and bushes along edges of gallery woodland, lagoons on river islands, and regularly in stands of moriche palms (*Mauritia flexuosa*) and occasionally *Scheelea* palms. Outside breeding period appears to use wider variety of habitats, including around urbanized areas (especially fence rows), but still usually in close proximity to open water or damp grassland. To c. 1000 m, but mostly below 100 m.
Food and Feeding. Insects. Hawks flying insects from relatively low and exposed perch 3-4 m above ground; may perch higher during breeding period in Brazil.
Breeding. Insufficient information. Apparently builds a simple cup-nest. Seems to be not so aggressive as are its congeners towards other birds.
Movements. Austral migrant; specific movement patterns not well known, probably resident in at least some N parts of range. Migrates during austral winter (approximately May-Aug) into and across W Amazonia, reaching as far as extreme SE Colombia (sight records May to late Aug), E Ecuador (three Jul-Aug records along R Napo) and NE Peru (Loreto, Ucayali); migratory status in Venezuela uncertain, e.g. sight records in Jul in NE Bolívar (El Palmar), Mar in SE Bolívar (San Fernando de Yuruaní) and Feb and Jun in NW Amazonas (Puerto Ayacucho). Sometimes in mixed flocks with *T. melancholicus* during periods of migratory movement.
Status and Conservation. Not globally threatened. Uncommon to locally common; possibly overlooked. Rather poorly known, and precise breeding range uncertain; presumed to breed in small numbers in vicinity of Santa Elena de Uairén, in SE Bolívar (Venezeula), although this not yet formally documented. Occurs in many national parks and other protected areas throughout its range, e.g. Anavilhanas Ecological Station, EMBRAPA Experimental Station and Brasília and Serra da Canastra National Parks, in Brazil, and Beni and Pilón Lajas Biosphere Reserves and Madidi and Noel Kempff Mercado National Parks, in Bolivia. Given its tolerance of converted habitat and its large range, this species does not appear to be at any risk; nevertheless, further study is needed in order to determine its precise ecological and breeding requirements.

357. Tropical Kingbird

Tyrannus melancholicus

French: Tyran mélancolique **German**: Trauerkönigstyrann **Spanish**: Tirano Melancólico
Other common names: Heine's Kingbird ("*T. apolites*")

Taxonomy. *Tyrannus melancholicus* Vieillot, 1819, Paraguay.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Present species formerly treated as conspecific with *T. couchii* owing to limited hybridization in Mexico (S Veracruz, Atlantic slope of N Oaxaca), and possibly intergrades with it, but differs significantly in voice. Furthermore, recent molecular data indicate that these two are not each other's closest relatives, but that present species is sister to *T. dominicensis*, with both nested within an expanded "tropical assemblage" as sister-group to an unresolved clade consisting of *T. albogularis*, *T. couchii* and *T. savana*. In addition, a possible hybrid "*T. apolites*" between present species and *Empidonomus varius* described from Rio de Janeiro area of SE Brazil. Geographical variation over the species' enormous range very inadequately known, and current taxonomy potentially erroneous; race *satrapa* apparently intergrades with nominate. Three subspecies currently recognized.
Subspecies and Distribution.
T. m. satrapa (Cabanis & Heine, 1859) - extreme SW USA (SE Arizona, SW New Mexico, S Texas) and W & E Mexico (both slopes S from Sonora, Tamaulipas and S San Luis Potosí to SE Veracruz and E Oaxaca; also Yucatán Peninsula) S to Panama, N Colombia and much of N Venezuela (mostly N of R Orinoco, also along S bank in NW Bolívar); also Trinidad, Tobago, Grenada and Netherlands Antilles.
T. m. melancholicus Vieillot, 1819 - throughout tropical South America (except N Colombia, N Venezuela and NE Brazil) S to WC Peru (Lima) and, E of Andes, to SE Bolivia and C Argentina (S to Neuquén and NC Río Negro).
T. m. despotes (M. H. K. Lichtenstein, 1823) - NE Brazil (Amapá, Maranhão and Ceará S to Bahia).

Descriptive notes. Male 18·4-24 cm, 32-40·6 g; female c. 18·5-22 cm, 32·7-42·5 g. Male has crown and side of head mostly pale grey, semi-concealed red or orange to reddish-orange coronal patch; dusky lores and auriculars create masked appearance; upperparts mostly greyish-olive or greenish, uppertail-coverts brownish-black; wings dusky or dull blackish-brown, pale whitish edging on secondaries, dull grey margins on wing-coverts; outer five primaries with distinctly attenuated tips (c. 10 mm long, 2-3 mm wide); tail rather long, notched, dusky brown or black; whitish on throat, fading to pale grey on foreneck, becoming tinged with pale greyish-olive to yellow-olive on chest, rest of underparts bright yellow; iris dark brown; bill large, fairly stout, black; legs black. Distinguished from very similar *T. couchii* by slightly larger size, more grey (less greenish) back, relatively larger bill, but mainly by voice.

On following pages: 358. Couch's Kingbird (*Tyrannus couchii*); 359. Cassin's Kingbird (*Tyrannus vociferans*); 360. Thick-billed Kingbird (*Tyrannus crassirostris*); 361. Western Kingbird (*Tyrannus verticalis*); 362. Eastern Kingbird (*Tyrannus tyrannus*); 363. Grey Kingbird (*Tyrannus dominicensis*); 364. Loggerhead Kingbird (*Tyrannus caudifasciatus*); 365. Giant Kingbird (*Tyrannus cubensis*); 366. Scissor-tailed Flycatcher (*Tyrannus forficatus*); 367. Fork-tailed Flycatcher (*Tyrannus savana*).

Female is nearly identical to male, but has smaller coronal patch, and only slightly attenuated outer (four) primaries. Immature is similar to adult but duller overall, coronal patch absent or greatly reduced, more whitish throat, buffy or pale cinnamon margins on wing-coverts, cinnamon edges on uppertail-coverts, remiges edged with pale lemon yellow, little or no attenuation of outer primaries. Races are all very similar: *satrapa* has slightly brighter upperparts and whiter throat than nominate; *despotes* smaller than nominate, with narrower chest band and whiter throat. Voice. Similar to *T. dominicensis*, but a softer and less emphatic "pip- pri-pip-pri-pip-pri" or more rapid and twittering "pip-pip-pip-pip"; call in Mexico described as bright and fluid trill, e.g. "tree-e-eer", "tril-il-il-lil-l" or "trri tri-li-lit í-il" (said to be drier and more tinny in W Mexico), or short and bright "si-seep", while characteristic songs a loud and sweet-sounding series of notes that accelerate through later part, "weet weet weet-weet-weet", or broken series of trills and short, bright note followed by liquid trill, "sweeit tri-í-í-í-il". In South America conspicuous dawn song throughout year, heard quite early and often long before first light, consists of short series of "pip" notes followed by rising and twittering "pirririreee"; dawn song of male described as medley of short, clear "pit prrrrr pit pit prrrrr" notes and thin ascending trills or a couple to several short "pip" notes followed by rising twitter. When excited, partners often call back and forth with variety of high twittering "tre'e'e'e'e'e'eip" trills while vibrating wings or during short flights and when alighting. Sharp crackle, likely generated by wings, heard from birds in flight at close range.

Habitat. Wide variety of habitats, often near water. Widespread throughout lowlands in mostly open and semi-arid scrubland with scattered trees, from deserts to arid or wet montane areas; also frequents humid and dry forest borders adjacent to suitable open country, clearings within largely forested areas, thorn-scrub, scrubby woodland, second growth, beach scrub, mangroves, cactus stands, marsh and river edges, agricultural regions, roadsides, and even busy urban areas; in S Texas (USA) breeds primarily in areas of human disturbance, such as golf courses, electric substations and football fields. Lowlands to 1850 m; occasionally to 2400 m in Central America, to 2200 m (rarely 3000 m) in Venezuelan Andes, to 2500 m in Ecuador (once to 2800 m) and Peru, and commonly to 3100 m in cleared areas in Colombia (Cundinamarca).

Food and Feeding. Almost exclusively insectivorous, taking primarily hymenopterans (wasps, bees), dragonflies (Odonata) and butterflies (Lepidoptera); at least some fruit eaten opportunistically, especially during migratory movements. Analysis of 94 prey items taken from stomachs in SE Peru gave: Hymenoptera (ants 37%, bees and wasps 31%); Isoptera (19%); Coleoptera (5%); Hemiptera (3%); and others (5%). Usually solitary. Perches conspicuously, mostly 3 m or higher; sometimes sallies from low perch, such as a fence, but seems to prefer higher perches for foraging (e.g. top of 30-m snag along forest edge); most often above 25 m (less frequently 12-25 m) in Peruvian dry-forest canopy, and at mean height of 8 m in 10-m vegetation on river islands in Amazonia; often perches on wires and buildings near gardens and plazas. Makes impressive, sometimes acrobatic sallies varying from 2 m to more than 30 m; sometimes sallies to ground, foliage or water, and occasionally takes more than one prey item in single sally. Smaller insects consumed on the wing; larger prey items taken back to perch, often beaten against perch before consumption. Often lingers close to flowers and muddy areas to hunt butterflies. Also observed to hawk insects near lights after dark in Brazil. Fruits taken from trees, shrubs, epiphytes and lianas by perch-gleaning or hover-gleaning. Ecologically and behaviourally similar to North American congeners (*T. tyrannus*, *T. verticalis*, *T. vociferans*); considered more of a foraging specialist than sympatric Neotropical flycatchers, primarily aerial hawking (c. 94% of total foraging activity, mean search time of 60 seconds). Sometimes drinks by flying low over water.

Breeding. Mar-Jul in Costa Rica; Apr-Nov in Venezuela (W Apure); Feb (Popayán), Apr-May (Santa Marta) and nest-building in Aug (Anchicayá Valley) and Nov (NE Meta) in Colombia; mostly Apr-Jul in Trinidad, and Feb, Jun and Jul in Tobago; Oct-Jan in Argentina. Nest a broad, shallow, sometimes frail or untidy and bulky bowl or cup, composed of fine dead vines, grasses, weed stems, leaf tendrils and twigs, usually lined with finer materials and sometimes horsehair; generally placed near outside of bush or on more exposed fork towards end of horizontal tree branch, at varying height (1·8-15 m), sometimes low over water; some nests loosely constructed such that eggs visible from below. Potential nest predators frequently mobbed and boldly chased from area, often with some degree of physical contact; tolerates most congeners nesting in close proximity, in Costa Rica said to direct aggression at *T. dominicensis* but not *T. tyrannus*. Clutch 2-3 eggs, in Argentina 2-4 (rarely, 5); incubation by female, period 15·5-17 days; chicks fed by both parents, fledging period 18-19 days. Nests parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. Apparently resident in S USA (S Texas), but at least partially migratory in N Middle America (race *satrapa*). Nominate race migratory in S parts of range, S from E Bolivia and SE Brazil; moves N to Amazonian lowlands, where large flocks May-Sept, overlapping with resident populations throughout much of N South America (Mar-Oct, especially in humid zones of E & S Venezuela), and records of occasional wintering as far N as Netherlands Antilles, also Cuba (at least three records of vagrants); transients may also occur in Ecuador (Jatun Sacha), as numbers observed to increase noticeably from Apr/May. Large-scale movement of N breeders observed mostly below 1000 m, although smaller numbers reported at altitudes above 3000 m; a few, mostly immatures, occur casually along Pacific Coast of North America (N to British Columbia) some time after nesting period over; more regularly in coastal California and offshore islands (Farallon I, Channel Is) but rarely inland; also winters in Baja California (Sept-Mar) and in C Mexico (Distrito Federal) to 2200 m. Vagrant also in NW and NE USA (SE Alaska, Maine). Occurs irregularly during migration on Grenada, some remaining to breed in some years and not occurring at all in others.

Status and Conservation. Not globally threatened. Very common. Estimated global population 200,000,000 individuals. Has extremely large range, the largest of all kingbirds. Has doubtless increased in abundance and range wherever forest has been opened up and where gardens planted in arid zones. N limit of breeding distribution of race *satrapa* has changed slightly over past 60 or so years; first documentation breeding in USA in 1938, near Tucson (Arizona), was followed by reports of breeding pairs at additional localities in the state; by 1980s, however, known regular nesting restricted to lower Santa Cruz Valley. Closer inspection in 1990s resulted in new nesting records from S Texas (where now considered resident), the result of populations spreading N up Gulf coast of Mexico, and revealed extensive breeding throughout SE Arizona.

358. Couch's Kingbird

Tyrannus couchii

French: Tyran de Couch **German**: Texaskönigstyrann **Spanish**: Tirano Silbador

Taxonomy. *Tyrannus couchii* S. F. Baird, 1858, Nuevo León and San Diego, Nuevo León, Mexico. Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Present species formerly treated as conspecific with *T. melancholicus* owing to limited hybridization in Mexico (S Veracruz, Atlantic slope of N Oaxaca), and possibly intergrades with it, but differs significantly in voice. Furthermore, recent molecular data indicate that these two are not each other's closest relatives, but that present species is part of a clade within the "tropical assemblage" that also includes *T. albogularis* and *T. savana*, although relationships among these three remain uncertain. Has been suggested, on basis of similarities in voice and certain aspects of behaviour, that this species may be closest to *T. vociferans*, *T. crassirostris* and *T. verticalis*, although this not supported by molecular data. Finally, probable hybrid with *T. forficatus* reported from New York (USA). N birds said to have longer wing and those from Yucatán Peninsula (proposed as race *chloronotus*) have longer bill than individuals from Guatemala and Belize, but differences insufficient to warrant naming of geographical races. Monotypic.

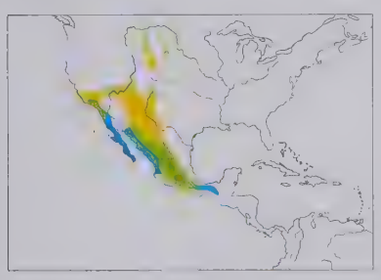
Distribution. Extreme S USA (S Texas), E Mexico (Tamaulipas and N Nuevo León S to NE Oaxaca, N & W Chiapas, and E to Yucatán Peninsula), N Guatemala and Belize.

Descriptive notes. 20-24 cm; 40 g. Male has head mostly grey, small reddish-orange coronal patch (usually concealed), blackish lores and auriculars creating masked appearance; upperparts olive-grey to olive-green (sometimes greyer during breeding); wings blackish-brown or dull buffy brown with slighly paler margins, secondaries with broad yellowish-white outer edges, tertials edged brownish-white, wing-coverts slightly paler than remiges and with pale brownish or greyish margins; attenuated tips of primaries 6-10; tail notched, blackish-brown or dull buffy brown, rectrices with slightly paler margins; chin and throat whitish; underparts yellow, more dusky on breast; iris dark brown; bill large, fairly stout, black or brownish-black, base of lower mandible more brownish; legs black or brownish-black. Distinguished from extremely similar *T. melancholicus* by smaller bill on average, slightly greener (less grey) back, less deeply notched tail, but mainly by voice. Female is like male, but coronal patch smaller and more yellowish-orange, attenuation of primaries less pronounced. Juvenile resembles adult but lacks coronal patch and generally duller, with brownish wash on upperparts, paler yellow underparts, has buff tips on wing-coverts and uppertail-coverts, also more contrasting facial mask, blunt outer primary tips. Voice. Common calls plain and nasal "pit", "kip", "bihk" or "pik", singly or in slowly repeated series, and more distinctive shrill yet buzzy and nasal "pitweeeer", "queer", "chi-querr", "tzheeer", "brrrear" and similar, sometimes in various rolling combinations such as "pik pik pik brreeah". Mated partners give rapid series of slurred "dzh" notes as greeting, usually near nest; male also "tzeeeeerhh" call when guarding nesting territory, and dawn song (from 0·5 hours before twilight until sunrise, mainly Apr-Jun, sometimes also during migration in Sept-Oct) described as series of bright, intensifying whistles with sneezy inflections that ends abruptly, "s'wee s'wee s'wee-i-chu" or "k-leep' k-leep' k-leep' k-leep' k-lee-í-chu", with occasional "brrreeu" sometimes added, or shortened to e.g. "prreeu wi-wit wee wi-chu", "tuwit, tuwit, tuwitichw", etc. Fledglings give distinctive "wheee" begging call. Most calls given throughout year, but seems to be less vocal and sometimes virtually silent during winter months. Sometimes emits bill-snap during chases of avian rivals.

Habitat. Groves of trees, forest edge, shrubby woodland, thorn-forest or tall *chaparral*, brushy clearings within forested areas, plantations, open to semi-open areas with scattered trees and hedges, arid beach scrub, riparian areas, sometimes suburban areas with tall trees; usually near water. Also coastal grassland and scrub during migration. Primarily in lowlands, but recorded to 1000 m in Mexico (Sierra de Tamaulipas).

Food and Feeding. Insects; also fruits. Details of insect prey types taken essentially unknown; in S Texas and Yucatán Peninsula, observed to consume fruits of *Burmelia celastrina*, *Ehretia anacua*, *Condalia hookeri*, *Cissus incisa*, *Magnolia*, *Pyracantha*, *Melia azedarach*, *Sapium sebiferum*, *Busera simaruba*, *Ficus cotinifolia* (probably also *Ehretia tinifolia* and *Metopium brownii*). Most often singly or in pairs, but may join conspecific flocks of 5-50 individuals during migration or in winter; may also mingle with various other bird species, mostly medium-sized passerines, but also Golden-fronted Woodpecker (*Melanerpes aurifrons*) and Red-billed Pigeon (*Columba flavirostris*), primarily in winter or at fruiting trees. Primarily hawks flying insects from a tall and well-exposed perch, including trees, tall bushes and utility wires; usual hawking distance c. 3-15 m, but sometimes as much as 25-30 m; often, but not always, returns to same perch after pursuing prey. Also hover-gleans and perch-gleans fruit, especially during autumn and winter months.

Breeding. Breeds Mar-Aug; nest-building observed mid-Apr to mid-Jul and eggs early May to early Jun in S Texas (lower Rio Grande Valley); eggs early Apr to late Jul in Mexico. Nest-showing display thought to be pair-maintenance behaviour. Nest may be built entirely by female, taking more than 1 week; untidy cup or bowl with outside diameter 15 cm, height 5 cm, inside diameter 7·5 cm, depth 3 cm, composed primarily of twigs and usually with lining of fine rootlets, occasionally of moss and bark strips lined with plant down; usually placed in full sun 6-10 m up (recorded as low as 3 m) or c. 3 m from top of crown and attached to 3-4 thin branches about half-way between centre and outer edge of isolated tree along forest border; variety of nesting trees in S Texas, including *Celtis laevigata*, *Ulmus crassifolia*, *Pithecellobium ebano*, *Fraxinus berlandieriana*, and in NE Mexico once *Populus deltoides*; also observed to build in top of dead tree or utility pole, often nests in same tree with other species, e.g. *Pitangus sulphuratus*. Aggressive towards potential nest predators or conspecific intruders, usually giving chase for 30-40 m; nest territory seems to be most aggressively defended during earliest periods of nest-building and egg-laying. Clutch usually 2-4 eggs, sometimes 5; incubation thought to be entirely by female, period unknown; chicks fed by



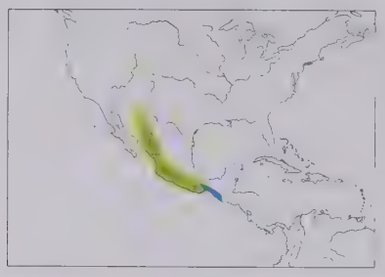
both sexes, nestling period unknown; fledglings thought to be dependent for at least 2 weeks. Parasitized rarely (c. 1 of 18 nests in S Texas) by Bronzed Cowbird (*Molothrus aeneus*), usually rejects eggs but at least occasionally rears parasite's young.
Movements. Probably resident throughout most of range, but at least partially migratory in extreme N. At least some leave S Texas and parts of NE Mexico during Nov-Mar, during which time becomes more numerous in S Mexico, including interior of Chiapas (where otherwise rare or absent in summer); forms loose pre-migratory flocks before leaving rather abruptly. Additional observation necessary in order to clarify seasonal status in S Mexico, where possibly only a winter visitor in N Oaxaca. Vagrant records (late Sept to early May, mainly Nov-Dec) from W, NC & SE Texas, Florida, Arkansas, Louisiana, New Mexico and California.
Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population 1,700,000 individuals. Density at one site estimated at 5·3 territories in 8-ha plot. Sometimes breeds farther NW in Texas; recorded as nesting in Big Bend National Park on at least one occasion. Some evidence suggests that, as with *T. melancholicus*, this species increases in abundance and range wherever closed forest is opened up; numbers increased after large trees were replaced by thorn-scrub.
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bangs & Penard (1921), Bent (1942), Birdsley (2002), Brush (1999a), Conant (1968), Contreras (1997), Cory & Hellmayr (1927), DeSante & Pyle (1986), Fitzpatrick (1980a), Friedmann (1925), Griscom (1950), Howell & Webb (1995a), Kaufman (1996), Lee Jones (2004), Mobley (2002), Oberholser (1974), Phillips (1994a), Price *et al.* (1995), Ridgway (1907), Sennett (1878, 1879, 1884), Smith (1966), Stotz *et al.* (1996), Traylor (1979b), Wauer (1998), Wood *et al.* (1986).

359. Cassin's Kingbird

Tyrannus vociferans

French: Tyran de Cassin **German**: Cassinkönigstyrann **Spanish**: Tirano Gritón

Taxonomy. *Tyrannus vociferans* Swainson, 1826, Temascáltepec, Mexico.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Phylogenetic analyses indicate that present species is basal to a clade including *T. verticalis* and *T. forficatus* within an "E & W species group" that also includes *T. tyrannus* and perhaps *T. caudifasciatus* and/or *T. cubensis*. On basis of similarities in voice and some aspects of behaviour, may be closest to *T. couchii*, *T. crassirostris* and *T. verticalis*, but this not yet supported by molecular data. Validity of race *xenopterus* questionable; further investigation necessary. Two subspecies tentatively recognized.
Subspecies and Distribution.
T. v. vociferans Swainson, 1826 - W & C USA (SE Montana, E Wyoming, SW South Dakota, SW Nebraska, C & S California, extreme SE Nevada, S Utah, SW & SC Colorado, N & E Arizona, New Mexico, W Texas), Mexico (Baja California, and S from W Sonora and Chihuahua to Oaxaca and Chiapas) and Guatemala.
T. v. xenopterus Griscom, 1934 - SW Mexico (highlands of Guerrero).



Descriptive notes. 20·5-23 cm; male 45 g, female 41·4 g. Has dusky grey head, semi-concealed orange-red coronal patch; lores, subocular area, and auriculars only slightly darker than head (faint masked appearance); upperparts mostly dark grey, back strongly washed with olive; wings dark brown with pale brownish margins (looking noticeably paler than back), outer primaries emarginated; tail relatively short, blunt to very slightly cleft, dark brownish-black, narrow buffy to whitish tips; white chin contrasts strongly with dark grey head and dusky grey throat and upper breast, which in turn contrasts sharply with yellow lower breast and belly; iris dark brown; bill relatively short, broad, pointed, mostly black, paler base of lower mandible; legs black or brownish-black. Differs from *T. verticalis* mainly in darker overall plumage, more contrasting white chin, no white on tail side. Sexes essentially alike, female with less extensive coronal patch and less attenuation of tips of outer primaries. Juvenile differs from adult in lacking crown patch, in being duller and slightly more brownish above, with buffy tips on uppertail-coverts and more prominent buffy margins on wing-coverts, generally paler below, and without attenuated tips of outer primaries. Race *xenopterus* is said to be slightly smaller, darker and greyer than nominate. Voice. Quite loud and noisy, vocalizing frequently (males most vocal and frequently counter-call), and with considerable variation in calls; most common call a loud, rough-sounding and curt "sh-beehr", "k-beehrr" or "chi-bew" (accent on second syllable), given throughout year; also rough and nasal "breeahr" or "beeah", repeated, and sometimes followed by sharp, nasal, bickering "ki-dih ki-dih ki-dih" chatter; typical dawn song includes variable series of burry, argumentative notes that climax to emphatic shrieks, "rruh rruh rruh-rruh rreahr, rruh ree ree-uhr" etc., said to resemble somewhat the voice of *Pitangus sulphuratus*. Non-vocal sounds include wing-whir used in agonistic encounters and tumble-flights.
Habitat. Variety of different habitats, including arid to semi-humid and relatively open areas with scattered trees, riparian woodland, oak (*Quercus*) savanna, coastal valleys, grassy bluffs and headlands, sagebrush and mesquite (*Prosopis*) woodland, bushes, hedges, fence rows and utility wires along roads, scrub, parks, irrigated fields, pastures, etc. Generally in thicker vegetation and less open areas than those preferred by sympatric congeners. Sea-level to 3000 m.
Food and Feeding. Primarily insects, also fruits; occasionally spiders, and even small rodents. Stomach contents of birds in C Arizona indicate beetles (Coleoptera) and Hymenoptera (bees, wasps, ants) as most common insect prey; mean size of prey selected by males 8·3 mm, by females 8·8 mm and 8·5 mm; also consumes lepidopteran larvae (both butterflies and moths), grasshoppers (Orthoptera), cicadas (Cicadidae), and even juvenile harvest mice (*Reithrodontonys*). In California stomach contents nearly identical to those of *T. verticalis*, including 14·9% beetles, 21% bees and wasps, 18·2% caterpillars and moths, 14·7% grasshoppers and crickets, 9·1% bugs (Hemiptera), flies (Diptera), dragonflies (Odonata) and spiders; total animal matter 78·6% and vegetable matter 21·4%. Fair amount of fruit eaten, including various Rhamnaceae, grape (*Vitis*), olive (*Olea europea*), elderberry (*Sambucus*), blueberry (*Vaccinium*), also seeds (Ancardiaceae), especially in winter; diet estimated to be almost entirely fruit during Sept-Jan. Captures flying insects mainly by aerial hawking from exposed perch on a tree limb or twig, bush, utility wire or fence. Occasionally forages among shrubs, vines and on the ground; likely gleaning insects directly from vegetation, as suggested by presence of caterpillars in stomach contents. In oak woodland in Sonora (Mexico) during Apr, estimated that 97·8% of total foraging time is spent in sallying activities and 2·2% in probing; perch site a twig 99·4% of time; prey obtained in the air 83·6%, on ground 8·7%, and on foliage 7·7% of the time; 60·7% of time was spent on perches 6·1-9 m high, 25·1% at 3·1-6 m, and 14·2% at 3 m above ground; mean sally distance was 21·6 m, and usually upwards. Mean perch height, sally distance and sally height in SE Arizona varied significantly with habitat type (12 m, 20·1 m and 15 m, respectively, in riparian forest, compared with 7·5 m, 15·8 m and 10·8 m in open woodland); range of heights at which insect prey captured 0-50 m. Time spent perched/watching and sallying for flying insect prey found not to vary significantly with habitat type in SE Arizona (42·6 and 8·1 seconds respectively in riparian forest, 45·9 and 8·7 seconds in open riparian woodland), whereas more variable with respect to habitat type in C Arizona (mean perch time at two different sites c. 39·6 seconds and 54·3 seconds, mean sally time less variable at 5·6 seconds and 4·4 seconds). Food competition with *T. verticalis* in areas of sympatry appears to be minimal, with individuals of each species foraging at least 3 m apart; ecological separation of these species not clear, however, and requires additional study.
Breeding. Generally early/mid-Apr to late Jul/mid-Aug (peak early May to mid-Jul) in SW USA; breeds mid-Mar to Aug in Mexico; possibly two broods occasionally in S Mexico and Guatemala. Partners reinforce pair-bond with vigorous wing-fluttering and tail-spreading displays. Nest built by female, a large, bulky cup-shaped structure, mean outside diameter and height 20 × 7·5 cm, mean inside diameter and depth 8·9 × 4·5 cm, base and walls composed of small twigs, rootlets, weed stalks, strips of inner bark, various other plant fibres, and bits of string, rags, or dry leaves, sides and rim sometimes with feathers or dried flower blossoms, lined with finer rootlets, grass, small feathers, or fluffy cottonwood (*Populus*) seeds; usually placed on top of horizontal branch at variable height (mean 8·9 m in New Mexico, USA) in large dense-canopied tree, including e.g. sycamore (*Platanus wrightii*), cottonwood, willow (*Salix*), oak, walnut (*Juglans*), bluegum (*Eucalyptus*), locust (*Robinia*) and boxelder (*Acer negundo*), also conifer (especially *Pinus*), and yucca (*Yucca*) in arid riparian areas, or on artificial structure (especially utility pole); occasionally nests at same time and in same tree as *T. verticalis*; nest occasionally reused in successive years. Male aggressive towards potential nest predators, various other non-predatory species, and conspecifics that enter territory. Clutch size varies geographically and between years according to insect supply and winter rainfall, estimated mean across range 4·1 (3·3 in Texas, 3·4 in SE Arizona, 4·2 in California); incubation by female, in three studies sitting for 55·4-78·5% of total daylight hours, incubation period probably 15-16 days; chicks brooded by female, fed mostly by female, fledging period probably at least 12-14 days after hatching; juveniles fed by parents for at least 2 weeks. Predation rates in SE Arizona estimated at 3·11 nests lost per 100 days in open riparian woodland and 1·62 nests lost in riparian forest; in all habitats, over 3 years, respectively 32·7%, 54·9% and 29·8% of eggs and nestlings lost to predation. Nest records suggest very rare occurrence of brood parasitism by Brown-headed Cowbird (*Molothrus ater*), but additional study needed.
Movements. Race *xenopterus* sedentary. Nominate race a partial short-distance migrant; wintering range from S California S just barely into W Guatemala. In general, populations in USA and N Mexico move S in autumn to W & S Mexico and parts of Baja California, while some remain in S California, NW Baja California; resident populations persist in C & S Mexico. Post-breeding departure in USA generally late Jul/mid-Aug to end Sept, later (to end Oct) at higher elevations in Texas; return Mar-May. Observations from Sonora indicate that S movements occur mostly Sept-Oct and slow considerably in Nov, and N movement begins mid-Mar and peaks in mid-Apr; transients and wintering birds from N parts of range occur mainly from Sept (earliest migrants recorded Jul) to Apr/mid-May in S Baja California and Pacific slope and adjacent interior of Mexico (S to Oaxaca); non-breeding visitors present in Guerrero (S Mexico) Oct-Apr. Records of vagrants in SE Mexico (SW Campeche), Belize, S Guatemala and C Honduras. Casual during late autumn and early winter well E of breeding range in USA, with records N to E Canada (Ontario) and E to Massachusetts, Virginia and Florida. Migrants sometimes congregate in large flocks, and sometimes mingle with small groups of *T. verticalis*.
Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population at 4,300,000 individuals. USA populations can fluctuate four-fold between years. Survey data show no apparent trend between 1966 and 1996, although local extinctions occurred, possibly related to loss of nesting sites such as large trees, and decrease in amount of insect food brought on by drought cycles.

360. Thick-billed Kingbird

Tyrannus crassirostris

French: Tyran à bec épais **German**: Dickschnabel-Königstyrann **Spanish**: Tirano Piquigrueso

Taxonomy. *Tyrannus crassirostris* Swainson, 1826, Acapulco, Guerrero, Mexico.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. On basis of similarities in voice and certain aspects of behaviour, has been suggested that present species may be most closely related to *T. couchii*, *T. vociferans* and *T. verticalis*; this hypothesis, however, has not yet been evaluated with molecular data. Race *pompalis* weakly differentiated; most recent treatments consider this species to be monotypic. Two subspecies currently recognized.
Subspecies and Distribution.
T. c. pompalis Bangs & J. L. Peters, 1928 - SE USA (extreme SE Arizona, extreme SW New Mexico) and W Mexico (Pacific slope from N Sonora, W Chihuahua, Sinaloa and W Durango S to Colima).
T. c. crassirostris Swainson, 1826 - SW Mexico (Guerrero, Morelos, S Puebla, C Oaxaca, SW Chiapas) and W Guatemala.
Descriptive notes. 20·5-24 cm; 50-60 g. Plumage is mostly greyish-olive to dusky brown above, head darker greyish or dusky brown, semi-concealed yellow coronal patch; nape lighter and more greyish-brown, lores and auriculars somewhat darker grey (slightly masked appearance); wings dark brown, narrow pale cinnamon margins on wing-coverts; tail blunt to very slightly cleft, dark brown, narrow pale cinnamon to rusty-brown edging on rectrices and uppertail-coverts; mostly whitish be-

low, pale dirty grey wash on chest and upper breast, pale lemon-yellow wash on belly and crissum (brighter yellow in fresh plumage); iris dark brown; bill very thick, fairly long, dark grey to black; legs dark grey to black. Sexes similar, but female slightly smaller and usually with less extensive coronal patch. Juvenile is similar to fresh-plumaged autumn adult, but with more greyish-olive head that also lacks coronal patch, darker mask not contrast so much with, more yellowish underparts, buff-cinnamon or rufous margins on wing-coverts, remiges and rectrices. Race *pompalis* is supposedly slightly less olive above and less bright yellow below than nominate, but difference may be due to normal plumage wear. Voice. Typical call a loud, shrill "cur-a-reep" or "kitereer"; other common calls include loud high-pitched "puareet", bright and nasal "di-diweek" or "di-i-diweek", "kidiwik" or "ki-di-wi-eu", and rough and buzzy "chweeer" or "bzzzeiu" repeated numerous times and sometimes mixed with clipped "chk ch-weer" phrases or other nasal or querulous calls; song a choppy nasal series of argumentative notes reaching somewhat more emphatic ending, e.g. "ki-di-di-di di-di-dee-yew". Calls appear to be highly variable, used in different combinations and in variety of contexts. Vocalizes throughout day, but most readily at dawn and early evening; male said to vocalize more frequently than female and to give regularly repeated two-phrase "t t t t t, t t tt rwheeuh t tt" dawn song; also bill-snap noise when agitated.

Habitat. Mostly arid to semi-arid areas with sycamore (*Platanus wrightii*) groves near lowland streams, gallery and tropical deciduous forest, riparian canyons and areas with substantial sycamore, oak (*Quercus*), walnut (*Juglans*), willow (*Salix*), and/or cottonwood (*Populus*), thorn-forest (including *Acacia*, *Bombax*, *Bougainvillea*, *Cassia*, *Ceiba* and *Mimosa*, with canopy at 9-12 m); also woodland edges, clearings within forest, plantations, savanna and semi-open areas with scattered trees, hedges, desert scrub, etc. Mainly sea-level to 1850 m, but up to 2000 m in W Mexico (Sinaloa).

Food and Feeding. Poorly known. Thought to be primarily insectivorous; stomach contents of a single specimen included a large seed, suggesting that fruit consumed at least on occasion. Hawks flying insects from well-exposed perch on top of trees or tall bushes; when in wooded habitat or edges, tends to perch rather high.

Breeding. In S USA, female with fully developed egg in early Jun (SE Arizona) and nest-building observed from mid-Jun (New Mexico); in Mexico mostly early May to Jul, but nesting behaviour observed in late Apr in Morelos. Partners perform wing-fluttering display, especially during nest-building and incubation periods. Nest a rather thin, frail cup, less compact than that of congeners, composed primarily of thin twigs and grass stems that often stick out from edges and above rim (presenting a rather unfinished look), placed openly in crotch of tree branch close to trunk, usually more than 6m (up to 20 m) above ground, but sometimes as low as 1·5 m. Appears to maintain separate territory where sympatric with *T. vociferans*, but territory may overlap with that of *T. melancholicus*; aggression towards *T. verticalis* observed during nesting. Clutch 3-5 eggs, mean 4·25; incubation period c. 16 days; nestling period c. 16-18 days, perhaps longer.

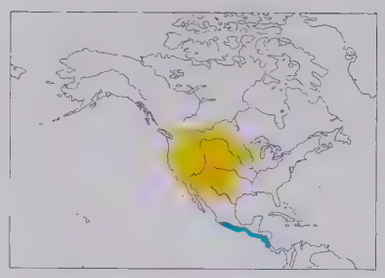
Movements. Populations of race *pompalis* from Arizona, New Mexico and N Sonora said to be at least partially migratory, vacate breeding range early Sept to Oct and return early Apr to early Jun; where these individuals spend non-breeding period is not known. Populations of nominate race apparently winter S to W Guatemala. Details of movements unclear, however, and most populations thought to be resident. Casual in W Arizona, S California, lower R Colorado and Baja California during N autumn and winter. Recorded Sept-Apr on Pacific slope S to W Chiapas. Casual or accidental records N to SW British Colombia (Vancouver I) Oct-Nov.

Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population 2,000,000 individuals. First recorded in USA in 1958, since when slow N expansion; now uncommon but widely dispersed in SE Arizona and SW New Mexico, and locally common, e.g. in Guadalupe Canyon (New Mexico) and Sonoita area (Arizona); also recorded W Texas. North American Landbird Conservation Plan considers this to be "Watch List" species, chiefly because of its restricted distribution in North America; management goal for this species is to maintain or increase current population numbers.

Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bangs & Peters (1928), Birdsley (2002), Blake, E.R. (1953), Blake, E.R. & Hanson (1942), Binford (1989), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), Fitzpatrick (1980a), Gómez de Silva (2002), Hejl *et al.* (1995), Hespenheide (1964), Howell & Webb (1995a), Hutto (1992), Kaufman (1996), Land (1970), Lowther (2002), Mobley (2002), Phillips (1994a), Price *et al.* (1995), Ridgway (1907), Schaldach (1963), Smith (1966), Stotz *et al.* (1996).

361. Western Kingbird

Tyrannus verticalis



French: Tyran de l'Ouest **German**: Arkansaskönigstyrann **Spanish**: Tirano Occidental
Other common names: Arkansas Kingbird

Taxonomy. *Tyrannus verticalis* Say, 1823, near La Junta, Colorado, USA.

Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Phylogenetic analyses indicate that present species and *T. forficatus* form a clade, to which *T. vociferans* is basal, within an "E & W species group" that also includes *T. tyrannus* and perhaps *T. caudifasciatus* and/or *T. cubensis*. Has been suggested, on basis of similarities in voice and certain aspects of behaviour, that it may be closest to *T. couchii*, *T. vociferans* and *T. crassirostris*; but this not yet fully evaluated with molecular data. Monotypic.

Distribution. Breeds in W & C North America (S from S interior British Colombia, S Alberta, Saskatchewan and Manitoba, E to W Minnesota, W Iowa, W Missouri, Oklahoma and Texas) and N Mexico (N Baja California, also S on mainland to S Sonora and NW Chihuahua). Winters from S Mexico (Pacific coast and adjacent interior from S Jalisco and Guerrero to S Chiapas), S Guatemala, El Salvador, SW Honduras and W Nicaragua S to Costa Rica (Terraba region).

Descriptive notes. 19·5-24·1 cm; 35-40 g, male average 38·5 g, female average 37·3 g. Has head and nape pale grey, semi-concealed flame-orange to orange-red coronal patch; dark grey or dusky lores and auriculars create distinctively masked appearance; upperparts ashy greyish-olive, more olivaceous tinge on back and rump; wings rufescent brown to dark brownish-black, pale greyish-white edging on secondaries and wing-coverts; tips of outer primaries attenuated; tail blunt-ended, black, all rectrices with pale brown tips, prominent white lateral margins on outer rectrices; whitish chin and throat, blending to more pale ash-grey on chest and upper breast, rest of underparts bright yellow; wing-lining light yellowish-olive; iris dark brown or hazel; bill relatively short, black,

bluish-black or dark brown; legs bluish-black, dark slate or dark brown. Sexes alike, but female has smaller crown patch, shorter and less attenuated outer primaries. Juvenile is similar to adult but generally paler overall, lacks crown patch, has paler grey head and slightly more greyish-olive back, brownish tinge on breast, paler yellow belly, buff margins on upperwing-coverts, little to no attenuation of outer primaries. Voice. Commonest call a sharp, emphatic "whit", "bec" or "bek"; often emits short bursts of querulous and bickering chatter; song a rapid series of bickering notes that accelerate to short and squeaky chatter, e.g. "pc, pc, pc, pc pc, pc-pc pc, pree pree pr-prrr"; seven vocal patterns identified in adults, variably used in different combinations and in variety of contexts. Nestlings and fledglings beg with short and rapidly repeated wheezing call, also give shorter, fainter "pip-pip-pip" when satiated. Adults usually silent on wintering grounds, but sometimes emit a shrill metallic chatter at communal roosts. Also produces bill-snap in aggressive encounters and "whirring" sound with wings during agonistic interactions.

Habitat. Wide variety of open habitat, including grassland and savanna, sagebrush flats, desert scrub, pasture, agricultural and urban areas that have trees, shrubs or artificial structures (e.g. fence rows and utility wires) suitable for perching; also desert scrub dominated by *Larrea tridentate* and mesquite (*Prosopis*), and riparian areas containing cottonwoods (*Populus fremontii*, *P. sargentii* or *P. deltoides*), sycamore (*Platanus wrightii*) and bordered by desert or pasture, also edges of oak (*Quercus*), pine (*Pinus flexilis* or *P. ponderosa*) and juniper (*Juniperus scopulorum*) woodland. Open country with scattered trees and bushes, pasture, open pine woods and similar, preferred for breeding. In winter also in canopy of open woodland, thorn-forest and plantations. Mostly at lower elevations (below 2120 m) and valleys in montane regions; recorded to 2500 m during migration in W Mexico (Sinaloa).

Food and Feeding. Arthropods (mostly insects) comprise 90-97% of adult diet; principal prey hymenopterans, hemipterans, orthopterans, lepidopteran adults and larvae, dipterans, coleopterans, and spiders; smaller bill size of this species suggests that it takes smaller items than do congeners. Variety of berries also consumed, including those of *Sambucus*, *Crataegus*, *Morus microphylla* and *Psedera*. Feeds primarily on flying insects by aerial hawking from a well-exposed perch, sometimes making very long and acrobatic sallies; also picks insect prey from the ground or sally-gleans it from foliage. Foraging behaviour considerably more flexible compared with other flycatcher species. Large flocks of migrating birds often gather at fruiting trees.

Breeding. Timing of breeding directly related to insect abundance; egg-laying in North America from mid-Apr to Jun, generally later in N; breeds Apr-Aug in Mexico; rarely, two broods. Male performs tumbling aerial display. Nest built by female, taking 4-8 days, an open cup, sometimes bulky, often compact, outside diameter (at top of cup) 14-17·8 cm, height 7-12·7 cm, inside cup diameter 6·4-10·2 cm, depth 5·1-6·4 cm, composed of astounding variety and combination of different materials including small twigs, grass and forb stems, string, bits of plastic and cotton, rootlets, tree bark, cotton and various other plant material, usually lined with wool, hair, feathers, bits of string and cloth, cotton and leaves; placement extremely variable, including natural and artificial structures, most often in tree or shrub and saddled on horizontal branch or wedged in crotch of upward-slanting branch c. 3-17 m above ground, also commonly on utility pole, windmill, antenna, fence post, building or metal girder; some unusual nest-sites include old woodpecker (Picidae) cavity, light fixture in abandoned house, open wooden box, starch box placed on gate post, and rocky cliff; nest tree and immediate vicinity aggressively defended against conspecifics and congeners during incubation period. Clutch 2-7 eggs, average c. 4; incubation by female, period 12-19 days (mean 14 days); chicks brooded for c. 10 days, fledging occurs at c. 16 days; parental provisioning lasts 2-3 weeks. Reports of brood parasitism by Brown-headed Cowbird (*Molothrus ater*) rare.

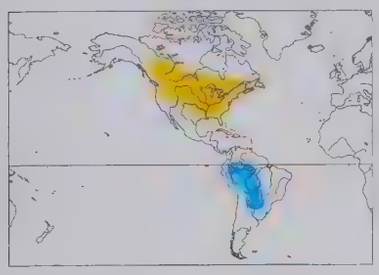
Movements. Medium-distance migrant. Winters mainly from S Mexico S to W Costa Rica, in small numbers also from extreme S USA (regular winter resident in S Florida, and annual records until early Jan along Gulf and Atlantic coast N to Massachusetts). Recorded Sept-Apr on Pacific slope and interior from Guerrero (Mexico) to El Salvador and Nicaragua; winter resident in Costa Rica (mostly Pacific slope) Nov-Apr. Transients occur Apr-May and Aug to early Dec along most of Pacific slope and through interior to S Mexico; also recorded Apr to early May on Atlantic slope N of Isthmus of Tehuantepec. Vagrant recorded on Pacific side of Canal Zone in Panama, but considered casual in Panama; questionable record from Yucatán Peninsula. Migrants very rare, Oct-Nov, in N Bahamas, and vagrants also recorded in Cuba. Casual N to Michigan and Manitoba, and frequent autumn straggler to E North America (S from Maritime Provinces); small numbers regularly in autumn along Gulf and Atlantic coasts from Georgia N to Newfoundland and Nova Scotia. Migrates singly or in small groups, rarely in large flocks; movements appear to be primarily diurnal, but also during late evening and early morning. Often joins overwintering flocks and communal roosts with *T. savana* or *T. forficatus*, especially in W Costa Rica and W Nicaragua, where it appears most numerous.

Status and Conservation. Not globally threatened. Common. Estimated global population 19,000,000 individuals. Breeding densities vary with habitat, from c. 1 pair/3·7 ha in riparian habitat to 1 pair/15 ha in desert; attributed primarily to differences in availability of suitable nest-sites. Has increased in abundance and range over the last 100 years, largely following the opening-up of closed forest, and through human settlements and cultivation bringing vegetation and artificial structures to open areas, e.g. in Great Plains of USA. Survey data indicate that this species increased by 0·9% annually between 1966 and 1994.

Bibliography. Anon. (1998a), Arendt (1992), Baicich & Harrison (1997), Bent (1942), Bergin (1992, 1997), Birdsley (2002), Blancher & Robertson (1987), Campbell *et al.* (1997), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), Fitzpatrick (1980a), Gamble & Bergin (1996), Garrido & Kirkconnell (2000), Hejl *et al.* (1995), Hespenheide (1964), Hiatt (1942), Howell & Webb (1995a), Hutto (1992), Johnsgard (1979), Kaufman (1996), Lee *et al.* (1996), Mackenzie & Sealy (1981), Mobley (2002), Nice (1924), Ohlendorf (1974), Peck & James (1997), Peterjohn *et al.* (1995), Phillips (1994a), Price *et al.* (1995), Raffaele *et al.* (1998), Ridgely & Gwynne (1989), Ridgway (1907), Root (1988), Sauer & Droege (1992), Slud (1964), Small (1994), Smith (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Udvardy (1963), Wetmore (1939), Wiedenfeld *et al.* (1992).

362. Eastern Kingbird

Tyrannus tyrannus



French: Tyran tritri **German**: Schieferrücken-Königstyrann **Spanish**: Tirano Oriental

Taxonomy. *Lanius tyrannus* Linnaeus, 1758, South Carolina, USA.

Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions.

Phylogenetic analyses indicate that present species is basal to a clade including *T. vociferans*, *T. verticalis* and *T. forficatus* within an "E & W species group" that may also include *T. caudifasciatus* and/or *T. cubensis*. W populations of this species sometimes separated (as race *hespericola*) from E ones primarily on basis of differences in lengths of wing, tail and tarsus and in width of white terminal tailband, but considered insignificant. Monotypic.

Distribution. Breeds throughout much of North America, from British Columbia E to Newfoundland, S to N New Mexico, C Texas and S Florida (absent only in Alaska, much of N Canada, and parts of W & SW USA). Winters in South America S to Argentina.

Descriptive notes. 19-23 cm; 40-42 g. Has crown and side of head black, semi-concealed red to orange-red (sometimes yellow) crown patch; often appears slightly crested; upperparts dark slaty blackish-grey; wings blackish-brown, wing-coverts and secondaries with narrow pale grey-white margins (two rather indistinct wingbars); tips of outer two primaries notched and attenuated; tail blunt (somewhat rounded), black, with prominent white terminal band; mostly white below, pale greyish tinge across chest and upper breast; iris dark brown; bill relatively small and short, black; legs dull black. Differs from *T. caudifasciatus* mainly in darker back, more distinct and whiter tailband, whiter belly, proportionately smaller bill. Female slightly smaller, with smaller crown patch, and attenuation only on outermost primary. Juvenile similar to adult but much duller and more pale overall, slightly more brownish-grey above with slight cinnamon edges on nape and rump feathers, pale buffish margins on wing-coverts and outer edges of primaries, darker greyish wash on breast, no crown patch, and little or no white (more pale brown) in tailband, little or no emargination of outer primaries. Voice. Most frequent call a harsh "dzeet" or "zeet", sometimes in series, or high, thin and scratchy "keer"; also series of dry chattering "chatter-zeer" and strident shrill "kip-kip-kipper" or "dzee-dzee"; most complex vocalization a dawn song by male that consists of continuous alternation of two complex phrases, "t't'tzeer, t't'tzeer, t'tzeetzeetzee"; numerous other, mostly high-pitched and rather short calls by both sexes variably used in different combinations and in various contexts; males tend to vocalize more than females. Non-vocal sounds include bill-snap during aggressive encounters, and wing-whirring during chases (likely produced by attenuated tips of primaries). Practically silent when migrating and in wintering areas.

Habitat. Variety of forested and open terrain, including canopy, borders and clearings of open humid forest and semi-open woodland, fields with scattered shrubs and trees, farmland, pastures, orchards, along shelterbelts, parks and golf courses, gardens and towns, and even riparian areas in desert habitat; often near water. May occur in much wider variety of habitats during migration, e.g. marsh-meadow, scrub, dune, and pine forest. In winter mostly river and lake edges; canopy of fruiting trees, but never frequents forest interior. Mostly below 800 m, but as high as 1700 m in Venezuela and highlands of Central America, 2600 m in Colombia during migration, and 3700 m in Ecuador.

Food and Feeding. Primarily flying insects during breeding season; occasionally small vertebrates, such as frogs; also substantial quantities of fruit and arillate seeds, especially during migration and almost exclusively in non-breeding quarters. From analyses of stomach contents, main insect prey (and estimated relative proportions) as follows: Hymenoptera (32·4%), Coleoptera (25·4%), Orthoptera (11·8%), Hemiptera (3·8%), Diptera (3·2%). Fruits and seeds from at least 40 different plant species identified, including *Morus*, *Amelanchier*, *Prunus*, *Rubus*, *Sambucus canadensis* and *Solanum dulcamara*. Flying insects captured by aerial hawking (at a rate of c. 1 predation attempt/minute) from exposed perch c. 1-4 m high (mean 1·3 m, range 0·5-9 m), usually on top of herbaceous plants and small shrubs in fields, but also from fence lines and posts; foraging flight distance averages 2·9 m (range 0·9-7·6 m) and lasts c. 3 seconds; returns to same perch c. 50% of time, with longer sallies more often resulting in change of perch site. Also captures insects from vegetation, ground and sometimes water, by outward and upward striking, perch-to-ground sallies, and hover-gleaning; in absence of suitable perches, will hover in air current and make 10-20 predation attempts in a single flight. On wintering grounds in South America, tends to be dominated by other frugivores and regularly forages with *T. melancholicus* and *T. savana*; large groups of up to thousands of birds often congregate at fruiting trees (especially *Ficus*) during migration or in wintering areas; large numbers congregate in scrub along Caribbean coast of Central America to eat *Cordia curassavica* berries.

Breeding. Late Apr to Aug; timing varies geographically and within populations. Aerial courtship display observed; partners often greet each other with a wing-flutter display. Nest built by female, taking at least 1 week (sometimes over 2 weeks, depending on weather conditions), a relatively large and sturdy open cup, sometimes with rather messy exterior and more elliptical shape, composed primarily of small twigs, coarse roots, dry weed stems, sometimes strips of bark, softer interior of willow (*Salix*) catkins and cottonwood (*Populus*) or cat-tail (*Typhus*) down, often lined with plant down, hair and/or feathers, with occasional incorporation of odd materials such as string, bits of plastic and paper, cigarette butts and even monofilament; average outside diameter 14 cm, height 8·25 cm, inside diameter 7·6 cm, depth 4·5 cm; usually placed openly on horizontal limb c. 0·5-2 m from outside edge of canopy and to more than 20 m above ground (most c. 2-8 m, or c. 2·5 m over water) in variety of tree species, including *Cratageus*, *Ulmus*, mulberry (*Maclura pomifera*), *Picea abies*, cottonwood, oak (*Quercus*), willow, *Acer*, *Gleditsia*, *Carpinus caroliniana*, *Thuja occidentalis* and *Platanus occidentalis*, or often on artificial structure (especially utility pole); also in top of snag, sometimes in depression that nearly creates a cavity, or in crotch close to trunk; old nest occasionally reused, site often reused, and observed to use old nests of *T. forficatus* and oriole (*Icterus*) and to build on top of old nest of American Robin (*Turdus migratorius*). Very vocal and aggressive towards conspecifics and others, with chasing, crouching, tail-spreading, feather-ruffling, but tolerance increases as season progresses and often nests in rather close proximity to heterospecifics, including congeners, without incident. Clutch 2-5 eggs (mode 3, varies geographically), laying begins c. 6 days after nest completed, but may be as little as 2 days or as much as 14 or even 21 days; up to three replacement clutches per season when successive nest failure occurs; incubation by female, period c. 14-17 days; chicks fed by both sexes, nestling period c. 16-17 days; young fed by parents for 3-4 weeks after fledging. Brood parasitism by Brown-headed Cowbird (*Molothrus ater*) occurs, frequency unknown and appears to vary geographically.

Movements. Migratory; winters in South America throughout most of Andes (Colombia S to S Bolivia) and much of Amazonia, S to Paraguay and NW Argentina; occasionally in W & S Venezuela and N Chile (Arica). Largest numbers winter in W Amazonia, Sept-May, most numerous Dec-Feb. Most movements appear to be overland through Central America, although some degree of trans-Gulf movement apparent and likely as primary spring route. Transients occur in E Mexico late Mar/Apr-May and late Aug-Oct; on both slopes in Costa Rica from late Aug/early Sept to late Oct and late Mar to mid-May; in Panama from early Sept to late Nov and late Mar to mid-May, along entire Caribbean slope and Pacific slope (some may overwinter) E from Canal Zone and irregularly in W Panama; in Cuba (including I of Pines), recorded more frequently in W regions Jul-Oct and Mar-Apr, and rarely in E Cuba; also in Cayman Is, N Bahamas, Jamaica, and San Andrés; throughout Caribbean, S-bound migrants appear more common Sept-Oct, while N-bound migrants less frequently recorded Apr-May. Migrants pass through Colombia mostly Sept-Oct and Mar-May and E & NW Ecuador late Sept/Oct-Nov and Mar-Apr/late May, to overwinter primarily in Peru (mainly lowlands E of Andes, rarely in coastal lowlands S to Arequipa), W Brazil and N & E Bolivia; some specimens and numerous sight records of transients in Venezuela, also scattered across Amazonia to the Guianas; smaller numbers S to Chile (S to Valparaiso) and N Argentina (Salta, Tucumán, Formosa, Misiones); a single record from W Bahia (E Brazil). Accidental in Falkland Is; vagrant recorded South Georgia (Nov 1973). Migratory parties from small groups of 5-12 birds to large flocks of several hundreds or even thousands of individuals, which often congregate at night to roost in tall trees, often with other species; larger flocks and more rapid passage more apparent in autumn; a few individuals sometimes mixed with *T. savana* in huge diurnal migrating flocks in Amazonia.

Status and Conservation. Not globally threatened. Common. Estimated global population 13,000,000 individuals. Survey data reveal no apparent trend in breeding numbers between 1966 and 1991, but abundance and trends vary greatly between different US regions; pesticide use, collisions with vehicles, and habitat degradation possibly contribute to negative trends.

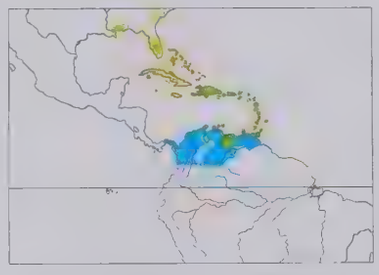
363. Grey Kingbird

Tyrannus dominicensis

French: Tyran gris **German**: Grauer Königstyrann **Spanish**: Tirano Dominicano



Taxonomy. [*Lanius Tyrannus*] *dominicensis* J. F. Gmelin, 1788, Santo Domingo, Dominican Republic.

Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Phylogenetic analyses indicate that present species is sister to *T. melancholicus*, the two nested within an expanded "tropical species assemblage" as sister-group to an unresolved clade consisting of *T. albogularis*, *T. couchii* and *T. savana*. Race *vorax* only weakly differentiated. Two subspecies currently recognized.

Subspecies and Distribution.

T. d. dominicensis (J. F. Gmelin, 1788) - breeds SE USA (SE North Carolina, Georgia, and SE Mississippi to Florida), Bahamas and Greater Antilles, and also locally in NC Venezuela (S to Apure), Trinidad and Tobago, Curaçao, Bonaire, and possibly N Colombia; winters from Panama S to C Colombia and S & E Venezuela.

T. d. vorax Vieillot, 1819 - Lesser Antilles.

Descriptive notes. 21-25 cm; 44-47 g. Dark grey head, crown feathers with dusky shaft streaks, semi-concealed yellow-orange to orange or red coronal patch; dusky lores, subocular area and auriculars (distinctly masked appearance); upperparts mostly pale grey to dark grey, uppertail-coverts blackish with cinnamon edges; wings dusky black or dark brownish, narrow whitish margins on wing-coverts and remiges; tips of outermost primaries slightly attenuated; tail notched, dusky brown or blackish; throat white; underparts whitish, greyish tinge across breast, faint yellowish wash on belly and crissum; iris brown to dark brown; bill large, quite heavy, long, slightly glossy black; legs shiny black. Differs from *T. tyrannus*, *T. caudifasciatus* and *T. cubensis* mainly in grey (not black) head and notched tail. Sexes similar, but female has smaller crown patch. Juvenile resembles adult, but browner above, lacking crown patch, no attenuation of outer primaries, and with brownish or cinnamon margins on wing-coverts, rump and tail. Race *vorax* larger and slightly darker, with larger bill. Voice. Common call emphatic, shrill and rambling "pit-piteerri-ri-ree" or "pitch-chir'r'r're" slightly trilled chatter; also gives shorter, quicker, throaty and rolling "pi-tirr-re" or "pe-cheer-ry" that is more accented on second sylable; trilled "trii-il-il-il" call, reminiscent of that of *T. melancholicus* but harsher; male dawn song a more musical, 6-note variation of call, "pi-ti-réee, pi-ti-rro"; also sharp "peet", "burr" and "tirré". Non-vocal sounds include bill-snapping during courtship and when approaching roosting site, and wing-whirring (function unknown).

Habitat. Primarily dry and open habitats in coastal areas near water, generally avoiding dense forest; also in open forest, open and semi-open areas with scattered trees and bushes, relatively open pine (*Pinus*) and oak (*Quercus*) woodland, areas with scattered *Sabal*, scrub, secondary woodland, edges of mature lowland forest, *llanos*, grassland, farmland, parks, and towns in lowland and cleared montane regions; local in borders of mangroves. Seems to venture farther inland during migration and in wintering areas. Mostly below 500 m; but may occur to 1700 m in Venezuela, and sometimes as high as 2500-3000 m in Andes of Colombia.

Food and Feeding. Wide variety of large flying insects taken, including beetles (Coleoptera), hymenopterans, orthopterans, bugs (Hemipera), flies (Diptera), lepidopterans and dragonflies (Odonata), also arachnids; occasionally small lizards (*Anolis*); also observed to prey on small fish (*Poecilia*); rarely, seen to capture and consume *Eulampis* hummingbirds, perhaps having mistaken them for large insects. Also eats considerable quantities of fruit, including *Roystonea borinquena*, *Xathoxylum*, *Lantana*, *Cordia*, *Etaphrium simaruba* and *Chrysobalanus*. Usually perches conspicuously c. 6-10 m up, rarely lower than 2 m, on top of a bush, bare treetop, fence or telephone wire. Insects taken primarily by aerial hawking (pursuit flights up to 30 m), also hover-gleaned from foliage or the surface of water; sometimes drops to the ground to pursue insect or small lizard. Often returns repeatedly to same perch after sallying, and sometimes bashes prey against perch prior to consumption. Sometimes preys on insects attracted to bright lights in more urban areas. Fruit taken by by hover-gleaning or perch-gleaning. Aggression towards bats (*Molossus molossus*) reported from Cuba, likely as feeding-territory defence.

Breeding. Laying from late May in N of range, from Apr in SE USA (Florida); Mar-Jul in West Indies; females in breeding condition Mar-May and male in May in Colombia; breeds mostly Apr-Jul, occasionally earlier, in Venezuela; sometimes double-brooded. In courtship display, partners cross one another as they ascend straight upwards or in spiralling flight, calling loudly and sometimes snapping bill. Nest cup-shaped, fairly loose and thin, sometimes rather crudely constructed and messy-looking, composed of coarse twigs, stems, vines and marsh grasses, sparse but not particularly soft lining of finer grasses, moss and/or rootlets, and sometimes hair or monofilament; one rather flat nest in Hispaniola had external diameter 24 cm, height 7 cm, internal diameter 8·5 cm, depth 3·5 cm deep; at variable height, generally c. 1-6 m, exceptionally up to 15·2 m (Abaco I), and typically in open and highly exposed setting in fork or saddled on top of horizontal tree branch at varying distance from trunk, in shrub, or sometimes on artificial structure such as telephone pole or lamppost; variety of tree species used, although mangroves seem to be preferred. Both sexes aggressively defend nesting territory against intruders and potential nest predators; very aggressive, regularly attacks mammals of varying sizes and much larger birds. Clutch 2-4 eggs (commonly 3), sometimes 5 (mean 3·25 in Florida, 2·8 in Puerto Rico); incubation period probably c. 14-15 days; chicks leave nest probably at c. 16-18 days, dependent on adults for 3-5 weeks after fledging. Parasitized infrequently, probably not successfully, by Shiny Cowbird (*Molothrus bonariensis*); presumably also by Brown-headed Cowbird (*M. ater*).
Movements. Largely resident from Hispaniola E through Lesser Antilles. Most populations of nominate migrate from Nov, winter mainly in C Panama (late Aug to late Apr) and N South America (mostly early Sept to Apr, rarely early May) from W & N Colombia (S to Valle, Huila and Meta; peak numbers mid-Sept to mid-Oct in Santa Marta) E to Venezuela (fairly common non-breeding visitor, mostly Sept-April, S to N Amazonas and N Bolívar); also, more irregularly, the Guianas and extreme N Brazil (Roraima). Some remain in coastal areas of SE USA and N South America. Transients uncommon to rare on E coast of Yucatán Peninsula and offshore islands from Quintana Roo to Belize in late Mar to Apr and Sept-Nov, probably also N Honduras. Numerous records of casual wanderers N & W of breeding range; single sighting in Ecuador (El Oro). Movements probably diurnal, and migratory flocks typically small, of fewer than 20 individuals.
Status and Conservation. Not globally threatened. Common; one of the commonest and most conspicuous species throughout West Indies; breeding in Venezuela only quite recently recorded, and species may be expanding range. Estimated global population 780,000 individuals. Impact of human activities on this species unclear; some, such as the opening-up of closed forest, may be beneficial, whereas others, e.g. pesticide use, hunting, collisions with vehicles and degradation of coastal habitats, adverse. In general, however, appears to be tolerant of human disturbance.
Bibliography. Anon. (1998a), Arendt (1992), Baicich & Harrison (1997), Barbour (1923, 1943), Bent (1942), Biaggi (1983), Birdsley (2002), Brodkorb (1950), Buden (1987a), Cory & Hellmayr (1927), Cruz & Andrews (1989), Davis (1941), DeGraaf & Rappole (1995), Emlen (1977), Faaborg (1985), Faaborg & Terborgh (1980), ffrench (1991), Fitzpatrick (1980a), García (1987), Garrido & Kirkconnell (2000), Gochfeld (1985), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes & Samad (2002), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Howell *et al.* (1992), Kaufman (1996), Keith (1997), Keith *et al.* (2003), Lee *et al.* (1996), Mobley (2002), Murphy (1989), Paynter (1995), Peterson (1947), Phelps & Phelps (1963), Phillips (1994a), Price *et al.* (1995), Raffaele *et al.* (1998), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Seutin & Apanius (1995), Sick (1993, 1997), Smith, G.A. & Jackson (2002), Smith, W.J. 364. Loggerhead Kingbird

Tyrannus caudifasciatus

French: Tyran tête-police **German**: Olivgrauer Königstyrann **Spanish**: Tirano Guatíbere

Taxonomy. *Tyrannus caudifasciatus* d'Orbigny, 1839, Cuba.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Affinities of present species uncertain; probably closest to *T. cubensis*. Phylogenetic analyses indicate it is either basal to remainder of the ingroup (*Tyrannus* in this case) taxa, or basal to monophyletic "E & W species assemblage" that includes *T. vociferans*, *T. verticalis*, *T. tyrannus* and *T. forficatus*. Races based mainly on insular distribution, but species perhaps better treated as monotypic. Seven subspecies recognized.
Subspecies and Distribution.
T. c. bahamensis (H. Bryant, 1864) - N Bahamas (Grand Bahama, Abaco, Andros, New Providence).
T. c. caudifasciatus d'Orbigny, 1839 - Cuba (including several large cays in Sabana-Camagüey and Jardines de la Reina Archipelago).
T. c. flavescens Parkes, 1963 - I of Pines, off SW Cuba.
T. c. caymanensis (Nicoll, 1904) - Cayman Is.
T. c. jamaicensis (Chapman, 1892) - Jamaica.
T. c. gabbii (Lawrence, 1876) - Hispaniola.
T. c. taylori (P. L. Sclater, 1864) - Puerto Rico (including Vieques).

Descriptive notes. 23 cm. Has blackish head, yellow or pale orange semi-concealed coronal patch; upperparts mostly dark grey, some olive wash on back; wings mostly dark grey, prominent whitish margins on wing-coverts; tail blunt-ended, dark grey, buff-white terminal tips on rectrices; mostly white below, yellow wash on belly and crissum, yellow wash on axillaries; iris dark; bill long and fairly thick, black; legs black. Distinguished from *T. cubensis* mainly by proportionately smaller bill, more conspicuous whitish tail tips, more contrasting head and back. Sexes similar. Juvenile resembles adult, but with brownish wingbars, no crown patch. Races all very similar, differing mainly in amount of yellow wash in plumage, and pattern of tail tip. Voice. Most frequent call a loud, rolling and sputtering "teeerrp" or rising "pit-pit-pit-pit-pit-tirr-ri-ri-reee" chatter.
Habitat. Forests, mangroves and swamp edges.
Food and Feeding. Food primarily larger flying insects, captured by aerial hawking from an exposed perch; also preys on small lizards. Some fruit eaten.
Breeding. Mainly Feb-Jul, also occasionally Nov-Jan; Apr-Jul in Cuba. Nest cup-shaped, composed of twigs, rootlets and sometimes hair, no lining, usually placed in fork of horizontal branch high in tree. Clutch 2-3 eggs, sometimes 4. No other information.
Movements. Resident. Casual wanderer to SE USA (S Florida).
Status and Conservation. Not globally threatened. Common and widespread within range. Apparently from Little Cayman I in recent years. Occurs in several national parks and other protected areas, e.g. Güira National Park, in Cuba.
Bibliography. Anon. (1998a), Barbour (1943), Biaggi (1983), Birdsley (2002), Bond (1928a, 1985), Bradley (2000), Brudenell-Bruce (1975), Cory & Hellmayr (1927), Cruz (1993), Dod (1987), Emlen (1977), Faaborg (1985), Garrido & Kirkconnell (2000), Gundlach (1873), Johnston (1975), Mobley (2002), Parkes (1963), Phillips (1994a), Raffaele (1989), Raffaele *et al.* (1998, 2003), Ridgway (1907), Smith, P.W. *et al.* (2000), Smith, W.J. (1966), Stotz *et al.* (1996), Tossas & Delannoy (2001), Vaurie (1957a), Wetmore & Swales (1931), White (1998).

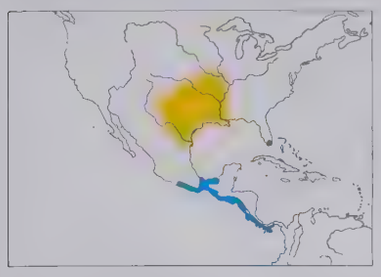
365. Giant Kingbird

Tyrannus cubensis

French: Tyran géant **German**: Riesenkönigstyrann **Spanish**: Tirano Cubano

Taxonomy. *Tyrannus cubensis* Richmond, 1898, Cuba.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Present species probably closest to *T. caudifasciatus*; further styudy required. Monotypic.
Distribution. Locally in Cuba and I of Pines (R Santa Fe).

Descriptive notes. 23-26 cm. Large kingbird with large and almost rounded, flat-looking head. Has blackish crown and nape, orange coronal patch (usually concealed); upperparts mostly dark grey; wings dusky grey; remiges and wing-coverts with narrow but prominent whitish or greyish-white margins; tail slightly notched, dusky, slightly darker than back, rectrices sometimes with pale tips; entirely white below, sometimes pale greyish wash across upper breast; iris dark brown; bill massive, with fairly arched culmen, black; legs blackish. Sexes alike. Juvenile is similar to adult, but lacking coronal patch. Voice. Loud, burry "tooe-tooe-tooee-tooee-toee" chatter, also a call of 4 distinct syllables; also unusual-sounding "antiphonal duet", whereby one member of pair, usually male, begins the song and partner joins in for final notes. Vocalizations often quite loud and far-reaching, sometimes audible over 1-1·5 km. During Feb, vocalizing usually occurs early, during period from c. 15-20 minutes before sunrise to 2-2·5 hours after.
Habitat. Tall lowland forest, especially pine (*Pinus*) forest, and wooded borders of rivers and swamps; also mixed pine barrens with some hardwood trees, open woodland with taller trees, and more open swamp and dry savanna with scattered *Ceiba* trees. Also observed to c. 400 m in cloudforest on serpentine soils in E (mountains SE of Moa); also along riparian corridors in valleys, especially in proximity of coconut palms and other large trees with exposed perches. Said to forage in trees and palms in relatively more open areas during dry season.
Food and Feeding. Appears to have fairly wide diet; feeds primarily on large flying insects (mainly hymenopterans), but also consumes considerable amounts of fruit during dry season; lizards (*Anolis*) and the fledglings and nestlings of other bird species occasionally taken. Usually in pairs at higher levels on an exposed perch in taller trees; compared with congeners seems rather sluggish, and often perches in an almost crouched position, with belly resting on perch. Hawks flying insect, possibly also sally-gleans insects; often tosses larger prey items into air for better orientation and ease of consumption. Fruit usually taken while hovering, occasionally in one location for extended period.
Breeding. Breeds Mar/Apr-Jun; eggs recorded in May. Nest cup-shaped, composed of roots, dried grasses and small twigs, no lining, usually placed high in fork of horizontal branch in large tree (usually, perhaps almost exclusively, *Ceiba pentandra*), once 6 m up in dead and leafless tree surrounded by human and livestock habitations but close to forested area with a stream; breeding territory large, mean 27·5 ha. Clutch 2-3 eggs. No other information.
Movements. Resident.
Status and Conservation. ENDANGERED. Overall population under 1000 birds. In May-Jun of 1999 and 2000, 27 nesting pairs found in Najasa Valley. Occurs naturally in low densities, but appears to be increasingly rare for some as yet unknown reason(s), probably related to habitat loss and degradation of existing habitat through logging and conversion to agriculture. Now extinct in two of the three island groups where it was historically known to occur. Existing populations in Cuba small and widely disjunct. E areas of Alejandro de Humboldt National Park, near Nuevo Mundo, may be a stronghold for the species in E Cuba. Recent records from Pinares de Mayarí; Monte de Regino (Havana province) and El Copey, NE of Caimito (Havana province); and the low-elevation cloudforest SE of Moa, near Trinidad (Sancti Spíritus province). Reported as common in pine forest during middle of 20th century.
Bibliography. Anon. (1998a), Barbour (1923, 1943), Birdsley (2002), Bond (1985), Buden (1987a), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Eisenmann (1955), Faaborg (1985), Garrido & García (1975), Garrido & Kirkconnell (2000), Mobley (2002), Phillips (1994a), Raffaele *et al.* (1998, 2003), Regalado (2002), Ridgway (1907), Rompré *et al.* (2000), Salvin (1889), Smith, P.W. (2001), Smith, W.J. (1966), Stattersfield & Capper (2000), Stotz *et al.* (1996), Suárez (1998).



366. Scissor-tailed Flycatcher

Tyrannus forficatus

French: Tyran à longue queue **Spanish**: Tijereta Rosada
German: Scherenschwanz-Königstyrann
Other common names: Fork-tailed Flycatcher(!)

Taxonomy. *M[uscicapa] forficata* J. F. Gmelin, 1789, Mexico.
Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Present species long considered closest to *T. savana*, mainly due to tail-streamers, and both previously separated in subgenus *Muscivora* (and earlier in genus *Milvulus*); affinity not supported by molecular-sequence data. Phylogenetic analyses indicate clade including this species and *T. verticalis* within "E & W species group" that also includes *T. tyrannus* and perhaps *T. caudifasciatus* and/or *T. cubensis*. Monotypic.
Distribution. Breeds in SC USA (SE Colorado, S Nebraska and SW Missouri S to E New Mexico and W Louisiana) S to NE Mexico (N Coahuila, C Nuevo León, N Tamaulipas). Winters S Mexico

(Atlantic slope from S Veracruz to W Campeche, Pacific slope from Guerrero, and interior Chiapas), El Salvador, Honduras and Nicaragua S to C Costa Rica and rarely W Panama; also S Florida.

Descriptive notes. 19-38 cm including rectrices (c. 11 cm without); 39-40 g. Male has pale grey head, semi-concealed red coronal patch; upperparts mostly pale silvery or pearlescent grey to white, back and rump duller ash-grey with pink tinge; wings mostly dark brown or black, broad whitish edging on wing-coverts and secondaries; outer primaries attenuated (1-3 mm wide) for terminal 19-22 mm; tail deeply forked, mostly blackish, very long outer rectrices basally white or pinkish-white with extensive black terminal sections; mostly pale grey to white below, grey tinge on breast, pink-orange or salmon wash on lower underparts; considerable pink-orange or salmon wash on underwing-coverts, also reddish patch on axillaries (most prominent in flight, sometimes visible around bend of wing when perched); iris dark brown; bill blackish or dark brown, lighter at base, particularly on lower mandible; legs black or dull brown. Female duller overall, pink areas paler, shorter tail, crown patch reduced or absent, outer primaries attenuated for shorter length. Juvenile similar to female but even paler, with duller and more greyish-brown upperparts, paler pinkish wash below, smaller reddish patches on axillaries, little or no attenuation of outer primaries, lacks crown patch and has much shorter tail; adult-like plumage acquired through first winter, but tail remains relatively short in spring. VOICE. Common calls a sharp, dry and harsh "pik", "kip", bik" or "kek", repeated "kee-kee" or "ka-leep", more nasal "bik err", and variations of dry and buzzy chattering; male dawn song consists of varied number of "pup" calls followed by "perleep" or "peroo", also given during aerial display. Non-vocal sounds include dry rustling or wing-whirring heard from flying birds at close range (likely created by attenuated tips of outer primaries), and bill-snapping during aggressive encounters.

Habitat. Open to semi-open and arid to semi-arid brushy scrub and grassland or savanna with scattered trees, second-growth scrub, deciduous forest edge; towns, agricultural areas, pastures, golf courses and parks. More humid areas in winter. Mostly at low elevations, to c. 1500m; to 2300 m in Costa Rica.

Food and Feeding. Major food items include grasshoppers and crickets (Orthoptera), beetles (Coleoptera), hymenopterans, bugs (Hemiptera) and lepidopterans; occasionally flies (Diptera), arachnids, dragonflies (Odonata), mantids and phasmatids. Also somewhat frugivorous, large groups often gathering in trees to consume berries or arillate seeds during migration and in wintering areas. Mostly singly or in pairs during breeding, and in various-sized flocks during migration and on wintering grounds. Feeds primarily on flying insects caught on the wing, usually by aerial hawking from exposed perch (from ground level to 10 m up) in a tree, bush, utility wire or fence; often makes long (up to 60 m) and very graceful sallies in pursuit of prey. Also sally-gleans insects from vegetation, and occasionally directly from the ground, relatively more frequently than do congeners other kingbird species. Reported as foraging at night near streetlights. Drinking from puddles while perched on ground observed on several occasions.

Breeding. Mainly Apr-Aug, occasionally from Mar. Zigzag flight display; strong evidence of assortative mating by tail length reported. Nest a rather thick-rimmed open cup, sometimes with rough exterior and usually more tightly constructed core, composed primarily of coarse materials including plant stems and inflorescences (mostly of *Gnaphalium*), stolons of *Cynodon dactylon*, catkins, also incorporating wool, *Tilandsia usneoides*, *Lepidium*, bits of paper and cloth, string, cotton etc., sometimes with wet soil, caterpillar cocoons, strips of *Juniperus virginiana* bark, feathers, thistle down, even carpet fuzz; lining more tightly woven, of finer material; estimates of average outside diameter 12-15·2 cm, height 5·8-7 cm, inside diameter 7·6-8·2 cm, depth 4·2-5·1 cm; typically placed in fairly exposed situation, with some shading from foliage, at height of up to 8·2 m in small isolated tree or large shrub (at least 20 different tree and shrub species reported as nest-sites), or on utility pole, streetlight or other artificial structure, also sometimes in dead tree; sometimes nests in close proximity to other species, including congeners and even potential predators. Clutch usually 5 eggs, often 4, seldom 3 or 6; relays, rarely up to four times, if breeding attempt fails; incubation by female, period variable, 13-16 days in one study and 13-22 days in another, dependent on date of clutch initiation and weather conditions; chicks fed by both parents, nestling period 14-17 days. Parasitized rarely by Brown-headed Cowbird (*Molothrus ater*).

Movements. Migratory. Winters from SE USA (often small numbers in S Florida), NE, E & S Mexico (Sept-Apr) and Central America S to W Panama; present mainly early Nov to mid-April in Costa Rica, irregular winter visitor Nov-Mar in Panama. Transient migrants occur in E Mexico (Mar-May, Aug-Nov) mainly on Atlantic Slope N of Isthmus of Tehuantepec; uncommon in interior in spring, vagrant in W (mainly Oct-Apr) and in Yucatán Peninsula and Belize(Oct-May). Vagrants also occur in West Indies (late Oct to Dec); abundant records of casual wanderers from numerous localities throughout much of North America. Often roosts in large flocks, often with smaller numbers of other species, during migration and in wintering areas.

Status and Conservation. Not globally threatened. Uncommon to common. Estimated global population 7,900,000 individuals. No apparent overall trend for USA 1966-1994, but significant declines in Oklahoma, Kansas and Arkansas. Variation in abundance between years may be due to predation and adverse weather, e.g. thunderstorms and tornados. Impact of human activities unclear; forest degradation probably beneficial, but offset by pesticide use, collisions with vehicles, and removal of nest-sites in mesquite (*Prosopis*) brush; in general, appears to be tolerant of human disturbance.

Bibliography. Anon. (1998a), Arendt (1992), Baicich & Harrison (1997), Bent (1942), Birdsley (2002), Contreras (1997), Cory & Hellmayr (1927), Davis & Webster (1970), DeGraaf & Rappole (1995), Fitch (1950), Fitzpatrick (1980a), García *et al.* (1997), Garrido & Kirkconnell (2000), González-Guzmán & Mehlman (2001), Howell & Webb (1995a), Johnsgard (1979), Kaufman (1996), McGowan & Spahn (2004), Mobley (2002), Monroe (1968), Nice (1931), Nolte & Fulbright (1996), Ortiz-Pulido (1997), Peer & Sealy (2000), Peterjohn *et al.* (1995), Phillips (1994a), Price *et al.* (1995), Raffaele *et al.* (1998), Regosin (1998), Regosin & Pruett-Jones (2001), Ridgely & Gwynne (1989), Ridgway (1907), Root (1988), Sauer & Droege (1992), Sibley & Ahlquist (1985c), Slud (1964), Smith (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Taylor (1946), Traylor (1977), Traylor & Fitzpatrick (1982), Wetmore (1972).

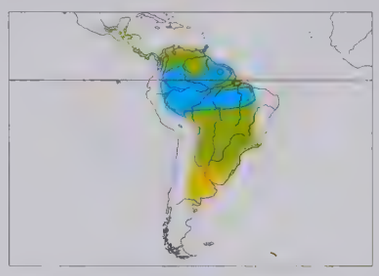
367. Fork-tailed Flycatcher

Tyrannus savana

French: Tyran des savanes **German**: Gabelschwanz-Königstyrann **Spanish**: Tijereta Sabanera

Taxonomy. *Tyrannus savana* Vieillot, 1808, Surinam.

Closest relatives of genus may be *Empidonomus* and *Tyrannopsis*; recent molecular-sequence data indicate present genus is monophyletic and sister-group to clade that includes *Empidonomus* and *Griseotyrannus*; two main clades within genus, loosely corresponding to "tropical species assemblage" and combination of "W" & "E" species groups of earlier authors, but with some exceptions. Present species long considered closest relative of *T. forficatus*, mainly due to tail-streamers, and both previously separated in subgenus *Muscivora* (and earlier in genus *Milvulus*); affinity not supported by molecular-sequence data. Phylogenetic analyses suggest that it belongs to a clade within the "tropical species assemblage" that also includes *T. albogularis* and *T. couchii*, although relationships among these three species remain uncertain. Four subspecies currently recognized.



Subspecies Distribution.

T. s. monachus Hartlaub, 1844 - S Mexico (C & S Veracruz, N Oaxaca, NE Chiapas, Tabasco, SW Campeche) S to Colombia (except N, but generally E of Andes S to Meta and Vichada) and much of Venezuela (E to Orinoco Delta, S to N Amazonas and N Bolívar, and several offshore islands); also S Surinam (Sipaliwini) and NC Brazil (Roraima, lower R Negro, perhaps Amapá).

T. s. sanctaemartae (J. T. Zimmer, 1937) - N Colombia (Caribbean coastal region and Santa Marta Mts area) and extreme NW Venezuela (NW Zulia).

T. s. circumdatus (J. T. Zimmer, 1937) - N Brazil in E Amazonas (occasionally W to Manaus) and Pará and Amapá (S bank R Amazonas, islands near Santarém, and both banks of R Tapajós).

T. s. savana Vieillot, 1808 - C, S & SE Brazil (Rondônia and S Mato Grosso E to Tocantins and S Piauí, S to Mato Grosso do Sul, Minas Gerais, Rio de Janerio and Rio Grande do Sul), N & E Boliva, Paraguay, Argentina (S to Río Negro, occasionally to NE Chubut and even Patagonia) and Uruguay.

Descriptive notes. Male 37-40·5 cm, female 28-30 cm (both including tail); 28 g (*monachus*), 31·5 g (*savana*). Male nominate has most of head and upper nape black (looks black-capped), large semi-concealed yellow coronal patch; upperparts grey, uppertail-coverts black; wings blackish-brown, wing-coverts and secondaries edged pale grey to whitish; tips of outer 2-4 primaries deeply attenuated; tail black, extremely elongated outer rectrices (20-29 cm) basally edged white, outermost rectrices sometimes curving inwards and with slightly twisted tips; entirely white below, underwing-coverts whitish; iris dark; bill and legs blackish. Female generally duller, with shorter tail (elongated outer rectrices c. 14-16 cm), less attenuated outer primaries. Juvenile similar to adult but duller overall, with tail much shorter, head sooty grey, back more brownish, pale cinnamon margins on upper-tail-coverts and wing-coverts, little or no attenuation of outer primaries. Race *circumdatus* is very like nominate; *monachus* has paler grey back, outer primaries deeply notched and with wide tips; *sanctaemartae* differs from previous in having outer primaries almost non-emarginated and with blunt tips. VOICE. Generally rather quiet, even during breeding; thin, low-pitched, weak, rather creaky-sounding "tic", "jek", "tzig" or "jiit" call, sometimes in rapid series and especially in flight; sometimes lower, more emphatic "ek-ek-ek-ek-ek-ek"; also a sharp and slightly liquid "sik" or "plik", as well as various sharp, dry, and clicking or buzzy and rapid chattering notes; alarm an explosive high "jeek" or "dzeep". Male "tzig-tzig-zizizizizi ag ag ag ag ag ag" during aerial display; sometimes also a dry, rattling wing sound, especially from male in courtship display.

Habitat. Open terrain, especially pastures or savanna with scattered trees and bushes; also lawns, residential areas, mangroves, river islands, and along rivers in heavily forested areas; also reedbeds, alders (*Alnus*) and other tall vegetation near water. Can occur in wide variety of habitats during migration, including canopy of tall humid forest. Mostly below 1000 m; transients recorded to 2400 m in highlands of Central America, and in Andes at 2500-3100 m (and to 4100 m in C Peru).

Food and Feeding. Primarily flying insects; considerable quantities of berries and palm fruits also taken outside breeding season. May be observed singly, in pairs or in small family groups; also large flocks during migration and in non-breeding season. Usually perches at lower levels (often 1 m or below) on top of bushes, shrubs, small trees, also fence rows and telephone wires. Insects caught on the wing, usually by aerial hawking from an exposed perch; occasionally catches prey on or close to the ground or water, and frequently makes long and sometimes acrobatic upward sallies in pursuit of prey. Occasionally drops to ground in pursuit of insects. Berries and fruits taken by hover-gleaning or while clinging to cluster of fruits.

Breeding. Breeds Mar-Jun in Costa Rica; Jan-May in Colombia; nests found in Oct in Venezuela (W Apure); Oct-Jan in Argentina. Male display includes spiral flight while calling. Nest a shallow cup composed of plant fibres and leaves, lined with seed down, two in Argentina with external diameter 8-10·5 cm, height 7-9 cm, internal diameter 7-5 cm, depth 5-4 cm; usually placed 1-10 m up in tree or shrub. Clutch 2-3 eggs; incubation period 14-17 days; fledging period 13-16 days. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).

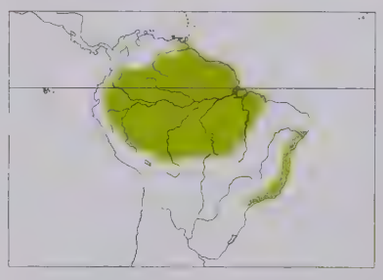
Movements. Resident, nomadic, and partially migratory; migratory in S of range. Movements throughout much of this species' wide range require clarification. N populations resident, with some nomadic and local movements; those farther S in Central America are partially migratory, some reaching N South America (irregular in Venezuela throughout year, some possibly breeding) as far S as N Brazil (Oct-Mar). May be resident in N & W Colombia. S race (nominate) migratory, moving N to N Argentina and S Brazil; present from Mar-Sept/Oct throughout much of Amazonia and throughout the continent to N South America, but primarily E of Andes (perhaps mixed with *monachus* in E Colombia, with peak numbers Nov-Mar), to N coast of Colombia; recorded in E Ecuador from Feb/Mar to Sept; in Venezuela peak numbers late Sept and Mar to mid-Oct, a few groups arriving by first week Feb; also occurs in the Guianas, Trinidad and Tobago. Vagrants casually along Atlantic coast of North America and accidentally inland to upper Midwest and Texas; records of vagrants or overshooting austral migrants from Mexico, N Central America and West Indies, W Ecuador, and coastal areas of Peru and N Chile, also at high altitude in Andes; also casual visitor to Falkland Is. Especially gregarious during migration, large and fairly loose flocks moving at rather high altitudes and often gathering in groups of as many as 5000-10,000 or more to roost at semi-regular spots (e.g. Caroni Swamp, in Trinidad); often mixes with larger numbers of *T. tyrannus*.

Status and Conservation. Not globally threatened. Locally common. Widespread within large range. This species' nomadic nature, coupled with its ability to thrive in a wide range of open habitats with trees, should ensure its survival. Occurs in numerous national parks and other protected areas.

Bibliography. Anon. (1998a), Babarskas *et al.* (2003), Barrows (1883), Bent (1942), Birdsley (2002), Canevari *et al.* (1991), Cavalcanti (1988), Chesser (1997), Cintra (1997), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Cruz & Andrews (1989), Di Giacomo (2004), Faaborg & Terborgh (1980), ffrench (1991), Fitzpatrick (1985a), Fjeldså & Krabbe (1990), Friedman & Smith (1950), Guix (1995), Haffer (1975), Harris (1998), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hayes & Samad (2002), Hilty (2003), Hilty & Brown (1986), Hinojosa *et al.* (1998), Howell & Webb (1995a), Irestedt *et al.* (2001), Johansson *et al.* (2002), Joseph (1996), Kaufman (1996), Keith (1997), Klimaitis & Moschione (1987), Lee Jones (2004), Lockwood (1999), López *et al.* (1989), Lowen *et al.* (1996), Mason (1985), Meyer de Schauensee (1948), Mezquida (2002), Miller (1947), Miserendino (1998), Mlodinow & O'Brien (1996), Mobley (2002), Monroe (1968), Narosky & Salvador (1998), Oren & Parker (1997), Pearson (1980), de la Peña (1987, 1988, 1995), Phillips (1994a), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), do Rosário (1996), Sclater & Salvin (1879), Short (1975), Sibley & Ahlquist (1985c), Sick (1993, 1997), da Silva *et al.* (1997), Slud (1964), Smith (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Traylor (1977), Wetmore (1972), Zimmer (1937b).

Tribe ATTILINI

Genus *RHYTIPTERNA* Reichenbach, 1850



368. Greyish Mourner

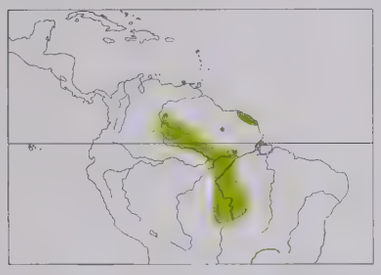
Rhytipterna simplex

French: Tyran grisâtre **German**: Grauschmucktyrann **Spanish**: Plañidera Gris

Taxonomy. *M[uscicapa] simplex* M. H. K. Lichtenstein, 1823, Bahia, Brazil.
Placed by early authors in the family Cotingidae, with supposed close relationship to genera *Laniocera* and *Lipaugus*. Well-supported anatomical evidence, however, indicates that it is a tyrannid, having close affinities to *Sirystes*, *Casiornis* and *Myiarchus*. Two subspecies currently recognized.
Subspecies and Distribution.
R. s. frederici (Bangs & T. E. Penard, 1918) - SE Colombia (S from Meta and Vaupés), E & S Venezuela and the Guianas S to E Ecuador, E Peru, Amazonian Brazil (S to Mato Grosso, N Goiás and N Maranhão) and N Bolivia (S to La Paz, Cochabamba and N Santa Cruz).

R. s. simplex (M. H. K. Lichtenstein, 1823) - E Brazil, from Alagoas S to Minas Gerais and SW São Paulo.

Descriptive notes. 19·5-20·5 cm; 33-38 g. Has plain grey head and upperparts, suggestion of crest on rear crown; wings and tail tinged brownish; underparts slightly paler, light grey on throat, faint yellowish-green tinge on belly; iris dark red to reddish-brown; bill slightly hooked at tip, black, often pink basally; legs black. Distinguished from remarkably similar Screaming Piha (*Lipaugus vociferans*) by smaller size, somewhat paler plumage, redder eyes. Female and presumed immature have some fulvous edging on wing and tail feathers. Race *frederici* is similar to nominate but darker above and on breast. Voice. Loud, fast "r-t-t-t-t-t-t-tchew", sometimes repeated several times in succession or given with 2-3 emphasized notes at end; also a slowly ascending series of clear, whistled "whew" notes.
Habitat. Inhabits middle and upper strata of *terra firme* humid forest, occasionally in transitional forest. Most common below 800 m, but recorded up to 1000 m in SE Peru, and to 1300 m in Venezuela.



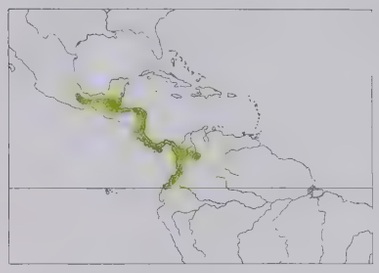
Food and Feeding. Feeds on large insects, also some fruit. Analysis of 19 prey items taken from stomachs in SE Peru, included: Homptera (cicadas 32%); Coleoptera (32%); Orthoptera (16%); Hymenoptera (ants 11%); Lepidoptera (5%); and Dermaptera (4%). Alone, in pairs, or in small group; regularly accompanies mixed flocks. Perches erect, quietly, while peering around in search of prey; then makes sudden sallies to hover-glean from foliage and branches.
Breeding. Male in breeding condition in Aug in Colombia; enlarged gonads Aug-Nov in SE Peru. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Given that much of its habitat remains in relatively pristine condition within its large range, it is not likely to be at any risk. Occurs in many national parks and other protected areas. Status of nominate race in E Brazil, where much forest already destroyed, requires investigation.
Bibliography. Bates & Parker (1998), Begazo (1995), Blake (1950, 1962), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Dubs (1992), Friedmann (1948), Gilliard (1941), Haffer (1974), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon, W.E. (1982b, 1985), Lanyon, W.E. & Fitzpatrick (1983), Lanyon, W.E. & Fry (1973), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Naka (2004), Oren & Parker (1997), Peres & Whittaker (1991), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Silveira *et al.* (2003), Snow, D.W. (1973b), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thiollay & Jullien (1998), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Zimmer (1936a).

369. **Pale-bellied Mourner**

Rhytipterna immunda

French: Tyran à ventre pâle **German**: Hellbauch-Schmucktyrann **Spanish**: Plañidera Pálida

Taxonomy. *Lipaugus immundus* P. L. Sclater and Salvin, 1873, "Oyapoc, Cayenne".
Placed by early authors in the family Cotingidae, with supposed close relationship to genera *Laniocera* and *Lipaugus*. Well-supported anatomical evidence, however, indicates that it is a tyrannid, having close affinities to *Sirystes*, *Casiornis* and *Myiarchus*. Monotypic.
Distribution. Extreme E Colombia, SW Venezuela and Amazonian Brazil (from upper R Negro drainage E to Manaus area, S to Mato Grosso); also S Guyana, Surinam, French Guiana and adjacent NE Brazil (N Amapá).



Descriptive notes. 18·5-19 cm; 28 g. Head and upperparts are dull greyish olive-brown, crown slightly darker; wings duskier, two indistinct pale greyish wingbars, rufous edging on primaries; uppertail-coverts and tail with more brown, rectrices edged rufous, pale edging on outermost pair; greyish below, pale dingy yellowish on belly, flanks tinged rusty; iris brown; bill slightly hooked, blackish, rictal bristles prominent; legs blackish. Differs from rather similar *Myiarchus* species in having rusty flanks, greyer and more rounder head, larger eye. Sexes similar. Voice. Most common call, given at intervals throughout day, a distinctive "pur-treeép, cheeeuu" or "puu-puu-trreeép, cheeeuu" with loud ringing quality; also plaintive "pueeeer"; male infrequently gives leisurely dawn song, "cheeuu purreeéyp cheeuu purreeéyp" and so on.
Habitat. Savanna woodland and borders on sandy soil, scrubby low-canopied *várzea* woodland, and *campinas*; below 300 m.
Food and Feeding. Feeds on insects and some fruit, but not much known. Often perches within 5 m of ground, occasionally much higher. Peers about slowly, searching for prey, and regularly makes short sallies to hover-glean from foliage. Sometimes joins mixed-species flocks.
Breeding. Nothing recorded.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to uncommon and very local; possibly more common, often overlooked. Fairly common at Junglaven Lodge (Amazonas), in Venezuela, and near Powaka and Zanderij, in Surinam. Also occurs at Alechiven Lodge at mouth of R Ventuari, in Venezuela, and in Jaú National Park, in Brazil. The white-sand savanna-like habitat occupied by this species is widespread, and has so far been protected from human exploitation because the soils do not support agriculture.
Bibliography. Cavalcanti (1988), Cory & Hellmayr (1927), Dubs (1992), Forrester (1993), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon, W.E. (1982b, 1985), Lanyon, W.E. & Fitzpatrick (1983), Lanyon, W.E. & Fry (1973), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Ridgely & Tudor (1994), Sick (1993, 1997), Snow, D.W. (1973b), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Zimmer & Hilty (1997).

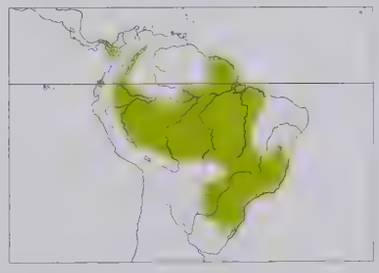
370. **Rufous Mourner**

Rhytipterna holerythra

French: Tyran plaintif **German**: Zimtschmucktyrann **Spanish**: Plañidera Rojiza

Taxonomy. *Lipaugus holerythrus* P. L. Sclater and Salvin, 1860, Choctum, Verpaz, Guatemala.
Placed by early authors in the family Cotingidae, with supposed close relationship to genera *Laniocera* and *Lipaugus*. Well-supported anatomical evidence, however, indicates that it is a tyrannid, having close affinities to *Sirystes*, *Casiornis* and *Myiarchus*. Two subspecies recognized.
Subspecies and Distribution.
R. h. holerythra (P. L. Sclater & Salvin, 1860) - Atlantic slope from S Mexico (N Oaxaca) S to Panama and N Colombia (E to Santander).
R. h. rosenbergi (Hartert, 1905) - Pacific lowlands of W Colombia (S from S Chocó) and NW Ecuador (Esmeraldas).
Descriptive notes. 19·5-21 cm; 36-40 g. Entire plumage is essentially rufous; cinnamon-brown to russet above, crown darker rufous than back; remiges darker brown, broadly edged cinnamon-rufous, contrasting with dusky-tipped primary coverts; tail brighter, more cinnamon-rufous, with darker central feathers; underparts bright cinnamon to ochraceous tawny, often darker with brownish wash on breast; iris dark brown; bill hooked at tip, blackish, base of lower mandible flesh-coloured; legs greyish. Distinguished from superficially very similar but unrelated Rufous Piha (*Lipaugus unirufus*) by smaller size, smaller bill, slightly darker underparts. Sexes similar. Juvenile resembles adult, but perhaps somewhat brighter. Race *rosenbergi* is darker rufous overall than nominate. Voice. Calls include a clear mournful whistle, "wheeeip, wheeeer", and somewhat livelier "wheee-per, wheeéur".

Habitat. Humid evergreen forest and mature secondary woodland, much less often at forest edge; mid-levels and subcanopy. Typically to 1000 m; to 1200 m in Costa Rica.
Food and Feeding. Feeds on large slow-moving insects such as katydids (Tettigoniidae), stick-insects (Phasmida) and caterpillars; also berries and arillate seeds. Often with mixed-species flocks, but also forages alone or in pairs. Lethargic and inconspicuous. Sits for considerable periods on perch; typically hunches far forward while raising its tail; sometimes twists head at odd angles while scanning for prey. Makes sudden sally to snatch prey from foliage; also plucks berries and seeds while in flight.
Breeding. Season Mar-Jun in Costa Rica and Feb-May in Colombia. Nests in tree cavity, usually old woodpecker (Picidae) hole, possibly hole in bank. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally common; perhaps overlooked. Apparently more common in N part of range. Probably locally extinct wherever deforestation has been intense, e.g. in lowlands of Chiriquí (Panama). Occurs in Río Bravo Conservation and Management Area, Columbia River Forest Reserve and Lamanai Archaeological Reserve, in Belize, Laguna del Tigre National Park, in Guatemala, Rancho Naturalista, Tarcol Lodge, Río Negro Jaguar Reserve and Tapantí National Park, all in Costa Rica, and "Jardin Tropical" (near Esmeraldas), Río Palenque Science Centre and Tinalandia Private Reserve (W Pichincha), all in Ecuador.
Bibliography. Anon. (1998a), Binford (1989), Cory & Hellmayr (1927), Cracraft (1985), González-García (1993), Haffer (1974, 1975), Hilty & Brown (1986), Howell & Webb (1995a), Jahn & Mena (2002d), Land (1970), Lanyon, W.E. (1982b, 1985), Lanyon, W.E. & Fitzpatrick (1983), Lanyon, W.E. & Fry (1973), Lee Jones (2004), Lowery & Dalquest (1951), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Smithe (1966), Snow, D.W. (1973b), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Strewe (2000b), Traylor (1977), Wetmore (1972).



Genus *SIRYSTES* Cabanis & Heine, 1859

371. **Sirystes**

Sirystes sibilator

French: Tyran siffleur **German**: Grauschopftyrann **Spanish**: Mosquero Silbador
Other common names: Eastern Sirystes (races E of Andes); Western Sirystes (*albogriseus*)

Taxonomy. *Muscicapa sibilator* Vieillot, 1818, Río Plata, Paraguay.
Affinities obscure. Placed by early authors in the family Cotingidae, but internal morphology (syrinx, nasal capsule) and nesting behaviour indicate that it is allied with "myiarchine" flycatchers in the genera *Rhytipterna*, *Casiornis* and *Myiarchus*. Race *albogriseus* sometimes treated as a separate species, differing in plumage and vocalizations. Five subspecies recognized.
Subspecies and Distribution.
S. s. albogriseus (Lawrence, 1863) - E Panama; NW Colombia (Chocó, E Antioquia, Córdoba) and NW Ecuador (locally in W Esmeraldas, S Pichincha and N Manabí).
S. s. albocinereus P. L. Sclater & Salvin, 1880 - SW Venezuela (W Barinas, Táchira), E Colombia (locally to near base of Andes), E Ecuador, E Peru, W Brazil and N Bolivia (S to La Paz, Cochabamba and N Santa Cruz).
S. s. subcanescens Todd, 1920 - Surinam, French Guiana and E Amazonian Brazil (E to Maranhão, S to Mato Grosso and N Goiás).
S. s. atimastus Oberholser, 1902 - Chapada, in Mato Grosso (Brazil).
S. s. sibilator (Vieillot, 1818) - E & SE Brazil (Goiás and Bahia S to Rio Grande do Sul), E Paraguay (E from Amambay and Paraguarí) and NE Argentina (Misiones, NE Corrientes).

Descriptive notes. 18-18·5 cm; 27·5-36 g. Nominate race has black crown with slight crest, becoming slate-grey on side of head; back mottled olivaceous grey; wings blackish, wing-coverts and inner flight-feathers broadly edged grey; tail long, square, blackish; throat and breast grey, becoming greyish-white on belly; iris dark reddish-brown; bill black; legs blackish. Sexes alike. Juvenile has faint buffy wash throughout. Race *albogriseus* is paler above and below than nominate, has white rump and underparts, two broad white wingbars, white wing edgings, bold white tip on tail; *albocinereus* also has wider area of pure white on rump, but black wings with only narrow white edging, also whiter below; *subcanescens* is similar to nominate but with whitish rump (not so wide as on previous); *atimastus* like nominate, but more extensive yellowish feather tips on rump, pale ashy throat, rest of underparts white. Voice. E of Andes loud ringing "wheer-péw", sometimes lengthened into excited-sounding series, "wheer-pe-pe-pew-pew-péw"; W of Andes a series of huskier notes, "chup-chup-chup" or "prip-prip-prip", sometimes accelerating into chatter.
Habitat. Canopy of forest and mature secondary woodland; frequent in *várzea* and riparian forest in W Amazonia. To c. 1000 m.

On following page: 372. Rufous Casiornis (*Casiornis rufus*); 373. Ash-throated Casiornis (*Casiornis fuscus*).

Food and Feeding. Feeds on fairly large insects; fruits also taken. Often in pairs; follows mixed flocks in forest canopy. Perches in treetops in forward-leaning posture, much like *Myiarchus*; also nods head and raises crown feathers. Frequently hover-gleans or strikes vegetation with downward sallies for prey and small fruits. Seems to forage or wander over large areas.
Breeding. Active nest thought to contain well-developed nestlings in early Oct in SE Peru (Madre de Dios); birds reported in breeding condition in Feb in Panama and Colombia. Peruvian nest was in cavity estimated to be 32 m above ground at base of perpendicular "elbow" in limb of *Calicophyllum* tree, the hole (created from limb breakage, not excavated) running roughly horizontally into main branch; both members of pair seen to attend nest, and to bring insects captured up to 200 m away; intervals between visits averaged 8·6 minutes. No other information.
Movements. Mostly resident; possibly migratory in extreme S Brazil, but seemingly resident in neighbouring E Paraguay.
Status and Conservation. Not globally threatened. Uncommon to fairly common; locally common. In Panama, numerous along Pipeline road in Canal area. Perhaps most abundant in E Paraguay and Brazil where intact forest (especially *várzea* and riparian forest) remains. Race *albogriseus* is red-listed in Ecuador, where it is uncommon and local (perhaps often overlooked), but was reported as common at Limoncocha, near Colombian border. Much of the species' habitat remains in relatively pristine condition within its large range. Occurs in many national parks and other protected areas.
Bibliography. Anon. (1998a), Brooks *et al.* (1993), Canevari *et al.* (1991), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Darrieu (1987), Fitzpatrick (1980c), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Jahn & Mena (2002e), Lanyon, W.E. (1982b, 1984a, 1985), Lanyon, W.E. & Fitzpatrick (1983), Lowen *et al.* (1996), Meyer de Schauensee (1970), Meyer de Schauensee & Phelps (1978), Narosky & Salvador (1998), de la Peña (1988), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), do Rosário (1996), Sick (1993, 1997), Snow, D.W. Genus *CASIORNIS* Des Murs, 1856

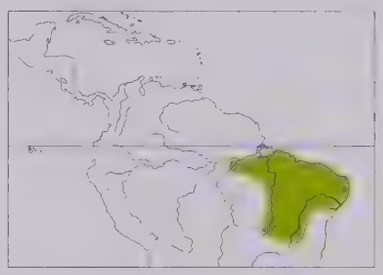
372. Rufous Casiornis

Casiornis rufus

French: Casiorne roux **German**: Zimtrücken-Röteltyrann **Spanish**: Burlisto Castaño

Taxonomy. *Thamnophilus rufus* Vieillot, 1816, Río Plata, Paraguay.
Considered by early authors to belong in the family Cotingidae, but now considered to be allied with the "myiarchine" flycatchers in genera *Rhytipterna*, *Sirystes* and *Myiarchus*. Sometimes treated as conspecific with *C. fuscus*. Monotypic.
Distribution. N & E Bolivia (SE from Beni and La Paz), SC Brazil (S Mato Grosso E to N Goiás and C Minas Gerais, S to Mato Grosso do Sul and São Paulo), Paraguay and N Argentina (S to Tucumán, E Chaco and N Corrientes); also small numbers N to NE Brazil (Maranhão, S Amapá) and W to SE Peru (N to Junín at R Ene) during austral winter.



Descriptive notes. 18 cm; 22-27 g. Plumage is uniform rufous above, somewhat duller on back; throat and breast cinnamon, whitish tinge on mid-throat, belly pale buffy yellowish; iris dark brown; bill dark with fleshy-pink base; legs blackish-grey. Distinguished from similar *C. fuscus* by more uniform rufous above, brighter cinnamon breast, slightly less yellow on belly. Sexes alike. Voice. Surprisingly quiet; sometimes brief, weak "psee" note, occasionally extended into short series.
Habitat. Deciduous and gallery woodland, more heavily wooded *cerrado*, Chaco woodland and scrub; also riparian woodlands and thickets in non-breeding season. Mostly below 1500 m; occasionally in arid inter-montane valleys to 2000-2500 m locally in Bolivia.
Food and Feeding. Perches erect and alert, with crown feathers often raised into bushy crest; sometimes nods head in manner of *Myiarchus*. No other published information; probably sallies for insects.
Breeding. Breeding dates unpublished. Two nests in tree cavity, c. 1·2 and 1·5 m above ground. No other information.
Movements. Little information. Records from Peru and across C Brazil N to Amazon probably relate to austral migrants.
Status and Conservation. Not globally threatened. Fairly common. Much of this species' preferred habitat has been converted for agricultural use and eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations, often encouraged by government incentives. By 1993, two-thirds of *cerrado* region in C Brazil had been heavily or moderately altered; outside protected areas few undisturbed tracts remain, and these could soon be degraded by spreading fires and overgrazing, or could disappear completely through agricultural conversion. Potential effects on this species, however, are little known. Occurs in several national parks and a number of other reserves, both in known breeding range and in non-breeding areas.
Bibliography. Allen (1995), Bates & Parker (1998), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Davis (1993), Di Giacomo (2004), Dubs (1992), Fjeldså & Maijer (1996), Hayes (1995), Joseph (1996), Lanyon, W.E. (1982b, 1984a, 1985), Lanyon, W.E. & Fitzpatrick (1983), López (1997), Lowen *et al.* (1996), Meyer de Schauensee (1982), Miserendino (1998), Narosky & Yzurieta (1993), de la Peña (1988), Perry *et al.* (1997), Ridgely & Tudor (1994), Ridgway (1907), Short (1975), Sick (1993, 1997), Snow, D.W. 373. Ash-throated Casiornis

Casiornis fuscus

French: Casiorne à dos brun **German**: Braunrücken-Röteltyrann **Spanish**: Burlisto Gorgigrís

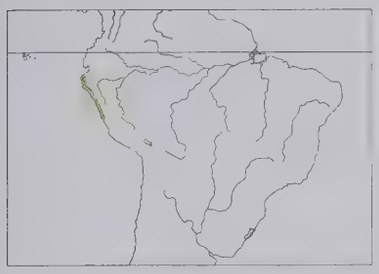
Taxonomy. *Casiornis fusca* P. L. Sclater and Salvin, 1873, Bahia, Brazil.
Considered by early authors to belong in the family Cotingidae, but now considered to be allied with the "myiarchine" flycatchers in genera *Rhytipterna*, *Sirystes* and *Myiarchus*. Sometimes treated as conspecific with *C. rufus*. Monotypic.
Distribution. NE Brazil S of Amazon, from lower R Tapajós E locally to Bélem area and to Paraíba and Pernambuco, and S to NE Mato Grosso (upper R Xingu drainage), N Goiás and NW Minas Gerais.

Descriptive notes. 18 cm; 19·5 g. Plumage is largely rufous above, becoming dull sandy brown on back; wings dusky, broadly edged with rufous to buff, more rufous on shoulders; tail rufous; throat pale greyish, becoming greyish-fawn on breast and pale creamy yellowish on belly; iris dark brown; bill dark, base flesh-pink; legs blackish. Distinguished from similar *C. rufus* by less uniform rufous coloration above, browner back, more dull greyish breast, slightly yellower belly. Sexes alike. Voice. No information.
Habitat. *Caatinga* woodland and more heavily wooded *cerrado*; also *campina* vegetation in lower Amazon region. Recorded up to c. 500 m.
Food and Feeding. Perches erect and alert, with crown feathers often raised into bushy crest. No other published information; probably sallies for insects.
Breeding. No published information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Not well known. Both *caatinga* and wooded *cerrado* subject to increasing human pressure, especially since roads were built in NE Brazil 30 years ago; these habitats are increasingly used for timber and cattle grazing, and are converted for agriculture and tree plantations; uncontrolled fires a problem. Recorded in Cavernas do Peruaçu National Park, in Minas Gerais.
Bibliography. Cory & Hellmayr (1927), Dubs (1992), Forrester (1993), Haffer (1974), Lanyon, W.E. (1982b, 1984a, 1985), Lanyon, W.E. & Fitzpatrick (1983), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Ridgway (1907), Sick (1993, 1997), Snow, D.W. (1973b), Stotz *et al.* (1996), Traylor (1977), Willis & Oniki (1991).

PLATE 44 ➤

PLATE 44

inches 3
cm 8



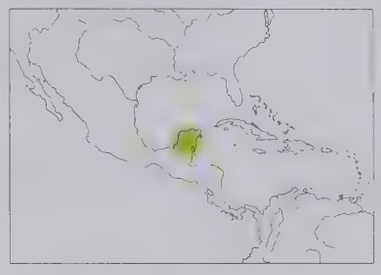
Genus *MYIARCHUS* Cabanis, 1844

374. Rufous Flycatcher

Myiarchus semirufus

French: Tyran roux **German**: Rötelschopftyrann **Spanish**: Copetón Rufo
Other common names: Seaboard Flycatcher

Taxonomy. *Myiarchus semirufus* P. L. Sclater and Salvin, 1878, Pacasmayo, Peru.
Phylogenetic analysis of mitochondrial DNA suggests that this species is either the sister to all others of genus or more closely allied to *Rhytipterna*; in morphology and mtDNA, it is as divergent from present congeners as they are from outgroup taxa. Retention in monotypic *Muscifur* as a subgenus considered not inappropriate. Monotypic.
Distribution. NW Peru, from Tumbes S in narrow coastal zone (generally less than 50 km wide) to near R Pativilca, 200 km N of Lima.



Descriptive notes. 17-19 cm; male 21·7-24 g, female 21-25 g. Distinctive, with plumage predominantly three shades of rufous and brown with no grey or yellow. Head and upperparts brown, rufous uppertail-coverts; throat and underparts nearly uniform light cinnamon-rufous, tending slightly darker on undertail-coverts and tibia, and lighter on chin; brown of upperparts sometimes extends on to side of breast; wings and tail predominantly rufous, lighter and not so rich on wings, wing-coverts mostly rufous but with brown variously on proximal parts of feathers or on inner webs, primary coverts contrastingly darker brown; outer rectrices wholly rufous-brown, remainder with outer webs dark rufous and inner webs dark chocolate-brown with thin outer margin of rufous; underwing-coverts rufous; iris, bill and legs dark; mouth-lining pale orange-yellow. Sexes alike. Juvenile resembles adult. Voice. Dawn song consists of alternated "huit" notes and rasping whistles with a more complex phrase derived from a hiccup note (modified "huit" usually of two syllables, sometimes three) and simple descending whistle frequently interjected. Repeated rasping whistles and hiccups in response to intruding conspecifics; "huit" note and descending whistles uttered occasionally while foraging, presumably as contact call.
Habitat. Tropical and subtropical thorny desert, xerophytic steppes and mesquite savannas; open thorn-woodland dominated by mesquite (*Prosopis*) and acacia (*Acacia*) where trees widely separated by sparse ground cover of grasses and herbs; often in agricultural areas, occasionally in isolated groves in otherwise desolate desert. To 500 m.
Food and Feeding. Apparently no data.
Breeding. Nest with eggs found in Dec and nestlings in May; N populations may breed later than S ones. Two nests described: one an open cup lined with fine coarse fur, fragments of tissue paper, newspaper, clear plastic and a few white feathers, 1 m above ground in darkened recess of large clump of *Acacia macracantha*, other was lined with similar materials but also snakeskin, 14 cm below entrance in tree cavity. Clutch up to 4 eggs; no information on incubation and fledging periods.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Generally uncommon; fairly common in scattered *Acacia-Prosopis* woodlands near Rafán. Arid habitats within Tumbesian region adversely affected by cattle grazing and agriculture in valley bottoms, but overall remain within reasonable state. Despite having a relatively small range, this species is tolerant of converted habitat and is probably not at any risk; it is now rather local, however, because many trees are cut for firewood and are cleared for large-scale farming.
Bibliography. Bangs & Penard (1921), Cory & Hellmayr (1927), Cracraft (1985), Joseph *et al.* (2004), Koepcke (1970), Lanyon, W.E. (1975, 1978, 1985), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Ridgway (1907), Stotz *et al.* (1996), Taczanowski (1884), Todd (1922), Zimmer (1938).

375. Yucatan Flycatcher

Myiarchus yucatanensis

French: Tyran du Yucatan **German**: Yucatanschopftyrann **Spanish**: Copetón Yucateco

Taxonomy. *Myiarchus yucatanensis* Lawrence, 1871, Mérida, Yucatán, Mexico.
Has in the past been suggested as being conspecific with *M. stolidus*, but differs significantly in morphological and vocal characters. Phylogenetic analysis of mitochondrial DNA placed it in a clade with *M. crinitus*, *M. cinerascens* and *M. tyrannulus*. Geographical variation, including populations on Cozumel I (*lanyoni*), seems ecophenotypic (correlated with rainfall and vegetation); nominate race and *navai* apparently intergrade in C Yucatán Peninsula; sampling needed in order to test validity of existing taxonomy. Three subspecies currently recognized.
Subspecies and Distribution.
M. y. yucatanensis Lawrence, 1871 - E Mexico, in extreme E Tabasco (near Balancán) and N & C Yucatán Peninsula.
M. y. lanyoni Parkes & A. R. Phillips, 1967 - Cozumel I, off NE Quintana Roo (Mexico).
M. y. navai Parkes, 1982 - S Quintana Roo (La Vega, Chetumal) and SE Campeche (Xpujil), in Mexico, and Guatemala (Tikal, in N Petén); probably also N Belize (Gallon Jug).
Descriptive notes. 17·5-19 cm; 19-23 g. Unusually rufescent-crowned *Myiarchus* (most populations) with sometimes distinct facial pattern. Nominate race has broad distinctively rufescent edges of dark brown-centred crown feathers (broadest on forecrown), creating streaked appearance; greyish lores and subocular ring; upperparts olive-green, tinged rufous on uppertail-coverts; wings brown, prominent rufous outer edges of primaries, pale greyish-white outer edges of secondaries and tertials, diffuse pale grey tips of greater and median wing-coverts (indistinct wingbars); tail brown, rufous on inner webs of rectrices (often only on innermost rectrices, often reduced or absent on outermost); throat and breast grey, abdomen and undertail-coverts yellow (not sharply demarcated from breast), tending to be washed with olive-green on upper flanks; tibial feathering olive-brown; underwing-coverts yellow; plumage colour recorded as changing rapidly after completion of prebasic moult, thus belly noticeably paler yellow (and mantle browner, tertial edges white, and dark brown of remiges and rectrices faded) in Nov than in Jan-Feb; iris, bill and legs dark, blackish. Distinguished from *M. tuberculifer* by greater amount of rufous in tail. Sexes similar. Juvenile presumably has rufous-tipped wing-coverts. Race *lanyoni* has entire upper surface darker with almost blackish cast, crown with little or no rufescent colour, abdomen paler yellow than nominate; *navai* is intermediate in dorsal coloration between previous and nominate, abdomen also paler yellow than nominate. Voice. Dawn song a fairly loud, clear, monotonously repeated "hoor-eep" or "hoow'eep", second part rising in frequency.

Habitat. Humid to semi-arid forest, scrubby woodland and edge; in deciduous forest found primarily in clearings or thinly wooded areas; in rainforest confined to light second growth and clearings. Sea-level to 250 m.
Food and Feeding. Little known. Hymenopterans recorded in one stomach.
Breeding. Three males with enlarged testes in second half Mar. No other information.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in Lamanai Archaeological Reserve and Río Bravo Conservation and Management Area, in Belize, and Laguna del Tigre National Park, in Guatemala. Population on Cozumel I (race *lanyoni*) has proven surprisingly difficult to locate at times, and concern over its conservation status seems warranted.
Bibliography. Anon. (1998a), Blake, E.R. (1953), Bond (1961b), Chapman (1896), Cory & Hellmayr (1927), Fitzpatrick (1980a), Howell & Webb (1995a), Joseph *et al.* (2004), Land (1970), Lanyon (1965), Lee Jones (2004), Nelson (1904), Parkes (1982), Parkes & Phillips (1967), Paynter (1955), Ridgway (1893, 1907), Smithe (1966), Storer (1961), Stotz *et al.* (1996).

376. Sad Flycatcher

Myiarchus barbirostris

French: Tyran triste **German**: Jamaikaschopftyrann **Spanish**: Copetón Jamaicano
Other common names: Jamaican Flycatcher

Taxonomy. *Tyrannula barbirostris* Swainson, 1827, "Mexico"; error = Jamaica.
Close relationship with *M. tuberculifer* (especially of race *platyrhynchus*) has long been acknowledged. In phylogenetic analysis of mitochondrial DNA, this species found to be most closely related to races *platyrhynchus*, *nigricapillus* and one Ecuadorean sample (identified as *atriceps*) of that species. Responds to playback of *M. tuberculifer* voice, but *platyrhynchus* does not respond to present species. This species should be included in the required taxonomic revision of *M. tuberculifer*. Monotypic.
Distribution. Jamaica.

Descriptive notes. 16·5 cm; 11·5-16·2 g. Relatively small *Myiarchus* with dark crown, broad bill, little or no rufous in tail. Has crown and auriculars smoky olive-brown, contrasting with more olive upperparts; uppertail-coverts olive-brown, tinged rufous; wings brown, little or no prominent clean rufous or cinnamon edging on primaries or secondaries, greyish tips of greater and median wing-coverts often tinged rufous (faint wingbars), tertials edged pale greyish; tail brown, rufous on outermost webs of some rectrices; throat and upper breast grey to pale whitish, abdomen and undertail-coverts lemon-yellow (yellow usually extending anteriorly onto upper breast); tibial feathering olive-brown; underwing-coverts yellow; Iris, bill and legs dark; mouth-lining bright orange. Differs from *M. tuberculifer* (of race *platyrhynchus*) in smaller size, darker crown, browner upperparts. Sexes similar. Juvenile is reported as having no yellow on breast. Voice. Single "huit" note identical to that of *M. tuberculifer*; whistle heard in dawn song not recorded during daylight hours; also emphatic "pip, pip, pip".
Habitat. Primarily lowland and montane evergreen forests and woodland, from sea-level to 2000 m; scarcer in semi-arid lowland areas and more open high-elevation forests, rarely in mangroves.
Food and Feeding. Small insects. Sallies from perches 3-9 m above ground to snatch prey from leaves; often returns to same perch.
Breeding. Few data. Season Apr-Jun. Nest constructed of vegetation, placed in cavity such as woodpecker (Picidae) hole, or under house eaves; recorded as inspecting holes in coconut palms. Clutch 3 or 4 eggs; no information on incubation and fledging periods.
Movements. Range contracts to middle elevations in non-breeding season.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA. Common and widespread. Not known whether recent habitat change has constricted the species' range. In Jamaica, 75% of original forest cover already eliminated, and remaining forest largely second growth; undisturbed forest survives only on high mountain slopes, some of which are protected in the Blue Mountain and John Crow National Park, but hunting and habitat destruction continue because of lack of funds for protection and management. Resurgence in coffee cultivation since 1980s led to clearance of much second growth; other problems include hurricane damage, widespread pesticide use, timber removal, deliberate fires, and continuing conversion for small-scale farming and urbanization.
Bibliography. Anon. (1998a), Bond (1985), Cory & Hellmayr (1927), Faaborg (1985), Joseph *et al.* (2004), Lanyon (1967b), Levy (1996), Pregill *et al.* (1991), Raffaele *et al.* (1998, 2003), Ridgway (1907), Sclater (1871b), Stotz *et al.* (1996).

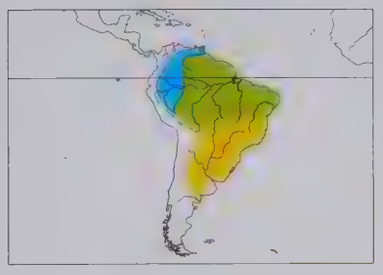
Panama Flycatcher (*Myiarchus panamensis*); 381. Short-crested Flycatcher (*Myiarchus ferox*); 382. Apical Flycatcher (*Myiarchus apicalis*); 383. Pale-edged Flycatcher (*Myiarchus cephalotes*); 384. Sooty-crowned Flycatcher (*Myiarchus phaeocephalus*).

377. Dusky-capped Flycatcher

Myiarchus tuberculifer

French: Tyran olivâtre **German**: Schwarzkappen-Schopftyrann **Spanish**: Copetón Capirotado
Other common names: Olivaceous Flycatcher

Taxonomy. *T[yrannus] tuberculifer* d'Orbigny and Lafresnaye, 1837, Guarayos, Santa Cruz, Bolivia.
Taxonomy highly complex; almost certainly more than one species involved. Phylogenetic analysis of mitochondrial DNA indicates that those Mexican and Panamanian populations examined are more closely related to *M. barbirostris* of Caribbean than to most South American populations of present species; populations of nominate race from Argentina, lowland Ecuador and Guyana formed a well-supported clade. Taxonomic status of *atriceps* particularly doubtful: birds from N extremity of range (Ecuador) found to be closely related to Mexican and Panamanian populations of *platyrhynchus* (*sensu lato*) and *nigricapillus*, whereas those from S extremity (Argentina) were closer to nominate (these findings may be due to introgression, hybridization, faulty taxonomy, or a combination of these factors); further, minor but constant morphological differences in plumage and size exist between N (Ecuador, Peru, N Bolivia) and S populations; molecular diversity in C part of its range in Bolivia should be studied in order to understand patterns of diversity, and to assess the merit of raising *atriceps* to species rank. In addition, races intergrade widely throughout most of species' range, and differences among many of them are at present described in unconvincing and unsatisfactory terms of degrees of shading on dorsal surface. Long-overdue revision needed, with attention paid especially to whether phenotypic variation is clinal and where major disjunctions (if any) occur, the nature of any phylogenetic relationships among races, and the nature of morphological and molecular variation in zones of contact and parapatry; moreover, thorough reassessment of variation in Middle and North American populations required. Thirteen subspecies tentatively recognized.
Subspecies and Distribution.
M. t. olivascens Ridgway, 1884 - breeds SW USA (C & SE Arizona, SW New Mexico) and NW Mexico (NW Chihuahua S in mountains to E Sinaloa, W Durango and N Nayarit); winters W & S Mexico (S Sonora S to Santa Efigenia, in Oaxaca).
M. t. querulus Nelson, 1904 - SW Mexico from S Sinaloa S, including Tres Marías Is, to Oaxaca.
M. t. lawrenceii (Giraud, 1841) - E Mexico (Nuevo Léon S to Tabasco and Chiapas) S to highlands of Guatemala and El Salvador.
M. t. manens Parkes, 1982 - E Mexico (E Tabasco E to Yucatán and Quintana Roo) and N Belize.
M. t. platyrhynchus Ridgway, 1885 - Cozumel I, off NE Yucatán Peninsula.
M. t. connectens W. deW. Miller & Griscom, 1925 - W Belize and Guatemala S to N & C Nicaragua.
M. t. littoralis J. T. Zimmer, 1953 - Pacific coast of Nicaragua and NW Costa Rica.
M. t. nigricapillus Cabanis, 1861 - extreme SE Nicaragua, Costa Rica (except extreme NW) and W Panama.
M. t. brunneiceps Lawrence, 1861 - E Panama (E from Canal Zone) and W Colombia (S through Cauca and Magdalena Valleys to Valle and Huila).
M. t. pallidus J. T. Zimmer & Phelps, Sr, 1946 - NE Colombia and N & W Venezuela.
M. t. tuberculifer (d'Orbigny & Lafresnaye, 1837) - lowland Amazonia (except much of SE), also Trinidad, and SE Brazil.
M. t. nigriceps P. L. Sclater, 1860 - SW Colombia (upper Cauca Valley) S to W Ecuador (S to Guayas and Chimborazo).
M. t. atriceps Cabanis, 1883 - S Ecuador S in Andes to Argentina (S to Tucumán).



Descriptive notes. 15-17 cm; male 16·4-25 g, 18·0-27 g (*atriceps*), male 18-24 g and female 14·2-23 g (combined samples of nominate, *pallidus*, *brunneiceps* and *nigriceps*). Generally smallish *Myiarchus* with dark crown, richly yellow belly. Nominate race has very dark slate-grey to olive-grey crown, variably darker centres of feathers (creating streaked effect on some); face, lores and auriculars not noticeably contrasting with crown; upperparts olive-green, darker olive (approaching colour of crown) on uppertail-coverts; wings brown, little or no pale outer edging on primaries, outer edges of secondaries and tertials respectively pale rufous and greyish-white, greater and median wing-coverts diffusely tipped with greyish cream (indistinct wingbars); tail dull brown, some rufous edging in fresh plumage; throat and breast grey, tending paler on throat, sometimes olive wash on side of upper breast; abdomen and undertail-coverts yellow, tibial feathering olive-brown; underwing-coverts yellow; iris, bill and legs black; inside of mouth orange. Sexes similar. Juvenile has rufous-tipped wing-coverts, rufous outer edges of primaries, rufous edges and tips of rectrices. Races differ mainly in plumage coloration and tone: *pallidus* is paler above, especially on crown, which is a smoky olive; *brunneiceps* resembles nominate, but has greener back; *nigriceps* has noticeably blacker crown, rich yellow belly, sometimes greyish hindcollar; *atriceps* is larger than nominate and with noticeably black pileum, sometimes greyish hindcollar, like previous but larger, belly often paler yellow; *nigricapillus* has back greener, crown less black, rectrices, remiges and wing-coverts fringed, edged or tipped rufous; *connectens* is questionably distinct from previous, but perhaps slightly darker on crown, more strongly washed olive on breast side; *littoralis* has paler crown and upperparts than last two, throat whitish; *lawrenceii* is large, olive-grey above, crown only slightly darker than back, extensive rufous tips and fringes on remiges, rectrices (outer webs) and wing-coverts; *querulus* is questionably distinct from previous, possibly with more rufescent edges of crown feathers, possibly more evident hindcollar (dorsal extension of grey from breast); *manens* is smaller than last, with broader bill, no rufous fringes on rectrices; *platyrhynchus* differs from previous in reportedly whiter (less yellow) underwing-coverts; *olivascens* is smallest race, has entire dorsal surface decidedly greyer and less olive than all others, often a light grey hindcollar (continuation of grey from breast), little or no rufous or cinnamon in wings and tail. Voice. All races emit a distinctive plaintive whistle, "wheeeeu", fading at end. Male gives territorial dawn song, a varied repetition of short, often plaintive phrases, e.g. "wheeu reehr-peu". Also a rising and falling buzzy trill; a sharpish "ki-dee ew" repeated 2-3 times; a gravelly chatter, during interactions; a thin "pheeee" or "seeeee"; and others. Some geographical variation reported in frequency and song pattern; further study required in order to establish possible taxonomic implications.
Habitat. Usually in dry, moist or humid forest (tropical lowland forest, montane evergreen forest), forest borders, canopy at clearings and openings in tall forest, coffee plantations, *várzea*, *igapó*, riparian woodland. In Amazonia, in *várzea* and regrowth forest but not in *terra firme* primary rainforest; in Peru, absent from earliest successional vegetation dominated by *Tessaria* and *Gynerium* along white-water rivers, but at low density in all later stages up to mature forest; also, humid cloudforest and mossy elfin forest 3400 m (*atriceps*). Oak (*Quercus*) and pine (*Pinus*) woodland in USA, and tropical semi-deciduous humid oak-pine cloudforest and dry pine-oak forest in Mexico. From sea-level to above 3000 m; in USA (Huachuca Mts, in Arizona) most abundant below 1800 m but breeds to 2500 m; in Venezuela, to 2000 m N of R Orinoco and to 1300 m S of it; in Andes, to 2400 m (*nigriceps*) and locally as high as 3400 m (*atriceps*).
Food and Feeding. Arthropods, including grasshoppers (Orthoptera), termites (Isoptera), flies (Diptera), damselflies (Zygoptera), mayflies (Ephemeroptera), butterflies and moths (Lepidoptera), beetles (Coleoptera), miscellaneous bugs (e.g. cicadids, membracids), bees and wasps (Hymenoptera), and spiders (Araneae); also berries, and seeds of *Casdaria sylvestris* (in Central America). Forages singly or in pairs; recorded at army-ant swarms. Regularly joins mixed-species flocks throughout range. Forages in dense shrubs and mid-canopy of forest, perching vertically or horizontally and peering about with bowed head, sallying outward or downward to glean insects, often by hover-gleaning.
Breeding. Season mid-May to late Jul in USA; laying mid-Apr to mid-Jun in Mexico, Central America and Trinidad; in South America, breeds Mar-Jun in W & N (*pallidus*, *brunneiceps*, *nigriceps*). Aug-Oct in Amazonia but recorded Apr-May in SE Venezuela (nominate), probably Mar-Jun in W Ecuador; gonads enlarged, eggs in oviduct Sept-Dec in SE Peru and N Bolivia, and recorded mid-Nov to Dec in Andes of Argentina and S Bolivia (*atriceps*). Nest in cavity, material and lining dried weed stems and moss, fine plant fibres, hair, fur, snakeskin, once recorded as taking pieces of eggshell and silver paper almost from feet of campers (presumably for use as nest material); cavities used include those in trees (up to 12 m above ground), deserted woodpecker (Picidae) holes (5 m up), in darkened recesses of dead palm fronds (10 m up), also holes in fence posts, hollow bamboo stems, and in broken top of leaning tree trunk, lowest recorded nest height 25 cm; reported as using cavity in two consecutive years (Central America, Trinidad); one report of possible renesting after loss of first clutch (Arizona). Clutch 3-4 eggs; both parents attend nest; fledging period at least 13 days; no other information.
Movements. Mainly resident. Some local (perhaps primarily altitudinal) movements in N (race *olivascens*); spring migrants found at 1200 m in Arizona (USA), and recorded in pine-oak woodland to 2100 m and riparian woodland down to 1000 m in N Sonora (Mexico). Cozumel I population (*platyrhynchus*) absent in winter; winter range unknown but a migrant found near coast of E Honduras. Evidence of movements, possibly altitudinal, or mid-distance migration, in Bolivia: *atriceps* reportedly only a breeding visitor in S Bolivian Andes, present throughout year to N.
Status and Conservation. Not globally threatened. Uncommon to abundant. In many regions the most common and widespread *Myiarchus* flycatcher. Estimated global population 20,000,000 individuals. Apparently slight recent extension of range N in USA, but survey data showed no constant trend. Given its tolerance of somewhat disturbed habitats, its general abundance and its very large range, this species is unlikely to become threatened. Occurs in numerous national parks and other protected areas throughout its distributional area.

378. Swainson's Flycatcher

Myiarchus swainsoni

French: Tyran de Swainson **German**: Swainsonschopftyrann **Spanish**: Copetón de Swainson
Other common names: Pelzeln's Flycatcher (*pelzelni*); Whiteley's Flycatcher (*phaeonotus*)

Taxonomy. *M[yiarchus] Swainsoni* Cabanis and Heine, 1859, Rio de Janeiro, Brazil.
A taxonomically difficult complex; in need of revision that carefully integrates molecular and morphological data. Nominate race is larger and/or darker than most others, also differs vocally, and phylogenetic analysis of mitochondrial DNA indicates that it is not closely related to other races; almost certainly represents a separate species. From mtDNA studies, other races appear extraordinarily closely related to each other (although *phaeonotus* not included in samples), and also closer to *M. tuberculifer* and *M. barbirostris* than to all other taxa in genus (as mirrored in voice-playback experiments). Hypothesis that variation between races *pelzelni* and *ferocior* (possibly including *phaeonotus*) is clinal, with increase in size and increasingly paler upperparts from N to S, needs to be tested. Phenotypic intergradation occurs between nominate and *ferocior*, but at mtDNA level this is unidirectional, and hitherto only mtDNA from latter taxon recorded in zone of morphological intergradation. Field and laboratory studies needed. Birds from N sandy savanna of Surinam described as a further race, *albimarginatus*, but characters appear attributable to fresh-plumaged intergrades between *phaeonotus* and *pelzelni*. Notably, two such intergrade specimens from nearby Guyanan savannas have highly divergent mtDNA; further study required. Four subspecies currently recognized.
Subspecies and Distribution.
M. s. phaeonotus Salvin & Godman, 1883 - tropical and subtropical zones of SE Venezuela, W Guyana and adjacent N Brazil (upper R Negro and R Branco).
M. s. pelzelni Berlepsch, 1883 - S & E perimeter of Amazon Basin S to SE Peru, N Bolivia and SC Brazil (S to Mato Grosso, S Goiás and Minas Gerais).
M. s. swainsoni Cabanis & Heine, 1859 - breeds SE Paraguay and SE Brazil (São Paulo, Rio de Janeiro) S to extreme NE Argentina (Misiones) and Uruguay; migrates to N South America, from E Colombia, W Venezuela and Trinidad E to NE Brazil (Paraíba).
M. s. ferocior Cabanis, 1883 - breeds SE Bolivia, W Paraguay and Argentina (S to La Pampa and Buenos Aires); migrates to Amazon Basin as far N as S Colombia.
Descriptive notes. 19·5-21 cm; male 21·5-28·5 g, female 21·3-28·9 g (*swainsoni*), male 34·6-37·6 g (*ferocior*), both sexes 19·8-26 g (Surinam), means for both sexes 21-25·38 g (various races). Larger, dark-tailed *Myiarchus*. Nominate race has crown and upperparts a nondescript dull olive grey-green with no marked contrast, except tending to slightly browner colour on uppertail-coverts; lores and face usually not noticeably lighter than crown; wings brown, primaries with rufous outer edges and secondaries and tertials with pale whitish-yellow outermost webs (in fresh plumage), innermost webs of tertials dirty whitish to rufous, contrasting with brown of rest of feathers;

greater and median wing-coverts broadly tipped fuscous grey or, only occasionally, clear white (two indistinct wingbars); tail plain brown, outermost webs of outermost rectrices sometimes slightly paler, in fresh plumage often some rectrices with rufous fringe; throat and breast grey, usually tending to be paler on throat, abdomen and undertail-coverts yellow with somewhat grey tinge, upper flanks often with distinctly green wash, tibial feathering olive-brown; underwing-coverts yellow; iris dark; upper mandible brown, lower mandible pale rufous-brown to pinkish; legs blackish. Sexes similar. Juvenile has rufous tips of wing-coverts and fringes on tail (although specimens with fully ossified skull can have rufous wing-covert tips). Race *phaeonotus* is dark smoky grey, almost blackish, above, bill all black; *pelzelni* has no dark suffusion in olive-green upperparts, slightly paler throat and underparts than nominate; *ferocior* is palest, dorsal colour plain but light olive-green, brownish-olive auriculars darker than rest of head, yellower (less grey) below. Voice. Mournful whistle commonly heard; dawn song comprises alternated mournful whistles, "huit" notes and more complex phrases; repeated rolls and rasps in response to intruding conspecifics.

Habitat. Variety of habitats, but primarily clearings, wooded areas (especially *cerrado*, savannas), light scrub, riparian vegetation. Wooded slopes of tepuis and clearings in tropical forest, to 1800 m (*phaeonotus*); canopy of subtropical hill forest, also to 1200 m in more lightly wooded drier valleys (*pelzelni*). Nominate race recorded in 60-ha fragment of vegetation (isolated by 2 km from any other large forest area), with *Aspidosperma polyneuron*, *Euterpe edulis*, *Galesia inetgrifolia* and *Ficus glabra* as dominant trees; also in fragments (7·6-47·3 ha) in an urban environment. In non-breeding season, race *ferocior* recorded in Chaco and rainforest, in Peru not in earliest successional vegetation dominated by *Tessaria* and *Gynerium* along white-water river but present in later stages up to mature forest; to 2600 m in Colombia (near Bogotá). Nominate race also found in mangroves on non-breeding grounds in Venezuela and Surinam.

Food and Feeding. Insects, also fruits; insects and seeds of berries in stomach contents (nominate race). Reported as "quite frugivorous" in non-breeding areas. Nestlings fed with insects, e.g. dragonfly (Odonata), and berries. Recorded as feeding on insects 30 cm above ground in bushes; nominate race has been observed in all strata of "scrub" in varying stages of succession, but most often in mid-strata. Of 61 observations of non-breeding *ferocior* in Peru, most were of birds using outward hover-gleaning to capture prey, with minor proportions of aerial hawking and striking, and some observations of frugivory.

Breeding. Feb-May in N (*phaeonotus*), Sept-Dec in Amazon Basin (*pelzelni*) and Nov to early Jan in S (nominate and *ferocior*). Nest materials dried stems and moss, fine plant fibres, similar to those used by congeners; nest usually in tree cavity, sometimes under house roof, also in nestbox; nests in boxes used by nominate race had much plant material (principally "paina") and some pieces of snakeskin and feathers in upper layers, but animal material generally not common in upper layer; in Argentina, one nest with external diameter 8 cm, internal diameter 6 cm and depth 4 cm, placed 4 m above ground in old nest of Rufous Hornero (*Furnarius rufus*), another had external diameter 10 cm, height 5 cm, internal diameter 5 cm, depth 3 cm, located 4·2 m up in hollow of decayed branch of *Prosopis*; nestboxes used twice consecutively in Brazil (São Paulo). Clutch 3 or 4 eggs (*M. s. swainsoni*); no information on incubation and fledging periods.

Movements. S populations of nominate and *ferocior* migratory, moving to, respectively, N South America (E Colombia E to E Brazil) and Amazon Basin (N to S Colombia); migratory status of more N breeding populations of these races, however, unclear. Nominate tracks relatively constant temperature range throughout year during course of annual migration. Migratory status of *pelzelni*, and that of intergrading races, warrants further study.

Status and Conservation. Not globally threatened. Fairly common to common. Occurs in at least twelve national parks and many other protected areas throughout its very large range. Able to live a reasonably wide range of wooded habitats, and thought unlikely to be at any risk in the near future.

Bibliography. 379. Venezuelan Flycatcher

Myiarchus venezuelensis

French: Tyran du Venezuela **German**: Venezuelaschopftyrann **Spanish**: Copetón Venezolano
Other common names: Fierce Flycatcher

Taxonomy. *Myiarchus venezuelensis* Lawrence, 1865, Lago de Valencia, Carabobo, Venezuela.

Formerly treated as a race of *M. ferox*. Analyses of morphological characters and mitochondrial DNA indicate close affinities with that species and also with *M. phaeocephalus* and *M. panamensis*, but precise relationships within that group unclear. In study of phylogeny of genus, mtDNA of a single individual of present species examined was nested within *M. ferox*, suggesting past hybridization between the two, or incomplete sorting of mtDNA in this group of species, or misidentification (as no voucher was available). Careful ecological and genetic study of these species in zones of parapatry and sympatry should be rewarding. Tobago birds appear darker dorsally, but difference slight and constancy of this character untested; subspecific separation as *insulicola* unwarranted at present. Monotypic.

Distribution. Apparently three, possibly four, disjunct populations. Caribbean lowlands of Colombia (N Sucre E to Guajira), and E of Andes in Norte de Santander (Cucutá); NW & N Venezuela (Zulia; and far E Falcón and E Yaracuy E through lowland Carabobo and Aragua to Distrito Federal, E to Puerto La Cruz); and recorded also NE & E Venezuela (Margarita I; NE Bolívar) and Tobago. Records from Zulia (Cerro Alto del Cedro, La Esperanza) may be referable to Colombian population (to W) or to Venezuelan ones (to E), or may represent a separate population.

Descriptive notes. 19 cm; male 27-32 g, female 27-33 g, unsexed 26-28 g. Generally unremarkable *Myiarchus* with combination of reasonably apparent whitish streaking on grey breast and very pallid yellow belly. Plumage is dark olive-green above, centres of crown feathers darker and creating both streaked effect and a contrast with upperparts; sometimes crown and back darker and contrasting slightly with greyer mantle and uppertail-coverts (Tobago); primaries often edged strongly with rufous, outer webs of tertials pale whitish-yellow, two well-marked wingbars (in fresh plumage); tail brown, outer webs of outer pair of rectrices noticeably paler than inner ones, outer webs of other rectrices conspicuously fringed with brown or cinnamon-yellow, normally no rufous (likely only in fresh plumage); throat and breast grey, whitish feather centres on especially throat and upper middle breast creating distinctive streaked appearance; belly and undertail-coverts washed-out pallid yellow; tibial feathering olive-brown; iris, bill and legs dark. Differs from similar *M. panamensis* in being paler below, usually more rufous in primaries; from lighter-backed forms of *M. ferox* in streaked breast and very pallid yellow belly. Sexes similar. Juvenile presumably has rufous-tipped wing-coverts and more pronounced rufous on tail. Voice. Repeated hiccups, rasps, rasp-whistles and "wheer-r-r" notes in response to intrusion by conspecifics ("wheer-r-r" similar to that of *M. tuberculifer*, the only other species for which this vocalization recorded). Plaintive whistles during foraging. Dawn song comprises identical whistles but in series with 4, 8 or 10 seconds between each. Vocal repertoire differs from that of *M. ferox* and *M. panamensis*, has no rolls or "huit" notes.

Habitat. Clearings and borders of dry and moist forest and deciduous (in understorey) and semi-deciduous woodland; drier scrubby pasture with scattered trees and brushy borders. Recorded in cocoa plantations in Venezuela (Aragua). Found in clearings in higher forested areas, but not in coastal lowlands, on Tobago. To 600 m.

Food and Feeding. Insects and small fruits. Forages in middle storey of trees or tall shrubs, perching vertically or horizontally and peering about with bowed head, sallying outward or downward to glean insects, often by hover-gleaning.

Breeding. Season late Mar to early Jun; males with testes unenlarged in Jan, enlarged in May; females with brood patches and eggs in oviduct in May; also, laying reported in Oct. No other information.

Movements. Resident.

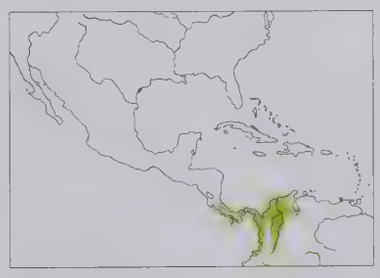
Status and Conservation. Not globally threatened. Generally considered uncommon to fairly common, but is often overlooked. Occurs in Henri Pittier National Park, in Venezuela. Poorly known species.

Bibliography. Carriker (1954), Chapman (1917c), Cory & Hellmayr (1927), ffrench (1991), ffrench & Kenefick (2003), Haffer (1975), Haffer & Borrero (1965), Hilty (2003), Hilty & Brown (1986), Joseph *et al.* (2004), Lanyon (1978), Ridgely & Tudor (1994), Ridgway (1907), Sharpe *et al.* (2001), Snow (1985a), Stotz *et al.* (1996), Verea & Solórzano (1998, 2001), Verea *et al.* (2000), Visbal *et al.* (1996), Wetmore (1939).

380. Panama Flycatcher

Myiarchus panamensis

French: Tyran du Panama **German**: Panamaschopftyrann **Spanish**: Copetón Panameño



Taxonomy. *Myiarchus panamensis* Lawrence, 1860, Atlantic slope of Canal Zone on Panama Railroad, Isthmus of Panama.

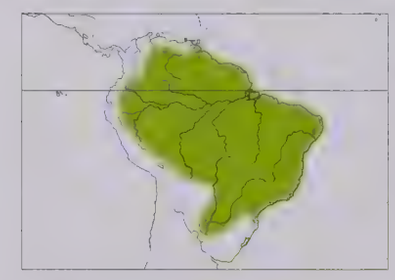
Formerly treated as a race of *M. ferox*, but the two differ in vocalizations and do not respond to playback of voice of each other; similarly, species-level separation from *M. venezuelensis* argued on basis of sympatry in extreme NW Venezuela (near Cerro Alto del Cedro) and in N Colombia (Cansoma, in Bolívar). Analyses of morphological characters and mitochondrial DNA indicate close affinities with those two species and also with *M. phaeocephalus*, but precise relationships within that group unclear. Careful ecological and genetic study in zones of parapatry and sympatry would be rewarding. Re-examination of geographical distributions of these taxa and their ecology and taxonomy, especially S & E of L Maracaibo (W Venezuela), is warranted. Two subspecies recognized.

Subspecies and Distribution.

M. p. actiosus Ridgway, 1906 - Pacific coast of Costa Rica (Gulf of Nicoya S to point N of Osa Peninsula).

M. p. panamensis Lawrence, 1860 - extreme SW Costa Rica (Rincón de Osa, Puerto Jiménez), Panama (Caribbean slope in W Bocas del Toro and from N Coclé E to San Blas, lowlands and foothills on Pacific coast, also Pearl Is, Coiba I, Taboga I and other smaller islands), N & W Colombia (E to Guajira Peninsula, S to Tumaco, in SW Nariño, lower Cauca Valley and upper Magdalena Valley at least to Neiva and Villavieja) and Maracaibo region of NW Venezuela.

Descriptive notes. 19 cm; 28·1-38·5 g. Relatively plain olive-backed *Myiarchus* with no rufous in tail, faint wingbars. Nominate race is greyish-olive above, centres of crown feathers darker and creating both streaked effect and a contrast with upperparts; wings as back, outer webs of tertials pale whitish-yellow; tail brown, outer pair of rectrices usually with outer vanes barely paler than inner ones, normally no rufous (likely only in fresh plumage); throat and breast grey, breast and undertail-coverts yellow, tending to be brighter in centre of abdomen, upper flanks often with greenish wash, tibial feathering olive-brown; iris, bill and legs dark, lower mandible sometimes slightly paler basally (upper Magdalena Valley, in Colombia); inside of mouth orange. Distinguished from similar *M. venezuelensis* by darker and unstreaked throat, less rufous in primaries, brighter and more lemon-yellow belly; from extremely similar *M. ferox* by generally lighter dorsal surface, but often indistinguishable on basis of plumage alone. Sexes similar. Juvenile has wing-coverts and tail feathers edged rufous. Race *actiosus* has greyer upperparts and paler abdomen than nominate. Voice. Repeated hiccups (normally disyllabic), rasping whistles and rolls in response to intruding conspecifics; long series of rasping whistle notes followed by one or more roll notes that descend in frequency; occasional "huit" note given. Dawn song comprises isolated, short, slowly modulated whistles given every 2-3 seconds (identical with



less frequently emitted notes given by foraging birds at other times of day). Differences in calls from those of *M. ferox* exceed usual degree of difference between *Myiarchus* species.
Habitat. Tropical deciduous forest, gallery forest, secondary forest, mangrove forest and arid lowland scrub; open woodland, also other semi-open habitats (borders of fields, pastures with scattered brush). Mangroves especially W of Andes; race *actiosus* confined to mangroves. Sea-level to 1400 m.
Food and Feeding. Insects and fruit; grass "berries" in edge habitat. Hawks flying insects from open perches; sallies to snatch prey from vegetation. Runs along ground or mangrove roots in manner of a thrush (*Turdus*), sallying up at flying or resting insects.
Breeding. Breeds late Mar to early Jun; possibly later, May-July, in upper Magdalena Valley (Colombia), as suggested by pre-breeding moult being completed late Apr and juveniles found as late as mid-Oct. Nest in cavity, lined with bulky mass of rootlets, vines, leaf fragments, plant down, animal hair and snakeskin, usually 4-12 m above ground in tree, occasionally under an eave; also recorded as using nestboxes, upper end of metal pipe (diameter 10 cm) set at an angle in ground, and crevice 3 m above ground in low cliff flanking road. Clutch 2-3 eggs; no information on incubation and fledging periods.
Movements. Presumably sedentary; possibly minor altitudinal movement in Colombia.
Status and Conservation. Not globally threatened. Uncommon to fairly common; uncommon in E Panama (Darién). Occurs in Carara Biological Reserve and Tarcol Lodge, in Costa Rica, and Tambito Nature Reserve, in Colombia.
Bibliography. Anon. (1998a), Burton (1973), Chapman (1917c), Cory & Hellmayr (1927), Haffer (1975), Haffer & Borrero (1965), Hellmayr & Seilern (1915), Hilty (2003), Hilty & Brown (1986), Joseph *et al.* (2004), Lanyon (1978), Nelson (1904), Olson (1997), Ralph & Chaplin (1973), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1946, 1952, 1957, 1972), Wright *et al.* (1985).

381. Short-crested Flycatcher

Myiarchus ferox

French: Tyran féroce **German**: Kurzschopftyrann **Spanish**: Copetón Feroz

Taxonomy. [*Muscicapa*] *ferox* J. F. Gmelin, 1789, Cayenne.
Formerly included *M. venezuelensis* and *M. panamensis* as races. Analyses of morphological characters and mitochondrial DNA indicate close affinities with those species and also with *M. phaeocephalus*, but precise relationships within that group unclear. In study of phylogeny of genus, mtDNA of single individual of *M. venezuelensis* examined was nested within present species, suggesting past hybridization between the two, or incomplete sorting of mtDNA in this group of species, or misidentification of that single sample (as no voucher was available). Careful ecological and genetic study of these species in zones of parapatry and sympatry should be rewarding. Geographical variation in present species complex and incompletely understood. Plumage differentiation among the three races is slight, and vast zones of intergradation are currently recognized. Populations in hybrid zone between nominate and *brunnescens* were thought by some earlier authors to be migrant *australis*, but this is refuted by their having different breeding and moult schedules (many intermediate birds, however, distinguishable from *australis* only through these differences in timing). Molecular phylogeographical analysis of 14 samples from this intergradation zone and from the core Amazonian range of nominate revealed no phylogeographical structure; notably, samples from these two regions and from a third, C Guyana (Iwokrama), each fell in a different clade; given that no samples from core ranges of either *brunnescens* or *australis* were included, however, these results may reflect mtDNA of nominate race only. Further study needed in order to clarify phylogeography and evolutionary history of this species. Three subspecies currently recognized.
Subspecies and Distribution.
M. f. brunnescens J. T. Zimmer & Phelps, Sr, 1946 - core range a narrow belt of *llanos* in SW Venezuela (Táchira and Portuguesa E to NW Bolívar) and extreme NE Colombia.
M. f. ferox (J. F. Gmelin, 1789) - Amazon Basin (from E slopes of Andes in S Colombia, Ecuador, Peru and N Bolivia) E to E & S Venezuela, the Guianas and Brazil.
M. f. australis Hellmayr, 1927 - lowlands from SE Bolivia, C Brazil (through S Mato Grosso, S Goiás, S Minas Gerais) and S through drainages of R Paraguay, R Paraná and R Uruguay to Argentina (S to S Corrientes) and extreme SW Rio Grande do Sul (Brazil); possibly also N & W Uruguay.

Descriptive notes. 18 cm; male 21-33 g, female 23·5-34 g. A generally larger, dark-tailed, slightly crested *Myiarchus*, noticeably sooty-grey to darkish olive-green above. Nominate race is typically smoky brown above, little or no contrast between crown and upperparts; wings relatively plain dark brown, greater and median wing-coverts broadly tipped with paler fuscous-brown (tending paler on medians), outermost webs of tertials whitish-yellow to greyish (probably proportional to amount of wear); rectrices dark smoky brown, fringed with rufous only in fresh plumage; throat and breast grey (tending lighter on upper throat), grey extending onto lores and face, the latter darker grey than lores; abdomen and undertail-coverts yellow, tibial feathering olive-brown, underwing-coverts yellow; iris, bill and legs dark. Sexes similar. Juvenile has rufous tips on wing-coverts, rufous edges on innermost and outermost webs of tertials and outermost webs of rectrices. Races vary mainly in plumage tone, but complicated by extensive intergradation: *brunnescens* is lighter brown above than nominate, has more rufous fringing on rectrices (fresh plumage), upper flanks washed with olive-green; *australis* similar to previous, with crissum less brown. Voice. Short, slowly vibrato-modulated whistles given infrequently during foraging; vocal response to intruding conspecifics comprises rasping whistles, hiccups, and sometimes strident rattles; a rattle call given in response to playback, unique in genus. Dawn song comprises isolated whistles with vibrato modulation, identical to sounds made while foraging during day.
Habitat. Clearings in forested areas, woodland borders, *cerrado*, *várzea*, *igapó*, riparian woodland and agricultural areas. In primary successional gradient associated with a white-water river in Peru, inhabited monocultures of the woody composite *Tessaria* and also *Tessaria* invaded by the cane *Gynerium sagittatum*. Tropical zone mostly below 500 m but up to 1000 m; record at 1375 m in Peru (Cuzco), possibly a response to forest clearance.
Food and Feeding. Insects and fruits; recorded food items in Surinam beetles (Coleoptera), hemipterans, including heteropteran stink or assassin bugs (Reduviidae), and *Capsicum* berries. Analysis of 38 prey items taken from stomachs in SE Peru gave: Hymenoptera (ants 21%, bees and wasps 16%); Hemiptera (Pentatomidae 24%, other 6%); Homoptera (cicadas 13%, planthoppers 3%); Diptera (11%); Orthoptera (3%); and Coleoptera (3%). Forages singly or in pairs, scanning from perches in middle and lower levels; average perch height recorded as 4·7 m in forest edge and 2·1 m in savanna. In Amazonian savanna, forages mostly by upward-striking in vegetation; along Peruvian river-edges, forages with upward strikes and outward hover-gleans 1-4 m above ground within and at edges of shrubby growth.
Breeding. Nominate race and *australis* breed mainly Jul-Dec; nests with eggs in Surinam populations currently ascribed to nominate found Oct-Dec (one exceptional report of eggs in mid-Apr), nine specimens of nominate from N Brazil (Amapá, Belém) in Jul and Sept-Nov have enlarged gonads, three Dec birds from Guyana have gonads enlarged (one female, one male) or, possibly, regressing (one female); *brunnescens* and populations currently considered intermediate between it and nominate (all or most of which are N of equator) breed Mar-May, thus when S populations of nominate and *australis* are in fresh plumage or completing annual moult. Nest typical of genus, in tree cavity and lined with feathers, fur and shed skin of snakes and lizards, lining also recorded as including plant material ("paina") from two species of Asclepiadaceae, grasses, palm fruits and various unidentified leaves and roots; layers of lining suggest that nests reused; recorded nests in natural sites have been low, one (in Surinam) was in a low *Curatella americana*, others (in Mato Grosso, in Brazil) were 1 m and 1·3 m above ground in angled tree trunk over water. Clutch 2 eggs (Surinam) or 3 eggs (Mato Grosso, Brazil); no information on incubation and fledging periods. Nests probably parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Sedentary.
Status and Conservation. Not globally threatened. Fairly common to common. Estimated population density in primary successional habitat in Peru 56·5 birds/100 ha (both in monocultures of *Tessaria* and in *Tessaria* invaded by *Gynerium sagittatum*). Thrives in secondary and more open habitats; possibly increasing and expanding range as a result of deforestation. Occurs in many national parks and other protected areas throughout its large range.
Bibliography. 382. Apical Flycatcher

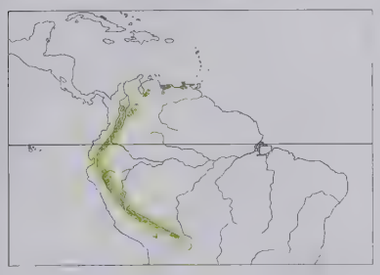
Myiarchus apicalis

French: Tyran à queue givrée **German**: Kolumbienschopftyrann **Spanish**: Copetón Apical

Taxonomy. *Myiarchus apicalis* P. L. Sclater and Salvin, 1881, "Bogotá" = Honda, Tolima, Colombia.
Affinities uncertain, as present species not included in recent phylogenetic analysis of genus; it is predicted that it is probably either sister to *M. ferox* and *M. phaeocephalus* or paraphyletic with them. Monotypic.
Distribution. Upper parts of four river systems in WC Colombia: Cauca Valley (Valle and Cauca, one record from Antioquia), Pacific slope in arid valleys of upper R Dagua (Valle), upper R Patía (Nariño and valley of R Calima), and Magdalena Valley (Santander and Boyacá S to Huila).



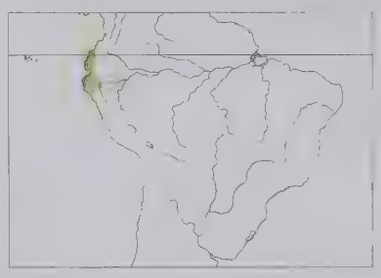
Descriptive notes. 17 cm; 26-33·5 g. The only *Myiarchus* with conspicuous pale whitish tail tips; crest more bushy than on most congeners. Crown is brownish-olive, darker feather centres creating streaked appearance, and contrasting slightly, if at all, with darkish olive upperparts; wings brownish, pale whitish to yellowish tips and outer edges of greater and median wing-coverts and outer edges of secondaries and tertials, faint yellowish outer edges of innermost primaries; tail brownish, pale creamy tips on all except central rectrices (at least 8 mm on outermost feathers), some rectrices sometimes fringed with olive-green; throat and breast grey, whiter on throat, breast side washed olive, rest of underparts yellowish, tibial feathering olive-brown; underwing-coverts yellow; iris, bill and legs dark. Sexes similar. Juvenile presumably has rufous edges on wing-coverts and rectrices. Voice. Repeated rolls, hiccups and whistles in response to intruding conspecifics; typically, gives long series of rolls without interjection of other vocalizations. Dawn song unknown.
Habitat. Most numerous in scrubby vegetation of dry to arid valleys; also recorded in forest and lighter woodland borders, riparian trees and brush. A farm study site embedded in a suburban area where a nesting pair was studied for several years was mainly pasture, with rice and sorghum fields, a few large trees (*Ceiba pentandra*, *Samanea saman*, *Erythrina glauca*), and some small shade trees 5-8 m tall (*Guazuma ulmifolia*, *Pithecellobium dulce*, *Fagara rhoifolia*). From 400 m to 2000-2500 m, primarily below 1700 m.
Food and Feeding. Insects and small fruit; a beetle (Coleoptera) found in one stomach. Singly or in pairs. Forages by sallying from perch at middle and lower levels.
Breeding. Laying recorded in Jul, Sept and Nov-Feb; males with enlarged testes late Jan to mid-Apr. Nests found in tree cavity 5 m up and in isolated stump in pasture, also in nestboxes. Following details refer to a pair studied Sept 1990 to Feb 1997 in a suburban area, where seven nesting attempts made (last of which in Jan 1995), all in nestboxes within area of 4 ha. Nest a base of sticks 5 cm deep, with layer of dry grass and fur on top and forming cup 7 cm across, lined with fur, feathers, snakeskin and pieces of plastic; mean clutch size 2·6 eggs; hatching asynchronous, 24 hours apart; nestling period 16-17 days. Female laid total of 18 eggs in seven clutches; four clutches fledged total of 11 young; two were preyed on, and outcome of the other was unknown. Female (ringed) remained in same pasture (26 km S of Cali, in Valle) for 6·5 years.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Colombian Inter-Andean Valleys EBA. Uncommon to locally fairly common. Common in upper Dagua Valley W of Cali (in Valle). Possibly expanding locally as secondary woodland, scrub and pasture replace cleared humid forest above 1700 m. Despite its relatively small range, it is therefore not threatened, but is not known to occur in any protected areas.
Bibliography. Anon. (2003g), Chapman (1917c), Cory & Hellmayr (1927), Hilty & Brown (1986), Kattan *et al.* (2000), Lanyon (1978), Meyer de Schauensee (1982), Miller (1947), Ridgely & Tudor (1994), Stotz *et al.* (1996).

383. Pale-edged Flycatcher

Myiarchus cephalotes

French: Tyran givré **German**: Andenschopftyrann **Spanish**: Copetón Montañero

Taxonomy. *Myiarchus cephalotes* Taczanowski, 1880, Tambillo, northern Peru.
Precise relationships within genus unclear from analysis of mitochondrial DNA; present species possibly sister to *M. ferox* and *M. phaeocephalus* (perhaps also with *M. apicalis*). Two subspecies recognized.
Subspecies and Distribution.
M. c. caribbaeus Hellmayr, 1925 - N & W Venezuela (N coastal range in Aragua and Distrito Federal, mountains of Sucre and N Monagas, Andes of Lara and Trujillo).
M. c. cephalotes Taczanowski, 1880 - Colombia (C range of Andes), Peru (slopes of E and C cordilleras) and Bolivia (Yungas).



Descriptive notes. 18-19 cm; male 22·5-31 g, female 20·5-28 g (*cephalotes*), male 22·5-27·5 g, female 23-24·5 g (*caribbaeus*). The only *Myiarchus* with pale yellowish outer webs of outermost rectrices (often visible when viewed from below). Has crown brownish-olive, with slightly darker feather centres creating weakly streaked appearance, lores pale grey, upperparts olive-green; wings brownish-olive, yellowish tips and outer edges of greater and median wing-coverts, yellowish outer edges of secondaries and tertials (slightly more whitish on tertials); tail brownish-olive, with outer webs of outermost rectrices typically whitish and noticeably paler than the inner webs; throat and breast grey, slightly paler on throat; abdomen and undertail-coverts yellow, tending to be more richly coloured in middle of abdomen, tibial feathering olive-brown; underwing-coverts yellow; iris, bill and legs dark. Sexes similar. Juvenile has edgings of wing-coverts at least tinged with rufous, rufous margins on all but outermost rectrices, and tending to have rufous-brown tips on some feathers of upperparts. Race *caribbaeus* is smaller than nominate, and outer webs of outermost rectrices on average paler. Voice. Dawn song a series of piercing whistles given at intervals of at least 5 seconds; daytime contact call a similar whistle.
Habitat. Inhabits borders of moist and humid forests, clearings in forest, and open woodland. Occurs in subtropical and lower temperate zones, at 800-3000 m; 1400-2200 m in Venezuela (race *caribbaeus*).
Food and Feeding. Insects, including beetles (Coleoptera), wasps (Hymenoptera) and caterpillars; also berry seeds ("pits"). Sallies to hover-glean from foliage and branches; occasionally sallies in air.
Breeding. Breeds Apr-Jun in Venezuela and Colombia; males with enlarged testes and females with oviduct slightly enlarged and ova up to 2 mm in early May. In Colombia (near Popayán), an individual gathering plant fibres, presumably as nest material, and the same or another individual later seen to peer into nearby natural tree cavity. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Uncommon to locally common. Fairly common in Serranías Cofán (Sucumbíos), in Ecuador, and along Maracay-Choroní pass, in Venezuela; occurs in Macarao National Park, in Venezuela, Tambito Nature Reserve and Cueva de los Guácharos National Park, in Colombia, Machu Picchu Historical Sanctuary, in Peru, and Madidi National Park, in Bolivia. Given its flexibility in habitat choice and its relatively large range, this species is not at any risk.
Bibliography. Chapman (1917c, 1921), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hellmayr (1925), Hennessey, Herzog & Sagot (2003), Hilty (2003), Hilty & Brown (1986), Joseph *et al.* (2004), Lanyon (1978), Meyer de Schauensee (1982), Perry *et al.* (1997), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Traylor (1958), Walker (2001), Zimmer (1930, 1938).

384. Sooty-crowned Flycatcher

Myiarchus phaeocephalus

French: Tyran à front gris **German**: Rußkappen-Schopftyrann **Spanish**: Copetón Tiznado

Taxonomy. *Myiarchus phaeocephalus* P. L. Sclater, 1860, Babahoyo, Ecuador.
Phylogenetic analysis of mitochondrial DNA found one phenotypically typical individual of race *interior* more closely related to clade formed by *M. venezuelensis*, *M. panamensis* and *M. ferox* than to two nominate individuals of present species. Further study of decoupled molecular and morphological evolution needed. Races weakly differentiated. Two subspecies recognized.
Subspecies and Distribution.
M. p. phaeocephalus P. L. Sclater, 1860 - W Ecuador (S from N W Esmeraldas and W Pichincha) and NW Peru (S to Lambayeque).
M. p. interior J. T. Zimmer, 1938 - extreme SE Ecuador (near Zumba, in S Zamora-Chinchipe) and N Peru (upper R Marañón drainage in Cajamarca and Amazonas).

Descriptive notes. 18-19 cm; 24-29·5 g. The only *Myiarchus* with combination of blue-grey crown, greyish nuchal collar and olive-green back. Forehead and forecrown are light blue-grey, becoming darker grey on hindcrown and nape, dark centres of feathers creating streaked appearance (more pronounced on forecrown); lores and face slightly paler grey than crown; crown contrasts with lighter olive-green upperparts, often a light grey collar several millimetres wide between darker crown and lighter back; wings brownish-olive, tips of greater and median wing-coverts slightly paler, margins of tertials pale yellowish; tail brownish-olive, outer webs of outer rectrices paler, tending to yellowish-olive; throat and chest grey, marginally lighter on throat; abdomen and undertail-coverts light yellow, tibial feathering olive-brown, underwing-coverts yellow; iris, bill and legs dark; mouth-lining orange. Sexes similar. Juvenile apparently undescribed. Race *interior* differs from nominate only in slightly browner crown and back, slightly richer yellow abdomen, on average slightly shorter wing. Voice. Repeated hiccups, rasping whistles and high-pitched whistles in response to intruding conspecifics, the hiccup normally a disyllabic modification of the "huit" note given by many congeners; whistle notes during foraging. Dawn song a series of whistles as those when foraging during daylight, but given at more constant rate; initial whistle has piercing quality, remaining whistles more plaintive, declining in frequency and amplitude.
Habitat. Deciduous woodland, arid scrub, sometimes edge of mangroves in lowlands and foothills; tropical zone to c. 1500 m.
Food and Feeding. Insects. Sallies from tree perches.
Breeding. Breeds Feb-Apr; copulation observed Jan-Mar. Nest in cavity lined with fur, snakeskin and clear plastic, typical of genus. Mean clutch size 4 eggs. No other information.
Movements. Presumably sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA and Marañón Valley EBA. Uncommon to fairly common. Common in Chongon Hills, and also occurs in Machalilla National Park, Cerro Blanco Forest Reserve and Loma Alta Ecological Reserve, all in Ecuador; occurs in Northwest Peru Biosphere Reserve, in Peru. Forest habitats within Tumbesian region are being rapidly destroyed, degraded and fragmented. In W Ecuador below 900 m, deforestation rates of 57% per decade from 1958 to 1988; at higher elevations, deforestation has been slower, but still less than 5% of original forest cover remains, mostly on inaccessible slopes. Even protected areas are subjected to logging, livestock grazing, illegal settling and habitat clearance by people with land rights. Marañón drainage has also lost most of its original forest cover as a result of logging and agriculture, and no protected areas exist. This species' ability to live in scrub habitat should aid its future survival.
Bibliography. Best *et al.* (1996), Cory & Hellmayr (1927), Joseph *et al.* (2004), Lanyon (1978), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Stotz *et al.* (1996), Wiedenfeld *et al.* (1985), Williams & Tobias (1994), Zimmer (1938).

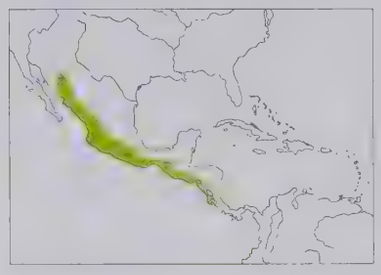
385. Ash-throated Flycatcher

Myiarchus cinerascens

French: Tyran à gorge cendrée **German**: Kalifornien-Schopftyrann **Spanish**: Copetón Cenizo

Taxonomy. *Tyrannula cinerascens* Lawrence, 1851, western Texas.
Phylogenetic analysis of mitochondrial DNA placed this species in a clade with *M. yucatanensis*, *M. crinitus* and *M. tyrannulus*. Was in the past sometimes considered conspecific with *M. nuttingi*, but differs in mouth-lining colour, vocalizations, rectrix pattern, wing formula, and morphometrics; no evidence of hybridization between the two. Race *pertinax* differs slightly from nominate in average measurements, but not diagnosably distinct in plumage or vocal characters; perhaps represents end point of a cline and, as such, of doubtful validity. Two subspecies recognized.
Subspecies and Distribution.
M. c. cinerascens (Lawrence, 1851) - breeds W USA (C Washington, Idaho, Wyoming, W Colorado) S to C Mexico; winters from S USA to Honduras, mainly on Pacific slope.
M. c. pertinax S. F. Baird, 1859 - S Baja California (Mexico).

Descriptive notes. 19-20·5 cm; 24-31 g. Has crown and upperparts drab grey, crown feathers with dark centres (creating subtle streaked appearance); face and auriculars slightly paler than upperparts, lores pale grey, uppertail-coverts variably with rufescent tinge; wings browner, broad rufous outer edges of primaries, greyish-white outer edges of secondaries and tertials; greater and median wing-coverts broadly tipped greyish-white, creating two wingbars; rectrices, except central pair, with broad rufous band on inner webs but not extending to tips, tips and outer webs of rectrices greyish-brown, perhaps with olive tinge on edges; throat and breast ashy grey, grey sometimes extending around upperparts to form narrow grey collar; diffuse whitish band in lower breast/upper abdomen region, abdomen and undertail-coverts pale yellow (tending richer in centre of abdomen); tibial feathering olive-brown; underwing-coverts yellow; bare parts dark; inside of mouth pale ochraceous buff. Sexes similar. Juvenile has wing-coverts, uppertail-coverts, remiges and rectrices edged buff or cinnamon-rufous, underparts paler, tail lacking adult pattern. Race *pertinax* is not constantly different from nominate in plumage but tending paler on abdomen, and with wing shorter (by 3 mm) and more rounded, tail shorter (by 2 mm), bill slightly longer (by 0·3 mm), but overlap extensive. Voice. Sharp "bik" call, also "ki-brrrnk-brr"; short, soft "prrt" in non-breeding season. Song a repeated "kiprr", also short "kabrík". Dawn song repeated "ha-wheer"; dawn song of race *pertinax* reported as different, but not substantiated in more detailed study.
Habitat. Desert scrub (*chaparral*, thorn-scrub), open deciduous woodland and brushy pastureland (especially non-breeding season), coniferous and mixed woodlands (pinyon-juniper and oak), and riparian forest. Sea-level to 2000 m.
Food and Feeding. During breeding, almost solely small to medium-sized arthropods, primarily adult and larval insects; frequency of stink-bugs (Pentatomidae) in stomachs notable. On migration and on non-breeding grounds takes arthropods and small fruits. Rarely, captures small lizards (*Cnemidophorus communis*, scincids) and rodents (small mouse). Fruits recorded include those of saguaro, cardón, organ-pipe cactus, and mistletoe (Viscaceae) berries.
Breeding. From Mar, laying mostly from mid-Apr; timing later in N of range; usually single-brooded, but sometimes two broods in low-elevation desert habitats in S. Nest mostly of dry grass, stems, rootlets and various other vegetable material, lined with wool, hair and other soft material, placed in natural or artificial cavity of wide variety of types; in 3-year study of 33 nests in cylindrical metal fence poles 6-14 cm in diameter along highways in SE Arizona, most were attached to internal projections but in some cases the birds filled pole to desired height. Clutch 2-7 eggs, mean 4·3 eggs; incubation by female, period c. 14-16 days; chicks fed by both parents, leave nest at 13-17 days; fledglings fed by parents for up to 2 weeks. In Arizona study, nine of 15 active nests had dead eggs or young and only 40% were possibly successful; temperature often greater than 41°C (highest 49°C), almost certainly lethal.
Movements. Some apparently resident in parts of extreme SE California and S Arizona, Baja California and Sonora. Otherwise migratory; winters on Pacific slopes from Mexico S to Honduras. Leaves breeding grounds mostly Aug-Sept; returns Mar-May, earliest in low-lying areas in S. Casual to S Canada, E USA (especially Alabama and Florida) and Bermuda.
Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population 8,900,000 individuals. Survey data show that the species increased by 94% overall between 1966 and 1993, with largest increases in the Sonoran Desert, Edwards Plateau, Chihuahuan Desert, Arizona, Utah and Texas; has been suggested that this apparent growth may be at least partly explained by earlier under-recording, although this thought unlikely by some authors. Local reductions and extinctions have occurred in response to habitat loss due to agriculture, urbanization, flood-control projects and planting of exotic vegetation in suburbs; very sensitive to loss of nesting cavities, both natural and artificial. At N of range US range, in Washington, preferred white oak (*Quercus garryana*) habitat is increasingly rare and local, and this tyrannid is now considered a "priority species" in the state. Loss and alteration of wooded habitats in wintering range may also have a negative effect.
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bent (1942), Cardiff & Dittmann (2002), Contreras (1997), Cory & Hellmayr (1927), Davis (1961), DeGraaf & Rappole (1995), Dunning & Bowers (1990), Fair & Myers (1998), Finch (1991), Fitzpatrick (1980a), Hejl *et al.* (1995), Howell & Webb (1995a), Johnsgard (1979), Joseph *et al.* (2004), Kaufman (1996), Lanyon (1961, 1963a, 1963b), Monroe (1968), Nelson (1904), Peterjohn *et al.* (1995), Price *et al.* (1995), Ridgway (1907), Root (1988), Sauer & Droege (1992), Slud (1964), Small (1994), Stiles & Skutch (1989), Stotz *et al.* (1996), Udvardy (1963).



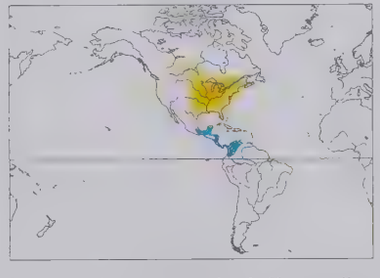
386. Nutting's Flycatcher

Myiarchus nuttingi

French: Tyran de Nutting **German**: Pazifischer Schopftyrann **Spanish**: Copetón de Nutting

Other common names: Pale-throated Flycatcher

Taxonomy. *Myiarchus nuttingi* Ridgway, 1882, La Palma de Nicoya, Guanacaste, western Costa Rica.
In the past sometimes considered conspecific with *M. cinerascens*, but differs in mouth-lining colour, vocalizations, rectrix pattern, wing formula, and morphometrics; no evidence of hybridization between the two. Nominate race intergrades with *flavidior* in S Mexico (Oaxaca), S Nicaragua and Costa Rica (Guanacaste), and with *inquietus* over larger zone in Oaxaca; all three races occur in both pure and hybrid forms in Oaxaca; complex pattern of zones of contact between races has not been assessed since 1961, and study urgently needed. Three subspecies recognized.
Subspecies and Distribution.
M. n. inquietus Salvin & Godman, 1889 - W & C Mexico (WC Sonora S to Chiapas, and E to S San Luis Potosí and Hidalgo).
M. n. nuttingi Ridgway, 1882 - arid interior valleys from S Mexico (Oaxaca and Chiapas) through Guatemala (R Motagua), Honduras (Choluteca and Comayagua Valleys) and W Nicaragua (arid slopes in vicinity of Matagalpa) to NW Costa Rica (tropical deciduous woodland of Guanacaste).
M. n. flavidior van Rossem, 1936 - Pacific lowlands of S Mexico (Oaxaca and Chiapas) S to NW Costa Rica.



Descriptive notes. 18-19 cm; 21-23·9 g. Plumage is drab grey-brown above, paler and greyer on head side, uppertail-coverts with variable rufescent tinge; wings browner, rufous outer edges of primaries, greyish-white outer edges of secondaries and tertials, pale tips of greater and median wing-coverts (two wingbars); rectrices, except central pair, with small amount of rufous on inner webs; throat and breast grey, contrasting yellow abdomen and undertail-coverts; bare parts dark; inside of mouth orange. Sexes similar. Juvenile has extensive rufous on central rectrices and tips of wing-coverts. Race *inquietus* is larger than others; *flavidior* has richer yellow abdomen. Voice. Sharp "wheek" or "wheep", shorter than calls of *M. crinitus*; dawn song a varied series of 1-3 or more sharp calls followed by short, often accelerating, rolled chatter.
Habitat. Tropical deciduous forest and thorn woodland; arid to semi-arid scrubby woodland, semi-open areas with scrub and small trees, and interior and edge of deciduous and evergreen forest and second growth. Sea-level to 1800 m.
Food and Feeding. Insects and berries. Usually hunts from understorey to medium heights. Sallies and hovers within foliage to snatch food items; less often, hawks flying insects. Recorded at army-ant swarms.
Breeding. Few data. Nest a cup of fur, feathers, catkins, and shed skin of snake or lizard, placed in cavity (e.g. in fence post) 0·3-1·2 m above ground. Clutch 3-5 eggs.
Movements. Resident. Occasional wandering; vagrants recorded in NE Sonora, also in S USA (S Arizona, California, possibly New Mexico).
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in Río Negro Jaguar Reserve and Tarcol Lodge, both in Costa Rica.
Bibliography. Anon. (1998a), Binford (1989), Bowers & Dunning (1987), Cory & Hellmayr (1927), Dickerman & Phillips (1953), Eisenmann (1955), Fitzpatrick (1980a), Fleming & Baker (1963), Gillespie & Walter (2001), Howell & Webb (1995a), Hutto (1992), Kaufman (1996), Land (1970), Lanyon (1961), McKee & Erickson (2002), Monroe (1968), Nelson (1904), Phillips (1960), Ridgway (1907), van Rossem (1936), Rowley (1984), Salvin & Godman (1892), Schaldach (1963), Slud (1964, 1980), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Vega-Rivera *et al.* (2003), Wetmore (1944), Zhang *et al.* (2003), Zimmerman (1978a).

387. Great Crested Flycatcher

Myiarchus crinitus

French: Tyran huppé **German**: Gelbbauch-Schopftyrann **Spanish**: Copetón Viajero

Taxonomy. [*Turdus*] *crinitus* Linnaeus, 1758, South Carolina, United States.
Phylogenetic analysis of mitochondrial DNA suggested that closest relatives are *M. yucatanensis*, *M. cinerascens* and *M. tyrannulus*, but relationships within this group not resolved. Birds from Massachusetts separated as race *boreus* on basis of bill size, but geographical variation considered clinal. Monotypic.
Distribution. Breeds S Canada (EC Alberta E to S Manitoba, extreme W & SE Ontario, S Quebec, New Brunswick, Nova Scotia, occasionally Prince Edward I) and E USA (from C North Dakota, NE & SW South Dakota, C Nebraska, NE Colorado, Oklahoma and S Texas); probably also extreme N Mexico (NE Coahuila). Winters in SE USA (S Florida), and S Mexico through Central America to N Colombia and NW Venezuela.

Descriptive notes. 21·5 cm; 27·2-39·6 g. Large, boldly marked *Myiarchus*. Plumage is olive-green above, crown with dark feather centres giving streaked appearance and producing some contrast with back; face and auriculars slightly greyer than crown; rufous-tinged uppertail-coverts; wings brown, outer edges of primaries margined with rufous, those of secondaries and tertials with greyish-white (a little yellower on tertials), inner edges of tertials light yellowish-cinnamon, greater and median wing-coverts broadly tipped greyish-white (two wingbars); central rectrices brown, others with innermost webs almost entirely rufous except for very narrow band of brown adjacent to and along length of rachis, outermost webs of outermost rectrices tending to pale greyish-white; throat and breast grey, sharply demarcated from bright yellow abdomen and undertail-coverts; upper flanks and side of lower breast occasionally washed green; tibial feathering olive-brown; underwing-coverts yellow; iris dark, bill dark with paler base to lower mandible, legs dark. Distinguished from *M. tyrannulus* and *M.*

On following pages: 388. Brown-crested Flycatcher (*Myiarchus tyrannulus*); 389. Galapagos Flycatcher (*Myiarchus magnirostris*); 390. Grenada Flycatcher (*Myiarchus nugator*); 391. Rufous-tailed Flycatcher (*Myiarchus validus*); 392. La Sagra's Flycatcher (*Myiarchus sagrae*); 393. Stolid Flycatcher (*Myiarchus stolidus*); 394. Puerto Rican Flycatcher (*Myiarchus antillarum*); 395. Lesser Antillean Flycatcher (*Myiarchus oberi*); 396. Flammulated Flycatcher (*Deltarhynchus flammulatus*).

cinerascens by fairly heavy bill, sharp contrast between dark grey chest and yellow belly, little contrast between face and olive crown, and inner webs of all but central rectrices entirely or largely cinnamon-rufous. Sexes similar, female slightly smaller than male. Juvenile is like adult but duller. Voice. Diagnostic vocalization a rising "wheee-eep" often given in excited series, "whee-up, wheee, whe-whe-whe-whe-wheeee-up!"; also, more modulated, rolling "whir-r-r-r-r-r-up". During courtship display, these calls given excitedly, often in syncopation, by both members of the pair perched less than 1 m apart, high in tree. Dawn song "wheee-up, whir-r-r-r-r-r-up" repeated over and over.

Habitat. Open deciduous woodlands and edges of clearings. Old orchards, wooded pastures and riparian corridors, wooded swamps, parks, cemeteries and urban areas with numerous large shade trees; isolated woodlots, second-growth woodlands, wooded hedgerows and selectively cut woodlands. Avoids boreal forest. Winters in wider range of wooded habitats, including borders and canopy of undisturbed humid forest, semi-arid forest and edge. In non-breeding season recorded to 1400 m in Costa Rica.

Food and Feeding. Insects and other invertebrates, also small berries and other fruits. Captures insects on wing by sallying from a perch, by outward hover-gleaning and by pouncing on ground from a perch.

Breeding. From Mar-Apr in S of range; later, from May-Jun, in N. Nest in natural or artificial cavity up to 1·8 m deep, filled with "trash"; nest constructed of leaves, petioles and wide variety of other fine plant matter, also hair, feathers, eggshell, pieces of shed snakeskin (incidence of snakeskin may vary geographically, often absent), and artificial materials such as paper and horse manure; natural cavity in dead tree preferred, but live tree, abandoned woodpecker (Picidae) hole and wide variety of artificial sites (pipe, lard bucket, tin can) also used. Clutch 4-8 eggs, usually 5; incubation by female (two records of male with apparent brood patch, presumably highly exceptional), period 13-15 days; chicks brooded by female, fed by both parents, leave nest at 13-15 days. Parasitized rarely by Brown Cowbird (*Molothrus ater*).

Movements. Migratory. Winters in SE USA (S Florida) and from S Mexico (S from S Veracruz and N Oaxaca) S to E Panama, also in W & N Colombia and NW Venezuela; rare in winter in Cuba and Bermuda, and reported also in NE Ecuador.

Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population 7,500,000 individuals. Breeding range has expanded, especially in Canada, for unknown reasons. Survey data reveal no apparent trend between 1966 and 1994, with slight increases and declines in different states of USA. Possible competition for nest-sites with several species, e.g. introduced Common Starling (*Sturnus vulgaris*), and lack of suitable nest-sites locally (owing to forestry practice of clearing out old trees).

Bibliography. Anon. 388. **Brown-crested Flycatcher**

Myiarchus tyrannulus

French: Tyran de Wied **German**: Braunschopftyrann **Spanish**: Copetón Tiranillo
Other common names: Wied's (Crested) Flycatcher, Rusty-tailed Flycatcher

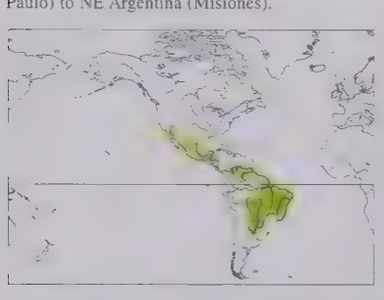
Taxonomy. *Muscicapa tyrannulus* Statius Muller, 1776, Cayenne.

Phylogenetic analysis of mitochondrial DNA places this species in a clade with *M. yucatanensis*, *M. crinitus* and *M. cinerascens*. It further suggests that *M. nugator* (formerly treated as conspecific) together with Caribbean, N Venezuelan and Colombian populations of present species may warrant separation at species level (as *M. erythrocercus*); also, that remaining populations of South America (nominate race and *bahiae*) belong to a different clade; additionally, that currently recognized races of North and Central America fall into a third clade (that may warrant recognition as *M. cooperi*). Morphological diversity among all populations is low. Possibility, nature and extent of any interaction and intergradation in Honduras and El Salvador between *cooperi* and *brachyurus* require study. Island taxa *cozumelae* and *insularum* weakly differentiated morphologically. Race *bahiae* reportedly intergrades with nominate. Revision needed of circumscription of this species and the races within it. Seven subspecies currently recognized.

Subspecies and Distribution.

M. t. magister Ridgway, 1884 - S USA (SE California, S Nevada and SW Utah, W, SC & SE Arizona, SW New Mexico) and W Mexico (S to Pacific slope of E Oaxaca).

M. t. cooperi S. F. Baird, 1858 - S USA (S Texas) and E Mexico (S to interior E Oaxaca and E to Quintana Roo) S to N Honduras.



M. t. insularum Bond, 1936 - Bay Is (Utila, Bonacca, Roatán), off N Honduras.

M. t. cozumelae Parkes, 1982 - Cozumel I.

M. t. brachyurus Ridgway, 1887 - W Nicaragua and NW Costa Rica.

M. t. tyrannulus (Statius Muller, 1776) - N & E Colombia and S Ecuador E to Trinidad and Tobago, the Guianas and mouth of Amazon, and S of Amazonia in N & E Peru, Bolivia, S Brazil, Paraguay and N Argentina.

M. t. bahiae Berlepsch & Leverkühn, 1890 - lower Amazon Basin S through E Brazil (S to São Paulo) to NE Argentina (Misiones).

Descriptive notes. 20 cm; male 28·3-29·8 g and female 27·1-32·5 g (N *tyrannulus*), male 27-30·4 g and female 22·2-30 g (S *tyrannulus*), 23·9-32 g (*bahiae*), male 36·4-52·5 g and female 40·3-46 g (*magister*), male 32·7-45 g and female 30·7-40·7 g (*cooperi*), 41·9-43·6 g (*insularum*), 31·4-33·1 g (*brachyurus*). Large *Myiarchus* with conspicuous rufous in tail, two broad whitish wingbars. Plumage is greyish-brown above lacking marked olive or green suffusion, no marked contrast between crown and back; face and side of neck grey; primaries edged rufous-brown, narrow white edge on outer webs of inner secondaries, outer webs of tertials and greater and median wing-coverts broadly edged whitish, edges of inner webs of tertials pale rufous; inner webs of all but central rectrices conspicuously marked with rufous-brown (tail brown from below); throat and breast pale grey, tending to more whitish on throat; lower underparts yellow, tibial feathering olive-brown, underwing-coverts yellow; iris dark, bill dark often with paler base to lower mandible, inside of mouth yellow, legs dark. Sexes alike. Races differ mainly in degree of shading of upperparts and in size: *bahiae* putatively has less or no rufous on inner webs of outer rectrices (but distinction from nominate not constant); *cooperi* is larger than nominate; *magister* is largest of all, with relatively long body and large bill, also brighter yellow below; *insularum* is darker than previous two, especially on breast; *cozumelae* is darker still; *brachyurus* is smallest of North and Central American races. Voice. In response to intrusion by conspecifics, emits series of "huit" notes, rasps and slowly modulated whistles and rapid "huit" notes; "huit" is the most conspicuous and variable element of vocal repertoire. Isolated "huit" notes a conspicuous characteristic of dawn song, alternated with complex phrases derived from combination of "whay-burg" and brief series of rapid "huit" notes.

Habitat. Forest edge and woodland, including lowland riparian woodland, thorn woodland, second growth, and columnar-cactus woodland; tropical deciduous forest, gallery forest (including understorey), secondary forest, arid lowland scrub, *cerrado*. Also in mangroves in Colombia, Honduras, El Salvador; riparian forest dominated by cottonwood (*Populus*) and willow (*Salix*) in Arizona (USA); viny canopy of humid tropical forest along lake and river margins in W Amazonia. Sea-level to 1700 m; in Venezuela, to 1100 m N of R Ocinoco and 300 m S of it; to 1000 m in arid and drier habitats in Colombia.

Food and Feeding. During breeding takes almost exclusively arthropods, primarily insects (e.g. cicadids); rarely, lizards (e.g. *Anolis*). More omnivorous in non-breeding season, taking small fruit as well as arthropods. Recorded attempting to catch hummingbirds (Trochilidae), possibly in response to drought-induced food scarcity. Observed while feeding on *Ocotea pulchella* (Lauraceae) in Brazil (São Paulo). In Amazonia, recorded as taking food by gleaning, mostly performing upward strikes, less often outward and upward hovers, and rarely perch-to-ground pounces. Recorded at army-ant swarms.

Breeding. Mar-Aug in North America; Jan-Jul and Oct-Nov in N South America and Oct-Dec in S. Cavity-nester; nest lined with typical material such as hair, fur, feathers, snakeskin and plant material; deserted woodpecker (Picidae) hole often used, also natural hole in columnar cactus or tree; and once recorded as nesting in metal pipe. Clutch mostly 3-5 eggs, always 5 in study in Argentina (Mendoza); no information on incubation period; fledging 15 days at one nest; chicks fed by both parents. Parasitized by Shiny Cowbird (*Molothrus bonariensis*) in Argentina.

Movements. Partially migratory in USA and Mexico, also in S South America (details of movements unresolved). N populations of *magister* and *cooperi* winter in respective S halves of breeding ranges, latter S to El Salvador. Present in much of N Bolivia only in austral winter; similarly, appears to be present in adjoining Brazil (Acre, Rondônia) and Peru mostly Jun to early Oct at latest, but a record in SE Peru in late Nov. Mexican populations are migratory; winter records from Yucatán mainland may be based in large part on migrants from N. Race *cozumelae* absent from Cozumel I in winter, but winter range unknown.

Status and Conservation. Not globally threatened. Fairly common to common. Estimated global population 7,700,000 individuals. Survey data show that US breeding population increased substantially between 1966 and 1993, even though habitat loss, especially destruction of riparian habitats, caused local declines or extinctions. Concern has been expressed that Californian populations may suffer nest-site competition from introduced Common Starlings (*Sturnus vulgaris*), but this flycatcher seems able successfully to defend its nests; other potential concerns are further habitat loss, effects of invasive plants and wildfires. On a global scale, however, this species has a very large range and occurs in numerous protected areas.

(1938), Zimmer, K.J. & Hilty (1997), Zimmer, K.J. *et al.* (1997).

389. **Galapagos Flycatcher**

Myiarchus magnirostris

French: Tyran des Galapagos **German**: Galapagosschopftyrann **Spanish**: Copetón de Galápagos
Other common names: Large-billed Flycatcher

Taxonomy. *Tyrannula magnirostris* Gould, 1839, no locality = Chatham Island, Galapagos Islands.

Was formerly placed in a monotypic genus, *Eribates*, on basis of supposed "very long tarsus". Morphologically, appears most closely related to *M. tyrannulus*, but it was not included in recent phylogenetic analysis; in playback experiments has shown behavioural response to voices only of that species and *M. nugator*, further suggesting a close relationship to the "*M. tyrannulus* group". Monotypic.

Distribution. Galapagos Is: present on all main islands.

Descriptive notes. 15-16 cm. The smallest *Myiarchus* (wing less than 80 mm), looking like a diminutive *M. tyrannulus*. Plumage is olive-green above, faint rufescent tinge on crown; wings brown, little or no rufous or pale greyish-white fringing except on greater and median wing-coverts, which diffusely tipped with greyish-white; tail brown, inner webs of rectrices conspicuously marked with brown (at least 3 mm wide in adult); throat and breast grey, abdomen and undertail-coverts pale yellow, tibial feathering olive-brown; underwing-coverts yellow; iris dark, bill and legs dark. Sexes similar. Juvenile has rufous-tipped wing-coverts. Voice. Vocal responses to intruding conspecifics repeated "huit" notes, slowly vibrato-modulated whistles; dawn song principally a repeated complex phase with introductory "whay-burg" note and series of rapid "huit".

Habitat. Arid scrubland with cacti (*Opuntia*, *Jasminocercus*) and trees (*Bursera*, *Prosopis*); occasionally around saline coastal lagoons. Found from sea-level (rocks at high-tide line) to grassy areas (*Paspalum*) on mountaintops above 900 m; recorded to 1500 m.
Food and Feeding. Insects. Seen to feed in a large tree with red flowers (*Erythrina velutina*), but food items not noted. One record of moths (Lepidoptera) being fed to partially fledged young. Perches at all heights in vegetation, but frequently within 2 m of ground; sallies to ground for prey, and even settles on ground to search upward into overhanging vegetation, much more than other members of genus.
Breeding. Breeds Dec-Mar. Nest in cavity and lined with feathers, fur, small twigs and other plant matter, also hair; small sticks, particularly of *Cryptocarpus pyriformis*, crushed by cars on roadsides are often taken as nest material; chicken feathers commonly used; in one study, nests 1·5-3 m above ground in large cactus (*Opuntia echios*) or in hollow limb of *Jasminocereus howellii*, or to 6 m in citrus and other trees; of 18 nests found in one year, ten were in cactus, seven in electricity poles, and one in hood of a raincoat draped over interior half-wall inside a house; nests in native vegetation were all more than 100 m apart. Clutch 3-5 eggs, possibly once 6; no information on incubation and fledging periods. In one study of 18 nests, all but one were unsuccessful; nests lacking protection are abandoned after heavy rain.
Movements. Sedentary. One record of an individual on board a ship off Wolf I.
Status and Conservation. Not globally threatened. Restricted-range species: present in Galápagos Islands EBA. Entire range a national park, formally protected as a Biosphere Reserve and World Heritage Site. Has adapted well to human presence and urban environments. Concern has been expressed that avain populations generally on San Cristóbal (where this species occurs) might be susceptible to avian pox and crop canker (*Trichomanes gallinae*); an early report of "featherless swellings or tumours" at base of mandible; more data needed in order to place putative declines, which in some species have led to extinction on San Cristóbal, into longer-term perspective. In some areas, natural habitats threatened by overgrazing and fires, and the species may suffer some losses to introduced predators.
Bibliography. Butler (1979), Castro & Phillips (1996), Cory & Hellmayr (1927), Ervin (1992), Fitzpatrick (1985a), Gifford (1919), Harris (1973, 1982), Heinzel & Hall (2000), Joseph *et al.* (2004), Lanyon, W.E. (1985, 1978), Nelson (1968), Ridgway (1907), Rothschild & Hartert (1899), Salvin (1876), Sherborn (1897), Stotz *et al.* (1996), Swarth (1931), Swash & Still (2000), Vargas (1996).

390. Grenada Flycatcher

Myiarchus nugator

French: Tyran bavard **German**: Grenadaschopftyrann **Spanish**: Copetón de Granada

Taxonomy. *Myiarchus oberi nugator* Riley, 1904, Grenada, Lesser Antilles.
Phylogenetic analysis of mitochondrial DNA nested this species within *M. tyrannulus*; it further suggested that Caribbean, N Venezuelan and Colombian populations of latter, combined with present species, may warrant separation at species level (as *M. erythrocercus*). Was often treated in earlier literature as a race of *M. tyrannulus*; differs in bright orange inside of mouth, but is otherwise weakly differentiated. Monotypic.
Distribution. St Vincent, the Grenadines and Grenada, in S Lesser Antilles.

Descriptive notes. 20 cm; 37 g. Large *Myiarchus* with large bill. Plumage is brownish-grey above, with no marked olive or olive-green suffusion; outer webs of primaries edged cinnamon, outer webs of secondaries, tertials and greater and median wing-coverts broadly edged pale whitish, tending more fuscous on coverts (two pale brown wingbars); inner webs of all but central pair of rectrices conspicuously marked with rufous-brown (tail brown from below); throat and breast grey, tending paler on throat; abdomen and undertail-coverts washed-out lemon-yellow, tibial feathering olive-brown; iris dark, bill dark, inside of mouth bright orange, legs dark. Differs from *M. oberi* in having orange (instead of pale yellow) inside mouth, and most of secondaries fringed with grey or pale cream (instead of cinnamon). Sexes similar. Juvenile is probably duller than adult. Voice. Vocalizations lack prolonged plaintive whistles of Lesser Antillean congeners; also described as a loud "quip" or harsh "quek".
Habitat. Tropical lowland evergreen forest, secondary forest; open areas around settlements, especially near palms. Sea-level to 900 m.
Food and Feeding. Sallies into open to catch insects, often returning to same perch.
Breeding. Breeds Mar-Oct; gonads enlarged in late Mar, regressed in Jul. Nest in tree cavity, sometimes in open pipe. Clutch size 2-4. No other information.
Movements. Presumably sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Lesser Antilles EBA. Common. Islands of Lesser Antilles have suffered large-scale destruction of forests as a result of agricultural and tourist development; destruction less severe on the mountainous islands, where forests more inaccessible. Several reserves exist within the species' range, but most are relatively small.
Bibliography. Anon. (1998a), Bond (1956b), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), Faaborg (1985), Joseph *et al.* (2004), Lanyon (1967b), Raffaele *et al.* (1998, 2003), Ridgely & Tudor (1994), Ridgway (1907), Stotz *et al.* (1996).

391. Rufous-tailed Flycatcher

Myiarchus validus

French: Tyran à queue rousse **German**: Rostschwanz-Schopftyrann **Spanish**: Copetón Colirrufo

Taxonomy. *M[yiarchus] validus* Cabanis, 1847, "one of the West Indian islands" = Jamaica.
Formerly placed in a monotypic genus, *Hylonax* (and inadvertently in family Cotingidae), largely on basis of putatively distinctive non-exaspidean tarsus; tarsal scutellation, however, variable within present genus. Phylogenetic analysis of mitochondrial DNA places this species firmly within current genus, as basal sister to a radiation of primarily Caribbean and Central and North American taxa. Monotypic.
Distribution. Jamaica.
Descriptive notes. 24 cm; 38·6-43·2 g. Has crown smoky brown with, at most, faintly darker feather centres; face and lores slaty greyer; upperparts dull olive, contrasting with darker crown,

uppertail-coverts tinged rufous; outer webs of primaries and secondaries with broad (c. 2 mm) band of rufous, tertials have broader (3 mm) band on outer webs and with inner webs almost wholly suffused with rufous (some darker brown only on proximal parts of webs), greater and median wing-coverts broadly tipped rufous (wing appears mainly rufous when bird perched); all rectrices except central pair mostly rufous, with darker brown confined to thin band adjacent to and running along length of rachis, outer webs of central rectrices paler, outermost rectrix almost entirely rufous except for narrow band of darker brown adjacent to rachis on distal half; throat and breast dark grey and abdomen and undertail-coverts yellow, but strong greyish wash on upper breast (making demarcation between breast and abdomen indistinct); tibial feathering olive-brown, underwing-coverts rufous; iris dark, bill dark with paler base to lower mandible, inside of mouth bright orange, legs dark. Distinguished from *M. barbirostris* and *M. stolidus* by generally rufous wings, larger size. Sexes similar. Juvenile has whitish underparts. Voice. Distinctive short, piercing whistled notes, "pree-ee-ee-ee-ee" like the neigh of a horse, given frequently in territorial defence, with occasional disyllabic "wick-up" or clicking note; dawn song undescribed.
Habitat. Various forest types and wooded hills; also dry scrub and secondary forests. Primarily middle elevations, above c. 300 m, to 2000 m; less frequently at highest elevations.
Food and Feeding. Feeds on fruits and insects; latter include cicadas (Cicadidae) and moths and butterflies (Lepidoptera). Sallies for prey from perches in dense vegetation beneath canopy.
Breeding. Breeds Apr-Jul; gonads small/regressed in Jul and Aug. Few reports of nests; materials include grass and leaves (no reports of snakeskin), placed in cavity or stump of tree; old reports of supposedly unusual placement in fork or indentation or decayed hollow near top of tree probably fall within range of variation expected of genus. Clutch 3 or 4 eggs, sometimes 5. No other information.
Movements. Presumably sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA. Fairly common. Was apparently particularly common in interior of St Ann and Trelawny Parishes in first half of 20th century. In Jamaica, 75% of original forest cover has already been cleared, and remaining forest largely second growth; undisturbed forest survives only on high steep mountain slopes, some of which are protected in the Blue Mountain and John Crow National Park, but hunting and habitat destruction continue because of lack of funds for protection and management. Resurgence in coffee cultivation during last 20 years has led to clearance of much second growth; other problems include hurricane damage, widespread pesticide use, establishment of pine (*Pinus*) plantations, timber removal, deliberate fires, and continuing conversion for small-scale farming and urbanization. Not known whether recent habitat change has constricted the range.
Bibliography. Anon. (1998a), Bond (1956b, 1985), Cory & Hellmayr (1927), Faaborg (1985), Joseph *et al.* (2004), Lanyon, W.E. (1967b, 1985), March (1863), Pregill *et al.* (1991), Raffaele *et al.* (1998, 2003), Ridgway (1905, 1907), Stotz *et al.* (1996).

392. La Sagra's Flycatcher

Myiarchus sagrae

French: Tyran de La Sagra **German**: Kubaschopftyrann **Spanish**: Copetón de De La Sagra
Other common names: Cuban Crested Flycatcher (*sagrae*); Bahama Flycatcher (*lucaysiensis*)

Taxonomy. *Muscicapa sagrae* Gundlach, 1852, Cuba.
Has been considered conspecific with *M. stolidus*, but usually treated as separate species on basis of vocal characters. Phylogenetic analysis of mitochondrial DNA found nominate race to be more closely related to nominate race of *M. stolidus*, with race *dominicensis* of latter being sister to race *lucaysiensis* of present species. Interestingly, dawn song of nominate *M. stolidus* is similar to that of both races of present species. Two subspecies recognized.
Subspecies and Distribution.
M. s. lucaysiensis (H. Bryant, 1867) - Bahamas (Abaco, Andros, Grand Bahama, Green Cay, Inagua, New Providence).
M. s. sagrae (Gundlach, 1852) - Cuba, I of Pines and Grand Cayman I.

Descriptive notes. 19-22 cm; 17-21g. Has unusual leaning posture and flat-headed appearance. Nominate race has crown smoky olive-brown, slightly lighter on forecrown, and contrasting with more olive-brown back, mantle and scapulars; uppertail-coverts slightly more rufescent than back; wings brown, outermost webs of primaries thinly margined with rufous, outermost edges of secondaries and tertials pale greyish-white (tending paler on tertials), greater and median wing-coverts diffusely tipped greyish-white (indistinct wingbars); tail mainly brown, rufous usually confined to rectrices 2 to 5 and most marked on 3 and 4; lores, throat, breast and upper abdomen pale ashen grey, perhaps slightly darker on lores; lower abdomen and undertail-coverts whitish, tending to yellower on undertail-coverts and lower flanks, tibial feathering olive-brown; underwing-coverts pale yellow, not so white as most of underparts (except perhaps undertail-coverts); iris dark, bill dark sometimes dusky, inside of mouth pale yellow, legs dark. Sexes similar. Juvenile likely with pale tips of wing-coverts either reduced or slightly tending to rufous, and more rufous in outer webs of outer rectrices. Race *lucaysiensis* is larger than nominate, has rufous in outermost rectrices, perhaps paler wingbars. Voice. No unmodulated, prolonged whistle in vocal repertoire. Nominate race song "weeet-ze-weer", call "huit". Race *lucaysiensis* dawn song a combination of modified "huit" note and rolling "brrr-r-r" with no whistled element.
Habitat. Pine (*Pinus*) woodland, scrub, evergreen forest, mixed woodland, dense thickets, mangroves and forests; at all available elevations, maximum recorded 1500 m.
Food and Feeding. Caterpillars, katydids (Tettigoniidae), other insects; also fruits and seeds. Typically, forages in understorey, mainly by snatching prey during hovering flights.
Breeding. Breeds Apr-Jul. Nest a cup of hair, feathers, plant fibres and other soft materials, in cavity of trunk, broken tree limb or bamboo stalk. Clutch 2-4 eggs. No other information.

Movements. Resident. Some wandering or dispersive movement; since early 1980s, race *lucaysiensis* recorded as vagrant in SE USA (Florida) in autumn, spring and winter (e.g., Biscayne National Park, Palm Beach, Birch State Park).
Status and Conservation. Not globally threatened. Common in most of range; uncommon in S Bahamas. Susceptible, at least on smaller islands, to natural and anthropogenic habitat loss, such as that caused by hurricanes and deliberate habitat destruction.
Bibliography. Anon. (1998a), Bangs (1916), Barbour (1943), Bradley (1985, 2000), Brudenell-Bruce (1975), Bryant (1867a), Buden (1987a), Cory & Hellmayr (1927), Emlen (1977), Faaborg (1985), Garrido & Kirkconnell (2000), Gundlach (1873), Joseph *et al.* (2004), Lanyon, W.E. (1967b, 1985), Miles (1967), Mlodinow & O'Brien (1996), Olson & Hilgartner (1982), Raffaele *et al.* (1998, 2003), Ridgway (1907), Robertson & Biggs (1983), Smith & Evered (1992), Stotz *et al.* (1996), Sánchez *et al.* (2003), White (1998).

393. Stolid Flycatcher
Myiarchus stolidus

French: Tyran grosse-tête **German**: Haitischopftyrann **Spanish**: Copetón Bobito

Taxonomy. *Myiobius stolidus* Gosse, 1847, Jamaica.
Has been considered conspecific with *M. sagrae*, but usually treated as separate species on basis of vocal characters. Phylogenetic analysis of mitochondrial DNA found nominate race to be more closely related to nominate race of *M. sagrae*, with race *dominicensis* as sister to race *lucaysiensis* of latter. Interestingly, dawn song of nominate race is similar to that of both races of *M. sagrae*. Two subspecies recognized.
Subspecies and Distribution.
M. s. stolidus (Gosse, 1847) - Jamaica.
M. s. dominicensis (H. Bryant, 1867) - Hispaniola (Haiti, Dominican Republic) and adjacent islands (Gonâve, Tortue, Grande Cayemite, Beata).

Descriptive notes. 20 cm; 19·3-26·3 g. Dark-backed *Myiarchus* with prominent wingbars. Nominate race has crown olive-green, only slightly (if at all) darker than back, mantle and scapulars; uppertail-coverts slightly lighter than rest of dorsal surface; face and lores similarly dark; wings brown, weak rufous outer edging on primaries, pale greyish-white outer edges of secondaries and tertials, greater and median wing-coverts broadly tipped pale greyish-white (two clear wingbars); tail brown, rufous on inner webs of all rectrices except outermost (sometimes present on proximal part of outermost); throat and breast ashen grey, abdomen and undertail-coverts yellow, variably demarcated from grey of breast; tibial feathering olive-brown; iris dark, bill dark, mouth-lining pale orange, legs dark. Sexes similar. Juvenile probably has rufous tips on wing-coverts. Race *dominicensis* is very like nominate, but rufous on inner webs of all rectrices (including outermost), throat and breast perhaps slightly darker. Voice. Dawn song shows some similarity to those of *M. sagrae* (of both races), middle and terminal components virtually idenical, introductory note is whistled. Prolonged and ascending whistled note a diagnostic part of daytime repertoire; also various other disyllabic and typical rasps, rolls and "huit" notes. Plaintive "jui" (*dominicensis*).
Habitat. Lowland forest and forest edges; arid woodland, scrub and mangrove forest. Pine (*Pinus*) woods and remnant pine forests but not in coffee plantations on Hispaniola. Less frequently in edges of wet mid-elevation forest. To at least 1800 m.
Food and Feeding. Insects captured from a twig or leaf while in flight, by outward hover-gleaning. Also, fruits plucked while hovering.
Breeding. Breeds Apr-Jun; gonads regressed in Jul and Aug. Nest in cavity in tree or in artificial structure (e.g. house). Clutch 3 or 4 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA and Hispaniola EBA. Common. In Jamaica, 75% of original forest cover already cleared, and remaining forest largely second growth; undisturbed forest only on high steep mountain slopes, some of which are protected in the Blue Mountain and John Crow National Park, but hunting and habitat destruction continue because of lack of funds for protection and management. Resurgence in coffee cultivation during last 20 years has led to clearance of much second growth. Haiti is one of the world's most environmentally degraded countries, with remaining forests covering less than 1·5% of the land area, and only c. 10% of forests remain in Dominican Republic; there are only two small national parks in Haiti and c. 22 protected areas (and 15 new areas proposed) covering c. 16% of the land area in Dominican Republic, but lack of funds threaten their long-term survival. Habitat loss continuing throughout this species' range; problems include hurricane damage, widespread pesticide use, plantations of exotic trees, timber removal, deliberate fires, and continuing conversion for small-scale farming and urbanization.
Bibliography. Anon. (1998a), Bond (1928a, 1985), Bryant (1867b), Cory (1885), Cory & Hellmayr (1927), Dod (1987), Faaborg (1985), Gosse (1847), Joseph *et al.* (2004), Keith *et al.* (2003), Lanyon (1967b), Pregill *et al.* (1991), Raffaele *et al.* (1998, 2003), Ridgway (1907), Stotz *et al.* (1996), Wetmore & Swales (1931), Wunderle & Latta (1996).

394. Puerto Rican Flycatcher
Myiarchus antillarum

French: Tyran de Porto Rico **Spanish**: Copetón Puertorriqueño
German: Puerto-Rico-Schopftyrann

Taxonomy. *Tyrannus antillarum* H. Bryant, 1866, Puerto Rico.
Phylogenetic analysis of mitochondrial DNA indicates that this species is sister to *M. oberi*. Monotypic.
Distribution. Puerto Rico, Vieques, Culebra, and Virgin Is (St Thomas, St John, Tortola, Virgin Gorda).
Descriptive notes. 18·5-20 cm; 22-25·3 g. Most white-bellied *Myiarchus*, also with no rufous in tail. Crown is smoky olive-brown, contrasting with plainer brown back, mantle and scapulars; uppertail-coverts slightly more rufescent than back; outer edges of primaries rufous, outer edges of secondaries and tertials paler greyish, becoming increasingly paler on the tertials, greater and median wing-coverts broadly tipped greyish-white; tail brown, paler on outermost webs of outer

rectrices, rufous (when present) confined to tips on inner webs of most feathers; throat and breast ashen grey, streaked paler whitish-grey, pale grey extending to lores (which are nonetheless darker than throat); abdomen and undertail-coverts very pale yellowish-white, not well demarcated from breast, brownish wash on side of lower breast; tibial feathering olive-brown; underwing-coverts pale whitish-yellow; iris dark, bill dark, mouth-lining pale yellow, legs dark. Sexes similar. Juvenile probably has rufous tipping on wing-coverts. Voice. Distinctive plaintive whistle, "whee", not ascending but sometimes descending. Dawn song like that of *M. stolidus*, but terminal element not modulated. Dissyllabic "wick-up" is middle element of dawn song, and given during day.
Habitat. Tropical deciduous forest, arid lowland scrub, mangrove forest and borders, tropical lowland evergreen forest, coffee plantations, citrus groves. Sea-level to 800 m.
Food and Feeding. Mainly insects; also seeds and berries. Stomach contents of 40 birds in Dec-Aug c. 84% animal matter and 16% plant matter: Hemiptera, weevils (Curculionidae) and caterpillars comprised bulk of animal food, which also included orthopterans, various coleopterans, hymenopterans, Mollusca, also single specimens with *Anolis* lizard and *Eleutherodactylus* frog; dominant vegetable matter mainly seeds of wild fruits or berries, and one bird had eaten 36 grass seeds (*Paspalum*). Inconspicuous and inactive, often noticed only by voice. Foraging techniques not well known; insects at least sometimes captured on wing.
Breeding. Recorded Feb-Jun; inspecting nest holes in latter part of Apr and May; three recently fledged young seen in early Jul. Nest of plant stems, lined with finer materials (shed snakeskin not recorded), built in tree cavity or open stump; nestbox also used. Clutch 3-5 eggs; no information on incubation and fledging periods. In one study, 11 of 13 nests were parasitized by Shiny Cowbird (*Molothrus bonariensis*), and 13 young fledged from total of 41 eggs laid (mean clutch size 3·2); in another study, using nestboxes that virtually excluded predators, no reported parasitism, and mean clutch size 4·58; of 114 eggs recorded over two seasons in a further study, 103 (90·3%) hatched.
Movements. Presumably sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA. Common in Puerto Rico, fairly common on Vieques; in Virgin Is, uncommon on St John and rare on Culebra, St Thomas, Virgin Gorda and Tortola. Occurs in Guanica International Biosphere Reserve, in Puerto Rico. Susceptible to habitat loss due to either natural (hurricanes) or anthropomorphic (vegetation clearance) causes and, potentially, to brood parasitism. Declines in populations on Puerto Rico and Vieques had been attributed to 1928 hurricane (nearly extirpated from former), but has since recovered. Only 15 individuals recorded on St Thomas in 1943. Has declined in the Virgin Islands following habitat destruction. High rates of brood parasitism by Shiny Cowbirds have been documented.
Bibliography. Anon. (1998a), Biaggi (1983), Bond (1956b, 1985), Cory & Hellmayr (1927), Faaborg (1985), Joseph *et al.* (2004), Lanyon, W.E. (1967b, 1985), McCandless (1958), Raffaele (1989), Raffaele *et al.* (1998, 2003), Ridgway (1907), Staicer *et al.* (1996), Stotz *et al.* (1996), Torres Báez & Collazo (1992), Wetmore (1916), Wiley (1985, 1988).

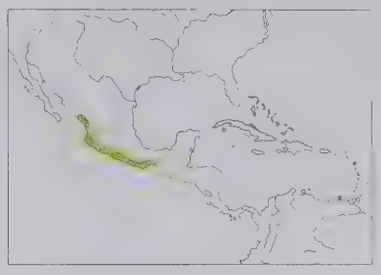
395. Lesser Antillean Flycatcher
Myiarchus oberi

French: Tyran janeau **German**: Kleinantillen-Schopftyrann **Spanish**: Copetón de Ober
Other common names: Guadeloupe Flycatcher (*oberi*)

Taxonomy. *Myiarchus Oberi* Lawrence, 1877, Dominica, Lesser Antilles.
Phylogenetic analysis of mitochondrial DNA indicates that this species is sister to *M. antillarum*; further, unpublished analysis also suggests that race *sclateri* is sister to the other three races. Earlier authors treated *sanctaeluciae* as a race of *M. tyrannulus* and *sclateri* as a race of *M. stolidus*. General clinal increase in size from N to S, but this this pattern "disrupted" on Martinique (*sclateri*). Four subspecies currently recognized.
Subspecies and Distribution.
M. o. berlepschii Cory, 1888 - St Kitts, St Christopher, Nevis and Barbuda.
M. o. oberi Lawrence, 1877 - Guadeloupe and Dominica.
M. o. sclateri Lawrence, 1879 - Martinique.
M. o. sanctaeluciae Hellmayr & Seilern, 1915 - St Lucia.

Descriptive notes. 19-22 cm; 23·3-37 g. Nominate race has crown and upperparts dark olive-green, uppertail-coverts with rufous edges; lores (especially), auriculars and face slightly greyer; wings brown, prominent rufous outer edges of primaries and inner edges of tertials, outer edges of secondaries and tertials slightly paler rufous, greater and median wing-coverts diffusely tipped greyish-white or rufous (faint wing-bars); outer webs of inner vanes of rectrices all with broad rufous stripe; throat and breast grey, tending to be paler on throat, rest of underparts yellow, washed greenish on flanks, and not sharply demarcated from grey of breast; tibial feathering olive-brown; underwing-coverts yellow; iris dark, bill dark, inside of mouth pale yellow, legs dark. Sexes similar. Race *sclateri* is most distinctive, smaller than others, lacks rufous in tail, wingbars perhaps least pronounced; *sanctaeluciae* is larger than nominate; *berlepschii* is smaller than previous, perhaps with paler yellow belly than nominate (and belly tends to be slightly richer yellow on Barbuda than on St Kitts and Nevis). Voice. Loud, prolonged plaintive whistles and also short whistles; dawn song like that of *M. antillarum*, but differing in lower frequency of whistled components and in configuration of "wick-up" note. Some individuals identifiable only by vocal characters.
Habitat. Primarily edges and canopy of dense woodland, "modified" thorn-scrub, forests and tree plantations at or above 100 m; much less frequently in second growth or scrub at lower levels. Recorded to 900 m.
Food and Feeding. Insects and small fruit. Perches vertically for medium to long periods amidst vegetation, bowing head to peer about in search of prey; takes insects primarily by hover-gleaning, also with upward strikes and short aerial sallies.

Breeding. Breeds Mar-Jul. Loose nest of plant fibres, feathers and plant down, built in tree cavity; suggestion of building cup-like nest in tree fork (instead of cavity) not wholly reliable. Clutch 3 to 4 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Lesser Antilles EBA. Generally common; rare on Guadeloupe. Islands of Lesser Antilles have suffered large-scale destruction of forests through agricultural and tourist development, less severe on the mountainous islands with inaccessible areas. Several reserves exist, but most are relatively small. Susceptible to habitat loss through both natural (hurricane damage) and anthropogenic (vegetation clearance) causes.
Bibliography. Anon. (1998a), Anthony (1997), Benito-Espinal & Hautcastel (1988), Bond (1956b), Cory & Hellmayr (1927), Faaborg (1985), Feldmann *et al.* (1998), Hellmayr & Seilern (1915), Keith (1997), Lanyon (1967b), Noble (1916), Pinchon (1963), Raffaele *et al.* (1998, 2003), Ridgway (1907), Stotz *et al.* (1996).



Genus *DELTARHYNCHUS* Ridgway, 1893

396. **Flammulated Flycatcher**

Deltarhynchus flammulatus

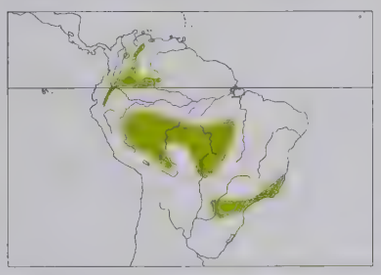
French: Tyran flammé **German**: Breitschnabel-Schopftyrann **Spanish**: Copetón Abejerillo

Taxonomy. *Myiarchus flammulatus* Lawrence, 1875, Cacoprieto, Oaxaca, southern Mexico.
Affinities uncertain; no molecular phylogenetic studies have yet included this genus. Currently considered closest to *Ramphotrigon*, differing in syringeal characters. Monotypic.
Distribution. Incompletely known. SW & S Mexico, from S Sinaloa S to Chiapas; populations in CW Chiapas (between El Sumidero and Tuxtla Gutiérrez, in Atlantic drainage of Cuenca Central) likely isolated from those along Pacific coast. Possibly also in Guatemala.
Descriptive notes. 15-16·5 cm; 17·2-20·5 g. Diminutive *Myiarchus*-like flycatcher with distinctive pale supraloral stripe, broken ocular ring, and streaked throat and chest. Plumage is olive-

green above, slightly darker greyish-olive on forecrown, faint nuchal collar; uppertail-coverts brown with broad rufous-cinnamon edges; wing feathers (except tertials) and tail feathers brownish, all broadly edged cinnamon, tertials edged lighter grey-brown; throat whitish and breast grey, both with dusky streaks, rest of underparts pale yellowish; tibial feathering olive-brown; iris dark, bill dark sometimes with pale base to lower mandible, inside of mouth orange, legs dark grey. Sexes similar. Juvenile has broader cinnamon edges on rectrices. Voice. In response to intruding conspecifics, emits a variety of pulsed notes, with sustained whistles, and with combinations of these two vocalizations. Dawn song various phrases each c. 1 second in length, given at intervals of 3 seconds, each phrase introduced by one of the daytime whistles, sometimes of a piercing variety and sometimes of the longer, more melancholic variety; the two types of whistles typically alternated.
Habitat. Dry deciduous woodland. Open thorny woodland dominated by mesquite (*Prosopis*) and acacia (*Acacia*), arid to semi-arid thorn-forest and scrubby woodland; coffee plantations. Sea-level to 1400 m.
Food and Feeding. Insects. Forages by outward hover-gleaning, similar to technique of *Myiarchus*.
Breeding. Recorded as carrying nesting material, copulating and laying in Jun. Single published description of cup-shaped nest, lining comprising solely fine vegetable fibres and small fragments of dried leaves and shredded bark (thus, unlike that of *Myiarchus* nests), in cavity but with incubating bird clearly visible (thus, much shallower than is normal for *Myiarchus*). Clutch 3 eggs (markings identical to those of *Myiarchus*). No other information.
Movements. Probably sedentary
Status and Conservation. Not globally threatened. Fairly common. Relatively poorly known; apparently disjunct distribution suggests that closer study of ecology and distribution is warranted.
Bibliography. Anon. (1998a), Binford (1989), Blake, E.R. (1953), Cory & Hellmayr (1927), Eisenmann (1955), Fitzpatrick (1980a), Howell & Webb (1995a), Hutto (1992), Lanyon, W.E. (1982b, 1985), Ridgway (1893, 1907), Salvin & Godman (1892), Schaldach (1963), Stotz *et al.* (1996).

PLATE 46

inches 4
cm 10



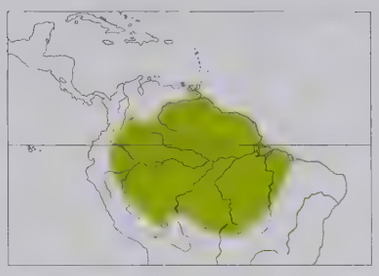
Genus *RAMPHOTRIGON* G. R. Gray, 1855

397. Large-headed Flatbill

Ramphotrigon megacephalum

French: Tyran mégacéphale **Spanish**: Picoplano Cabezón
German: Gelbbrauen-Breitschnabeltyrann
Other common names: Bamboo Flatbill

Taxonomy. *Tyrannula megacephala* Swainson, 1835, São Paulo, Brazil.
Present genus formerly believed to be allied to flatbills (*Tolmomyias* and *Rhynchocyclus*), but apparently belongs instead with *Myiarchus* and relatives, based on cranial, syringeal and nesting characters; molecular data still lacking. Present species formerly placed in genus *Tolmomyias*. Four subspecies recognized.
Subspecies and Distribution.
R. m. venezuelense Phelps, Sr & Gilliard, 1941 - NW Venezuela (W Trujillo, W Apure, W Barinas, NE Yaracuy, N Aragua), and probably into adjacent Colombia.
R. m. pectorale J. T. Zimmer & Phelps, Sr, 1947 - S Venezuela, SE Colombia and E Ecuador, probably also adjacent Brazil and Peru.
R. m. bolivianum J. T. Zimmer, 1939 - E Peru (S Loreto, Ucayali, Cuzco, Madre de Dios), Brazil (Amazonas, Mato Grosso and Pará S to Acre and Rondônia) and N Bolivia (Beni, La Paz, Cochabamba, NE Santa Cruz).
R. m. megacephalum (Swainson, 1835) - SE Paraguay (Canendiyu, Alto Paraná), NE Argentina (Misiones) and SE Brazil (E Minas Gerais and Espírito Santo S to São Paulo).



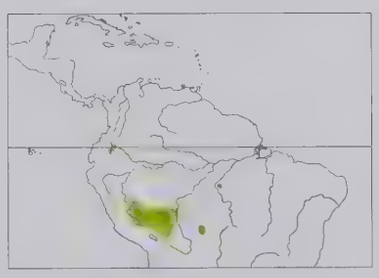
Descriptive notes. 12·5-13·2 cm; 13-15 g. Brown eye, flat black bill with basal third of lower mandible flesh-coloured, grey legs, slightly heavy-headed appearance. Has dark olive crown and upperparts, distinctive whitish to yellowish supraloral, eyering and faint postocular contrasting with dusky lores; wings and tail dusky, two prominent ochraceous wingbars, yellow-olive edging on flight-feathers and rectrices; whitish to yellowish throat, greyish-olive breast with faint yellowish streaks, pale yellow belly. Differs from *R. fuscicauda* in smaller size, slightly paler coloration, distinctive pale supraloral. Sexes alike. Race *venezuelense* darker than nominate, wing markings more cinnamon; *pectorale* has browner breast and more extensive yellow on belly; *bolivianum* has browner chest and duller yellow belly than nominate, top of head plain dusky greenish without pale markings. Voice. Call a soft mournful "wheé-whoo" (or "bam-boo") whistle, second note a semitone lower-pitched, heard throughout day, mostly in early morning and late afternoon, at intervals of 5-10 seconds; dawn song a continuous, rapidly uttered series of "tee-tu-twit" or "whu hu-hoowhip" whistles.
Habitat. Inside or at edge of humid seasonally inundated forest, usually closely associated with dense bamboo thickets and nearby dense understorey; also found in introduced Asian bamboo in disturbed plantations, e.g. in N Venezuela. To 1400 m.
Food and Feeding. Insectivore. Usually feeding alone, occasionally in mixed-species flocks. Perches quietly, and almost motionless, for long periods; then uses short forward or upward sallies to hover-glean prey from foliage or branches in relatively dense forest understorey to mid-storey, occasional aerial sallies.
Breeding. Nest and nestlings in Nov in Peru and juveniles in Nov-Dec in SE Brazil. Builds nest with ample material inside hole or cavity, e.g. one nest inside broken-off stump 1 m high, 10 cm deep and 6·5 cm wide. Clutch 2 eggs. No other information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to fairly common but very local. In seemingly disjunct populations in NW, C & CE South America. Much of its habitat remains in relatively pristine condition within its relatively large range. Occurs in many national parks and other protected areas.
Bibliography. Aleixo (1997), Aleixo *et al.* (2000), Allen (1995), dos Anjos *et al.* (1997), Bates & Parker (1998), Bates *et al.* (1998), Blake (1962), Brooks *et al.* (1993), Cadena *et al.* (2000), Canevari *et al.* (1991), Carrión & Sibley (1992), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Graves (1988b), Ferreira de Vasconcelos (2003), Fitzpatrick (1980c, 1985a), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Karr *et al.* (1990), Kratter (1997), Lanyon (1988a), Lowen *et al.* (1996), Madroño & Esquivel (1997), Mazar Barnett *et al.* (1997), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Pacheco (1995), Pacheco & Laps (2001), Parker (1984), Parker & Goerck (1997), Parker, Donahue & Schulenberg (1994), Parker, Stotz & Fitzpatrick (1997), de la Peña (1988), Peres & Whittaker (1991), Remsen & Parker (1995), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1968), Sharpe *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer, J.T. (1939c), Zimmer, K.J. *et al.* (1997).

398. Rufous-tailed Flatbill

Ramphotrigon ruficauda

French: Tyran rougequeue **Spanish**: Picoplano Colirrufo
German: Rostschwanz-Breitschnabeltyrann

Taxonomy. *Platyrhynchus ruficauda* Spix, 1825, "in sylvis fluminis Amazonum" = apparently mouth of River Madeira, Brazil.
Present genus formerly believed to be allied to flatbills (*Tolmomyias* and *Rhynchocyclus*), but apparently belongs instead with *Myiarchus* and relatives, based on cranial, syringeal and nesting characters; molecular data still lacking. Present species formerly placed in genus *Rhynchocyclus*. Monotypic.
Distribution. Entire Amazon-Orinoco Basin, including SE Colombia, S & E Venezuela (N to NE Monagas), the Guianas, NE Ecuador, E Peru, N Bolivia, and Amazonian Brazil.



Descriptive notes. 15-16 cm; 17-22·5 g. Brown eye, flat black bill with basal third of lower mandible whitish, grey legs. Plumage is dark olive above; narrow whitish to yellowish supraloral, eyering and faint postocular; dusky wings, two broad wingbars and edges of flight-feathers bright rufous; tail bright rufous; throat greyish, underparts greyish-olive with indistinct pale yellow streaks, except for pale yellow central belly with olive streaks on sides, rufous undertail-coverts. Sexes alike. Voice. Song a soft drawn-out mournful whistle, "weeeaaaweeee", sometimes followed by shorter, lower-pitched and more abrupt flute-like "whoooooo" or plaintive drawn-out "wheeeer"; also undulating and slightly rising "püüeeeaaaeeeer". Song given at fairly long intervals throughout day; dawn song in Colombia an alternating mournful "toooo, reer, wheeee-ooh".
Habitat. Usually found in relatively open middle storey and undergrowth of humid *terra firme* or *várzea* lowland forest; in Colombia most common in sandy woodland (e.g. around Mitú), in Surinam also in savanna forest, and in Brazil in wooded *campina* (*campinarana*). To 600 m.
Food and Feeding. Insects, e.g. lepidopterans, hemipterans (including homopteran and heteropteran bugs), coleopterans, dipterans; also fruit. Usually alone or in pairs, rarely in mixed-species flocks, in forest understorey to mid-storey in more open parts of forest. Perches quietly, and almost motionless, for long periods; suddenly sallies forwards or upwards, or briefly flutter-hovers, to glean insects or pluck fruit from foliage or branches; occasional aerial sallies.
Breeding. Nest, eggs and nestlings in Aug in Peru; female with shell-less egg in oviduct in Oct in Surinam. Builds nest with ample material inside hole or cavity, e.g. inside a broken-off, half-rotten stump 40 cm high, 15 cm deep and 11 cm wide, cavity filled entirely with slender twigs covered by silky milkweed-like material. Clutch 3 eggs; chicks fed by both parents. No further information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Rare to locally fairly common. Has relatively large range within which much of its habitat is in reasonably good condition. Occurs in many national parks and other protected areas, e.g. Tinigua National Park, in Colombia, Caño Colorado (Monagas), in Venezuela, Kapawi and Sacha Lodges, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, several national parks and other reserves in Bolivia, and Jaú National Park, in Brazil.
Bibliography. Allen (1995), Bangs & Penard (1918), Bates & Parker (1998), Boesman (1995), Borges *et al.* (2001), Cadena *et al.* (2000), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Dubs (1992), Fitzpatrick (1980c, 1985a), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hennessey, Herzog, Kessler & Robinson (2003), Hilty (2003), Hilty & Brown (1986), Lanyon (1988a), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Parker (1984), Parker *et al.* (1994), Peres & Whittaker (1991), Remsen & Parker (1995), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thiollay & Jullien (1998), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer (1937a).

399. Dusky-tailed Flatbill

Ramphotrigon fuscicauda

French: Tyran à queue sombre **Spanish**: Picoplano Colioscuro
German: Dunkelschwanz-Breitschnabeltyrann

Taxonomy. *Ramphotrigon fuscicauda* Chapman, 1925, lower River Suno, E Ecuador.
Present genus formerly believed to be allied to flatbills (*Tolmomyias* and *Rhynchocyclus*), but apparently belongs instead with *Myiarchus* and relatives, based on cranial, syringeal and nesting characters; molecular data still lacking. Present species formerly placed in genus *Rhynchocyclus*. Monotypic.
Distribution. S Colombia (SW Putumayo), NE Ecuador (W Napo), C & E Peru (Junín and Ucayali S to Madre de Dios, Cuzco and Puno), N Bolivia and W & WC Brazil (Acre, Rondônia, Pará, Mato Grosso).

Descriptive notes. 15·5-16·5 cm; 16·5-21·5 g. Brown eye, flat black bill with pale base to lower mandible, grey legs. Plumage is brownish-olive above, crown darker, with narrow broken whitish eyering and supraloral; dusky wings and tail, two wingbars and flight-feather edgings cinnamon, tail feathers edged cinnamon-rufous; dark olive with coarse yellow streaks below, yellow central belly. Differs from *R. megacephalum* in larger size, darker plumage, yellower belly. Sexes alike. Voice. Call a drawn-out, descending "peeyooo-wheé" with distinct upward inflection at end; song a mellow mournful "peeeeu, tr'r'r, treey-treey-treey-treey", volume decreasing at end. Also a lazy "peeeeow-whooów", repeated several times.
Habitat. Dense and tangled undergrowth, e.g. near ravines or forest edges, and locally where there are *Guadua* bamboo thickets, in *terra firme*, *várzea* floodplain and swamp-forest, and secondary forest and edge; old overgrown marshes. To 900 m.
Food and Feeding. Insectivore. Usually alone or in pairs, rarely in mixed-species flocks. Perches quietly, and almost motionless, for long periods; uses short forward or upward sallies to hover-glean prey from foliage or branches in relatively dense forest understorey to mid-storey, often near light gaps. Of 23 foraging manoeuvres, most (65%) were upward strike, followed by downward strike (17%) and upward hover-glean (13%).
Breeding. Nest and eggs in Oct in Peru. Builds nest inside hole or cavity; e.g. cavity 0·5 m high inside broken-off, half-rotten limb of fallen tree trunk, filled entirely with mammalian hairs. Clutch 2 eggs. No further information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Very rare to locally uncommon, has fragmented distribution. Occurs in Archidona Natural Reserve, in Ecuador, Manu National Park and Biosphere

On following pages: 400. Rufous-tailed Attila (*Attila phoenicurus*); 401. Cinnamon Attila (*Attila cinnamomeus*); 402. Ochraceous Attila (*Attila torridus*); 403. Genus *ATTILA* Lesson, 1830

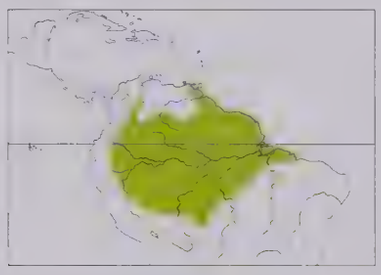
400. **Rufous-tailed Attila**

Attila phoenicurus

French: Attila à queue rousse **German**: Graukopf-Attilatyrann **Spanish**: Atila Cabecigrís
Other common names: Grey-headed Attila

Taxonomy. *Attila phoenicurus* Pelzeln, 1868, Mato Dentro, São Paulo, Brazil.
Formerly placed in a monotypic genus, *Pseudattila*. Monotypic.
Distribution. Breeds in SE Brazil (Rio de Janeiro S to Rio Grande do Sul), probably also in NE Argentina (Misiones) and E Paraguay; migrants widely scattered in Paraguay, E Bolivia, C Brazil and N to S Venezuela during austral winter.



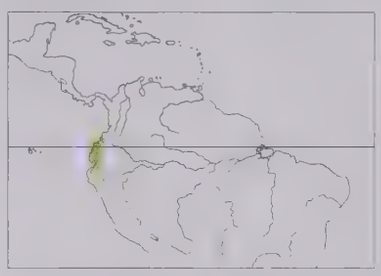
Descriptive notes. 17·6-18 cm; 32·3-34·5 g. Dark eye, dark brown to blackish bill shorter and rounder than in other attilas, usually with small white area at base at lower mandible. Dark grey head and nape contrast with deep rufous upperparts, slightly paler uppertail-coverts and tail; blackish primaries; cinnamon-rufous below, small whitish area on chin, broad but indistinct deep rufous breastband. Differs from *A. citriniventris* in rufous throat, more contrast between grey head and brownish back, darker rump. Sexes alike. Voice. Far-carrying and loud song "bee-bi, béé-bit" whistle, persistently repeated; also sonorous mewing "ew-éé-eh".
Habitat. Humid and mature secondary forest and edge, at least in some areas in *Araucaria*-dominated forest; also in scrub. To 1500 m.
Food and Feeding. Feeds from understorey up to canopy.
Breeding. No information.
Movements. Migrates during austral winter in NW direction into C & N South America; once observed as far N as S Venezuela.
Status and Conservation. Not globally threatened. Rare to locally common; perhaps often overlooked. Limits of breeding range imperfectly known. Particularly numerous in the Serro do Mar (São Paulo), e.g. at Fazenda Intervales, but rare at Saibadela Research Station in Intervales State Park. Occurs also in Fazenda Vale da Revolta (near Teresópolis and Macaé de Cima), Nova Friburgo, and in Aparados da Serra and Itatiaia National Parks. Has been recorded in Noel Kempff Mercado National Park, in Bolivia, and Ybycuí National Park, in Paraguay, but these records are perhaps of austral migrants.
Bibliography. Aleixo & Galetti (1997), dos Anjos *et al.* (1997), Bates & Parker (1998), Bauer & Pacheco (2000), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez (1994), Dubs (1992), Forrester (1993), Friedmann (1948), Hayes (1995), Hilty (2003), Joseph (1996), Mazar Barnett & Kirwan (1998c), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Narosky & Salvador (1998), Pacheco & Parrini (1997), Parker & Goerck (1997), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996).

401. **Cinnamon Attila**

Attila cinnamomeus

French: Attila cannelle **German**: Zimtattilatyrann **Spanish**: Atila Canelo

Taxonomy. [*Muscicapa*] *cinnamomea* J. F. Gmelin, 1789, Cayenne.
Has been considered conspecific with *A. torridus*. Monotypic.
Distribution. Entire Amazon-Orinoco Basin, including E Colombia, W, S & E Venezuela (N to SE Sucre), the Guianas, E Ecuador, E Peru, N Bolivia and Amazonian Brazil.



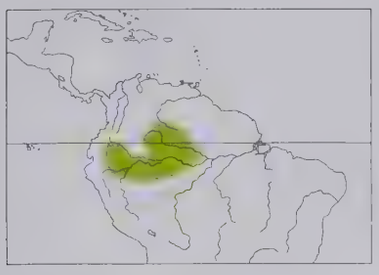
Descriptive notes. 19·5-20·3 cm; 28-45 g. Reddish-brown eyes, black bill, grey legs. Plumage is deep rufous above, no obvious contrast on rump; blackish primaries and dusky wing-coverts with broad rufous edges; cinnamon-rufous below, yellower on belly. Tail longer than that of congeners. Sexes alike. Voice. Call a loud ringing hawk-like whistle, "pü-puéééeeeear", rising and then descending and fading, often persistently repeated; also "whoo-whoo-wheeeyeér", more typical of genus. Song a loud ascending whistle "weary weary weary weer-ry", also slow, reedy series of 3 or more ascending "wheer" whistles, usually repeated persistently.
Habitat. Usually in wet places and near water, e.g. *várzea*, *igapó* and other swampy forests and edge, especially between sand ridges, around old lakes and flooded oxbows, along sluggish streams and on river islands; also wet plantations (e.g. coffee), and swampy palm groves and mangroves in river deltas. To 500 m.
Food and Feeding. Diet consists of larger arthropods, e.g. orthopterans, hemipterans (including homopterans), and also small amphibians; also takes fruit (e.g. *Guarea guara*). Feeds alone or in pairs, rarely in mixed-species flocks, often in the open and at forest edge, and mostly in forest mid-storey; also regularly lower and higher. Perches quietly, and almost motionless or hopping sluggishly, before suddenly sallying short distances or fluttering in order to glean items from foliage and branches.
Breeding. Eggs in Apr-May; nest-building also observed in Sept. Nest built by only one member of pair (Surinam), an open, shallow cup made of small dead sticks, lined with rootlets, placed in crevice in tree trunk or between trunk and bromeliads. Clutch 2-3 eggs. No further information available.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally common. Common in Jaú National Park, in Brazil. Occurs in many other national parks and other protected areas throughout its range, e.g. Caño Colorado (Monagas) and Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Tinigua National Park, in Colombia, Tambopata-Candamo Reserved Zone, in Peru, Beni Biosphere Reserve and Madidi and Noel Kempff Mercado National Parks, in Bolivia, and Rio Cristalino Forest Reserve and Tapajós National Park, in Brazil. Much of its habitat within its relatively large range remains reasonably undisturbed.
Bibliography. Bates & Parker (1998), Boesman (1995), Borges *et al.* (2001), Brace *et al.* (1997), Cadena *et al.* (2000), Cohn-Haft *et al.* (1997), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Parker *et al.* (1994), Peres & Whittaker (1991), Pinto (1948), Remsen & Parker (1995), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1968, 1969), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Zimmer (1936a).

402. **Ochraceous Attila**

Attila torridus

French: Attila ocré **German**: Ockerattilatyrann **Spanish**: Atila Ocre

Taxonomy. *Attila torridus* P. L. Sclater, 1860, Babahoyo, Los Ríos, Ecuador.
Has been considered conspecific with *A. cinnamomeus*. Monotypic.
Distribution. SW Colombia (SW Nariño), W Ecuador and NW Peru (Tumbes).



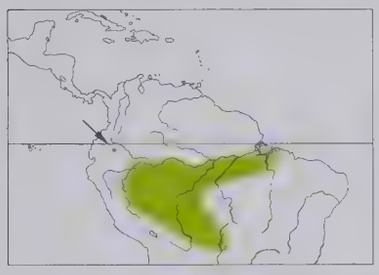
Descriptive notes. 20-22 cm; 46 g. Reddish-brown eyes, dusky bill, grey legs. Paler and yellower version of *A. cinnamomeus*. Has cinnamon-ochraceous head and upperparts; yellowish rump and base of tail; blackish primaries, two distinctive wingbars formed by dusky wing-coverts with broad ochraceous edges; yellowish ochraceous below, yellowest on belly. Sexes alike. Voice. Call a loud, clear, downslurred "whoeeeer" whistle, similar to call of Black Hawk-eagle (*Spizaetus tyrannus*), sometimes extended to "whoeeeer, wheéu, whit-whit"; also sharp "wheek" or "keek" call. Song a rising series of whistles, "wuuu-wuuu-weee-weee-weeé-weeé-wuyeép", in cadence similar to song of *A. cinnamomeus*.
Habitat. Humid and semi-humid forest and edge, second growth and adjacent clearings and plantations; to 1000 m, occasionally to 2400 m.
Food and Feeding. Arthropods (e.g. spiders) and fruit. Feeds alone or in pairs in forest mid-storey to canopy. Perches quietly and almost motionless, before suddenly sallying short distances or fluttering to glean items from foliage and branches.
Breeding. No information. Presumably breeds during wet season (Jan-Mar).
Movements. Probably sedentary; some authors have suggested the occurrence of seasonal movements, but the nature of these remains unclear.
Status and Conservation. VULNERABLE. Rare to locally uncommon. Known from c. 30 sites in W Ecuador and NW Peru; one 1958 record from SW Colombia. Global population of several thousand individuals; seriously declining and becoming increasingly fragmented in its relatively small range of c. 5000 km² owing to continuing deforestation. Below 900 m, only 4·4% of original forest cover remains in W Ecuador, with most of this destroyed since c. 1960. High levels of habitat loss are continuing, at least in unprotected areas, in both Ecuador and Peru, and all remaining lowland forest could soon be lost if effective action is not taken. In higher parts of the species' range, rates of habitat destruction have not been so great, but degradation by livestock grazing, logging and land conversion for agriculture and plantations continue. Even some protected areas adversely affected by grazing, illegal settling and deforestation. The species is somewhat tolerant of disturbance, as it is found in patchy forest fragments; nevertheless, strongholds are in reserves such as, in Ecuador, Machalilla National Park, where it is fairly common, Jauneche Biological Research Station, Río Palenque Science Centre, Loma Alta Ecological Reserve, and Tinalandia Private Reserve, and, in Peru, Northwest Peru Biosphere Reserve. Historical specimens originate from the area now protected as Cotacachi-Cayapas Ecological Reserve, and a concentration of known localities exists at Alamor and on W slope of Cordillera de Celica (both in Loja); reserves should be established here, as continued deforestation had left few forest patches greater than 50 ha ten years ago. Rare at Caberecas de Bilsa, in Esmeraldas, and at Manta Real (designated for protection), in Cañar.
Bibliography. Becker & López (1997), Begazo *et al.* (2001), Best & Clarke (1991), Best & Kessler (1995), Best *et al.* (1993), Clements & Shany (2001), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cracraft (1985), Dodson & Gentry (1991), Hilty & Brown (1986), Meyer de Schauensee (1982), Negret (2001), Pacheco (2002d), Parker & Carr (1992), Parker *et al.* (1995), Renjifo & López (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Walker (2002), Wege & Long (1995), Williams & Tobias (1994).

403. **Citron-bellied Attila**

Attila citriniventris

French: Attila à ventre jaune **German**: Gelbbauch-Attilatyrann **Spanish**: Atila Citrino

Taxonomy. *Attila citriniventris* P. L. Sclater, 1859, River Ucayali, Peru.
Monotypic.
Distribution. E Colombia (E Vaupés, E Guainía, E Amazonas), S Venezuela (C & S Amazonas), E Ecuador, NE Peru and NW Amazonian Brazil.
Descriptive notes. 18-18·5 cm; 30-38 g. Dark reddish-brown eyes, greyish upper mandible, pale horn to pinkish lower mandible with grey tip, grey legs. Dark grey of head and nape becomes rufous-brown on upperparts (including relatively short tail), except for paler cinnamon-rufous rump; dusky wings without wingbars; throat greyish-white, underparts bright ochraceous, faint dusky



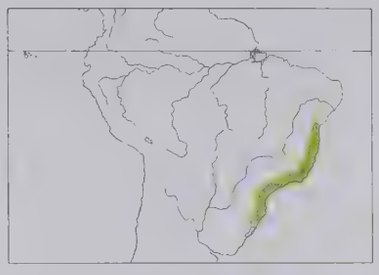
streaking on lower throat and breast, yellower on belly. Differs from *A. phoenicurus* in paler grey head, paler rump, whiter throat. Sexes alike. Voice. Song a series of c. 4-6 loud, rapid and slightly rising "whee" whistles followed by lower-pitched "wu", also a flat-pitched "whee-whee-whee-whee-whee", often persistently repeated. Response to playback lengthens song to 10 or more notes.
Habitat. Humid *terra firme* forest and edge; to 500 m.
Food and Feeding. Larger arthropods, also fruit. Usually alone, sometimes in mixed-species flocks, and at any height, but mostly in forest mid-storey and canopy. Perches quietly, before suddenly sallying short distances or fluttering to glean items from foliage and branches.
Breeding. No information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Rare to locally uncommon; perhaps often overlooked. Fairly common around Mitú (E Vaupés), in Colombia, and occurs in Amacayacu National Park, in Colombia, Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, and Jaú National Park, in Brazil.
Bibliography. Borges *et al.* (2001), Cracraft (1985), Forrester (1993), Friedmann (1948), Hilty (2003), Meyer de Schauensee (1982), Pearman (1994a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1969), Sick (1993, 1997), Stotz *et al.* (1996), Tostain (1980), Willard *et al.* (1991).

404. **Dull-capped Attila**

Attila bolivianus

French: Attila à calotte grise **German**: Weißaugen-Attilatyrann **Spanish**: Atila Ojiblanco
Other common names: White-eyed/Rufous/White-winged Attila

Taxonomy. *Attila bolivianus* Lafresnaye, 1848, Guarayos, Santa Cruz, Bolivia.
Two subspecies recognized.
Subspecies and Distribution.
A. b. nattereri Hellmayr, 1902 - SE Colombia (SE Amazonas), NE Ecuador (Sucumbíos, Napo), E Peru and C Brazil (both banks of lower Amazon E from left bank of lower R Madeira).
A. b. bolivianus Lafresnaye, 1848 - SW Brazil (SW Amazonas, SW Mato Grosso) and N Bolivia.



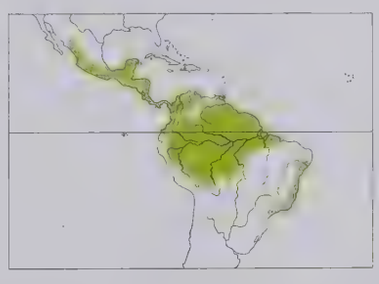
Descriptive notes. 19-22 cm; 40-45 g. Distinctive pale yellowish-white eyes, horn-coloured bill mostly pinkish-tinged below, blue-grey legs. Has rufous-brown head and upperparts, greyer on crown, bright cinnamon-rufous rump and tail; mainly blackish greater wing-coverts and primaries; cinnamon-rufous below, paler on belly, faint greyish chin. Differs from other Amazonian attilas (especially rufous morph of *A. spadiceus*) in larger size, longer bill and tail, and uniform cinnamon underparts. Sexes alike. Race *nattereri* is distinctly darker overall than nominate, with crown more sepia. Voice. Main song a leisurely ascending series of 4-8 "whéep" whistles followed by weaker and lower-pitched "wheeuu", often alternated with several "wée-per". Loud, sharp, rapid staccato rattle, "tu-tu-tu-tu-tu", when disturbed.
Habitat. *Várzea* and other swampy forests and edge, often along rivers or on river islands; also in gallery forest in the pantanal of Mato Grosso (Brazil). To 300 m.
Food and Feeding. Larger arthropods, also fruit. Feeds alone or in pairs, sometimes in mixed-species flocks, in open forest understorey and mid-storey. Perches quietly, almost motionless, before suddenly sallying short distances or fluttering and hovering to glean items from foliage and branches.
Breeding. Gonads enlarged in Sept, in SE Peru. Nest found in Jun in Colombia, a rusty-coloured mossy cup made from rootlets, moss and plant fibres, placed at base of epiphyte on trunk 1·3 m above water in *várzea* forest. Clutch 2 eggs. No other information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Given that much of its habitat within its relatively large range remains more or less undisturbed, it is not at any risk. Occurs in many national parks and other protected areas, e.g. Sacha and Yarina Lodges, in Ecuador, Explornapo Lodge (Loreto), Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Beni and Pilón Lajas Biosphere Reserves and Madidi and Noel Kempff Mercado National Parks, all in Bolivia, and Mamirauá Reserve (Amazonas), in Brazil.
Bibliography. Allen (1995), Bates & Parker (1998), Brace *et al.* (1997), Dubs (1992), Fitzpatrick (1980c, 1985a), Forrester (1993), Hennessey, Herzog, Kessler & Robinson (2003), Hilty & Brown (1986), Howell (2002), Karr *et al.* (1990), Kirwan (1996), Meyer de Schauensee (1982), Naumburg (1930), Pacheco (1995), Parker *et al.* (1994), Remsen & Parker (1995), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schönwetter & Meise (1969), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984), Traylor & Fitzpatrick (1982), Willis & Oniki (1990).

405. **Grey-hooded Attila**

Attila rufus

French: Attila à tête grise **German**: Streifenkehl-Attilatyrann **Spanish**: Atila Encapuchado
Other common names: Grey-throated Attila

Taxonomy. *Tyrannus rufus* Vieillot, 1819, Cayenne; error = Rio de Janeiro, Brazil.
Two subspecies recognized.
Subspecies and Distribution.
A. r. hellmayri Pinto, 1935 - C & S Bahia, in E Brazil.
A. r. rufus (Vieillot, 1819) - SE Brazil, from E Minas Gerais and Espírito Santo S to NE Rio Grande do Sul.
Descriptive notes. 20-21 cm; 36·5-51·5 g. Dark eyes, rather long bill with whitish to greyish lower mandible, grey legs. Nominate race has grey head and nape contrasting with deep rufous back, paler cinnamon-rufous rump and tail; blackish primaries; grey throat with white streaks, contrasting with rufous breast and paler yellowish belly. Differs from *A. phoenicurus* in larger size, longer bill, grey throat faintly streaked whitish. Sexes alike. Juvenile has black bill. Race *hellmayri* has mostly rufous throat, whitish chin. Voice. Call an "éé-ew" whistle. Far-carrying and melodious song a series of 6-13 slowly delivered "wee" or "ewéé" whistles, pitch and volume gradually increasing before lowering on last whistle; also softer shorter "wee, tee-tee-pu" whistle that sometimes alternates with previous song. Warning a hard shrieking "tserétek, tsek".



Habitat. Humid lowland and montane forest and edge, also scrub; to 1500 m.
Food and Feeding. Larger arthropods, e.g. ants (Hymenoptera), butterflies (Lepidoptera); tree frogs; also fruit. Feeds alone or in pairs, sometimes in mixed-species flocks, from ground (where relatively frequently found) up to canopy. Perches quietly, and almost motionless, before suddenly sallying short distances or fluttering and hovering to glean items from foliage and branches. Also reported as hammering on rotten wood.
Breeding. Little information. Builds bulky nest in tree trunk or tree-fern, also in tunnel-like cavity inside embankment.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to fairly common; apparently more common at lower elevations. Fairly common at Saibadela Research Station in Intervales State Park; occurs also in Mata dos Godoy and Rio Doce State Parks, Augusto Ruschi and Sooretama Biological Reserves, and Itatiaia and Tijuca National Parks.
Bibliography. Aleixo & Galetti (1997), dos Anjos *et al.* (1997), Bauer & Pacheco (2000), Cracraft (1985), Develey (2004), Forrester (1993), Guix *et al.* (1992), Meyer de Schauensee (1982), Parker & Goerck (1997), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1969), Sick (1993, 1997), Simon (2000), Skutch (1971, 1981), Stotz *et al.* (1996), Venturini *et al.* (2001).

406. **Bright-rumped Attila**

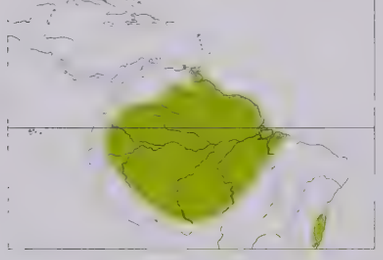
Attila spadiceus

French: Attila à croupion jaune **German**: Gelbbürzel-Attilatyrann **Spanish**: Atila Polimorfo
Other common names: Polymorphic/Streaked Attila

Taxonomy. [*Muscicapa*] *spadicea* J. F. Gmelin, 1789, Cayenne.
Races differ vocally, with dawn songs falling into Middle and South American groups, suggesting that more than one species may be involved; further study required. Twelve subspecies recognized.
Subspecies and Distribution.
A. s. pacificus Hellmayr, 1929 - coastal W Mexico, from Sinaloa S to W Oaxaca.
A. s. flammulatus Lafresnaye, 1848 - SE Mexico (Veracruz and E Oaxaca E to S Quintana Roo), Guatemala, Belize and NC Honduras.
A. s. gaumeri Salvin & Godman, 1891 - N Yucatán Peninsula (SE Mexico), including islands of Holbox, Meco and Mujeres.
A. s. cozumelae Ridgway, 1885 - Cozumel I, off NE Quintana Roo.
A. s. salvadorensis Dickey & van Rossem, 1929 - El Salvador S to NW Nicaragua.
A. s. citreopygus (Bonaparte, 1854) - SE Honduras and Nicaragua S to W Panama.
A. s. sclateri Lawrence, 1862 - E Panama and adjacent NW Colombia.
A. s. parvirostris J. A. Allen, 1900 - N Colombia (Santa Marta region) and NW Venezuela (Maracaibo Basin).
A. s. caniceps Todd, 1917 - middle Magdalena and lower Sinú Valleys, in N Colombia.
A. s. parambae Hartert, 1900 - W Colombia S to NW Ecuador (S to Manabí and Pichincha).
A. s. spadiceus (J. F. Gmelin, 1789) - W & N Venezuela (Táchira, W Apure, SE Lara, and Falcón E to Aragua), Trinidad, and entire Amazon-Orinoco Basin from SE Colombia NE to the Guianas and S to E Ecuador, E Peru, N Bolivia and S Amazonian Brazil.
A. s. uropygiatus (Wied, 1831) - coastal E Brazil (Alagoas, S Bahia, Espírito Santo, Rio de Janeiro).

Descriptive notes. 17-21·5 cm; 31·4-44 g. Polymorphic, but always with two distinctive wingbars, yellow rump, and breast streaking; yellow to orangey-hazel to reddish-brown eyes, pinkish lower mandible with dusky base and tip, blue-grey legs. Nominate race has short yellowish supercilium; head and upperparts dark olive, rump bright yellow, tail dull rufous; dusky wings, two rufous-tinged wingbars; olive throat and breast with narrow yellow streaks, whitish belly, pale yellow crissum. Rufous morph has olive parts of plumage replaced with rufous, rump more orange-yellow, belly tinged cinnamon, no supercilium; grey morph substitutes olive with grey (except for olive back), has paler and greyer wingbars, no supercilium. Sexes alike, female with paler eyes than male. Juvenile has brown eyes (Costa Rica). Middle American races differ in having more cinnamon to brownish upperparts (with ochraceous rump in most N populations), greyish supercilium, more whitish to yellowish underparts with dusky streaking; *pacificus* rather pale, with bright cinnamon upperparts; *flammulatus* dusky rufous above, whitish central belly; *gaumeri* smaller and paler than previous, with proportionately larger bill; *cozumelae* similar to previous but with ochraceous rump, and deeper cinnamon-buff underwing-coverts; *salvadorensis* like *flammulatus* but very slightly paler; *citreopygus* variable, like *flammulatus* but smaller, with head more olive; *sclateri* like previous, but olive extends from head to back; *caniceps* like previous, but with greyer crown, and less yellow tinge to throat and breast; *parvirostris* has heavier bill, rufous-brown back, duller crown, and throat and breast strongly washed orange, also has rufous morph; *parambae* like *sclateri* but generally duller and darker; *uropygiatus* very similar to nominate, but larger with stronger, heavier bill. Voice. Both sexes sing. Dawn songs differ between Middle and South American populations: a series of emphatic and ascending "whée-dip" whistles (c. 5-7, but rather variable), usually followed by distinctly downslurred "whew" (South America) or a "whew-whit" (Middle America), this whistle often alternated with several "weed we-to" whistles, also increasing in pitch and volume and sliding off at end; these characteristic 2-note and 3-note phrases occur with numerous variations. Day songs differ from dawn songs, but are similar across entire range. Numerous

other vocalizations, e.g. loud and sharp "pi-dik" or "ki-di-dik", quiet "prrr" or "pi-rrrr" growls, also loud, sharp, rapid staccato "di-di-di-di" rattle when disturbed, and sharp harsh notes when foraging; a long series of low soft notes by incubating female ("nest song").
Habitat. Humid lowland forest (e.g. *terra firme*), swampy and foothill forest and edge, also second growth, clearings, plantations and gardens with tall trees, semi-arid deciduous forest and edge, scrubby woodland and bushy patches in savanna; occasionally in large gallery forests in *llanos*, and even pine (*Pinus*) forests. Usually below 1500 m, occasionally to 2100 m.
Food and Feeding. Mainly large arthropods and small vertebrates, especially frogs and lizards (e.g. *Anolis limifrons*, *Lygosoma cherriei*); also small fruits and arillate seeds (e.g. *Alchornea costaricensis*, *Dipterodendron elegans*, *Davilla kunthii*). Analysis of 13 prey items taken from stomachs in SE Peru included: lizards (32%), Homoptera (cicadas 26%, planthoppers 8%), Coleoptera (16%), Lepidoptera (8%), and Arachnida (spiders 8%). Forages alone or in pairs, rarely in mixed-species flocks, at any height, even regularly on ground, but usually in from forest midstorey up to canopy. Perches quietly, and almost motionless, before suddenly sallying short distances or fluttering and hovering to glean food items from foliage and branches or from the ground.
Breeding. Mainly Mar-Jul in Central America, from Apr in Belize; nests from Mar (pair in breeding condition in Feb) in Colombia, and in Mar-Apr in Trinidad; eggs and nestlings in Sept in Surinam. Nest, built by female, an open, shallow and bulky cup, length and depth 8·3-8·5 × 3·8-4 cm, made of moss, small dead sticks, fine leaves, green fern fronds and rootlets, placed low down (usually not above 2 m) in crevice or cavity in tree trunk, between trunk and epiphytes or between butresses or stump sprouts, or in branch fork, bromeliad or mossy rock outcrop, or in roadside or streamside bank, often well outside forest. Clutch 2-4 eggs; incubation by female, period c. 18-19 days; chicks fed by both parents, nestling period c. 18 days.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Has relatively large range, within which extensive areas of suitable habitat remain in reasonably good condition. Conservation status of isolated E Brazilian race (*uropygiatus*) may merit investigation. Occurs in numerous national parks and other protected areas throughout most of its range.
Bibliography. Anon. (1998a), Bates & Parker (1998), Begazo (1995), Binford (1989), Borges *et al.* (2001), Cadena *et al.* (2000), Clements & Shany (2001), Cooper (1997), Cracraft (1985), Dickey & van Rossem (1938), England (2000), ffrench (1991), Fitzpatrick (1985a), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hennessey, Herzog, Kessler & Robinson (2003), Hilty (1997, 2003), Hilty & Brown (1986), Howell & Webb (1995a), Lee Jones (2004), Leger & Mountjoy (2003), Monroe (1968), Munn (1985), Olson (1997), Oren & Parker (1997), Parker (1993a), Parker & Carr (1992), Parker & Goerck (1997), Parker *et al.* (1994), Pérez & Villeda (2000), Remsen & Parker (1995), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Robinson & Terborgh (1997), Salaman (1994), Schönwetter & Meise (1969, 1977), Sick (1993, 1997), Skutch (1971, 1981, 1985), Silveira *et al.* (2003), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Temple (2002), Terborgh *et al.* (1984), Tostain *et al.* (1992), Traylor & Fitzpatrick (1982), Wetmore (1972), White (2002), Willis (1980).



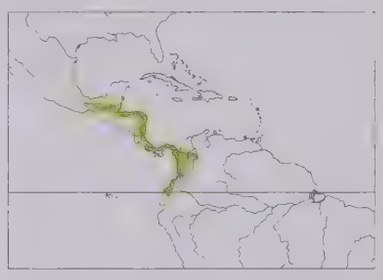
Genus *LANIOCERA* Lesson, 1840

407. Cinereous Mourner

Laniocera hypopyrra

French: Aulia cendré **German**: Grauer Tropfenflügeltyrann **Spanish**: Plañidera Cenicienta

Taxonomy. *Ampelis hypopyrra* Vieillot, 1817, La Guyane = Cayenne.
Genus often placed in Cotingidae, and possibly better treated in that family. Scientific name has often been misspelled as "*hypopyrrha*". Forms a superspecies with *L. rufescens*. Monotypic.
Distribution. Entire Amazon-Orinoco Basin, including SE Colombia, S & E Venezuela (N to SE Sucre), the Guianas, E Ecuador, E Peru, N Bolivia, and Amazonian Brazil; isolated population in SE Bahia and N Espírito Santo, in coastal E Brazil.



Descriptive notes. 20-21 cm; 41-51 g. Dark eyes with narrow orange eyering, dark bill, grey legs; rounded head and bill yielding appearance somewhat like that of a dove (Columbidae) or a thrush (Turdidae). Plumage is mainly grey, slightly paler below; brown-tinged primaries, two rows of large cinnamon spots forming broken wingbars, smaller cinnamon spots on tertials and tail tips; sometimes black-tipped orange spots on breast and crissum, latter rufous-tinged and faintly barred; orange or pale yellow pectoral tufts (often hidden). Sexes alike. Immature has some rufous intermixed with black spots on breast. Voice. Far-carrying, ventriloquial insect-like song a series of 10-15 very high-pitched, thin, drowsy and slurred "tee-o-weeét" whistles, first whistle often longer "cheeeeee-a-wee"; lengthy pauses between songs, but repeated persistently even during heat of day. Also series of 3-4 plaintive "teeéuw" whistles and a repeated "weet-jeh" shriek.
Habitat. Humid *terra firme* and *igapó* flooded forests, especially on sloping terrain or near ravine woodlands; also humid sandy-belt forests and more extensive savanna woodlands, and wooded sand ridges in coastal regions. To 900 m.
Food and Feeding. Arthropods, e.g. lepidopterans, dipterans; also fruit. Usually alone, sometimes in mixed-species flocks, usually in understorey or mid-storey. Perches quietly and almost motionless; uses short sallies or brief flutters and hovers to glean items from foliage or branches.
Breeding. Gonads enlarged Sept-Nov in Peru and Bolivia; nest Sept in SE Peru, bulky cup made of dry leaves, constructed among the branches of an epiphytic fern attached to tree trunk, 1·8 m above the ground, in 4-m tall tree under mature, floodplain forest in relatively open area with little vegetation cover in the understorey and no tall, woody plants within 2 m. Clutch 2 eggs, apparently tended by only a single individual.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Rare to locally fairly common. Fairly common in sandy-belt forest and savanna woodland in SE Colombia, e.g. around Puerto Inírida. Conservation status of small isolated population in E Brazil uncertain. Much of its habitat is in relatively pristine condition within its large range. Found in many national parks and other protected areas, e.g. Caño Colorado (Monagas) and Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Tinigua National Park, in Colombia, Kapawi Lodge, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and several large reserves both in Bolivia and in Brazil.
Bibliography. Bangs & Penard (1918), Bates & Parker (1998), Blake (1962), Boesman (1995), Borges *et al.* (2001), Brace *et al.* (1997), Cadena *et al.* (2000), Cohn-Haft *et al.* (1997), Friedmann (1948), Gilliard (1941), Haffer (1974), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Londoño (2003), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Parker & Goerck (1997), Parker *et al.* (1994), Pinto (1948), Remsen & Parker (1995), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Terborgh *et al.* (1984), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Walther (2002), Willard *et al.* (1991), Zimmer (1930, 1936a).

408. Speckled Mourner

Laniocera rufescens

French: Aulia tacheté **German**: Rötlicher Tropfenflügeltyrann **Spanish**: Plañidera Moteada

Taxonomy. *Lipaugus rufescens* P. L. Sclater, 1858, Cobán, Alta Verapaz, Guatemala.
Genus often placed in Cotingidae, and possibly better treated in that family. Forms a superspecies with *L. hypopyrra*. Three subspecies recognized.
Subspecies and Distribution.
L. r. rufescens (P. L. Sclater, 1858) - SE Mexico S to coastal NW Colombia.
L. r. griseigula Meyer de Schauensee, 1950 - NW Colombia (Córdoba, N Antioquia, Santander).
L. r. tertia Hartert, 1902 - SW Colombia (Cauca, W Nariño) and NW Ecuador (Esmeraldas, Pichincha).

Descriptive notes. 19-21·5 cm; 38·6-56 g. Dark brown eyes with narrow orange eyering, blackish bill with greyish-flesh base of lower mandible, brownish-grey legs. Plumage is mostly rufous-brown, slightly paler and more cinnamon below, usually with faint fine dusky scalloping on breast; pale yellow to orange pectoral tufts (often hidden); dusky wing-coverts, large rufous spots on tips forming two or three faint wingbars. Female usually lacks pectoral tufts. Immature resembles female, but with more prominent markings on wings and underparts, greyish wash on head, lower throat and back, sometimes sparse black breast spots. Race *griseigula* is slightly smaller and darker than nominate, duller cinnamon and rufous-brown, with central foreneck and upper breast grey; *tertia* similar to than nominate, but darker and more chestnut, particularly above. Voice. Ventriloquial and ringing song a series of up to 15 very high-pitched, thin "tlee-yeeí" whistles, given with lengthy pauses between songs, but repeated persistently even during heat of day. Also plaintive, drawn-out, slightly mewing "peeeeeeeu" with abrupt end.
Habitat. Humid and mature second-growth forest and edge, often near swampy places, ravines and streams; to 1000 m.
Food and Feeding. Diet consists of arthropods (e.g. lepidopterans), small lizards, and fruit. Usually forages alone, sometimes in mixed-species flocks, from understorey to subcanopy. Perches quietly, and almost motionless; use short sallies or brief flutters and hovers to glean food items from foliage or branches.
Breeding. No information. Birds in breeding condition in May in Colombia.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Rare to locally fairly common. In Panama, most common in Bocas del Toro. Probably locally extinct in areas where deforestation has been intense (e.g. in lowland forest in Chiriquí, in Panama). Considered "near-threatened" in Ecuador because of its rarity and strict dependence on large undisturbed forest tracts. Occurs in Columbia River Forest Reserve and Río Bravo Conservation and Management Area, in Belize, and Río Palenque Science Centre, in Ecuador; possibly present also in Awá Forest Reserve and Cotacachi-Cayapas Ecological Reserve, both in Ecuador.

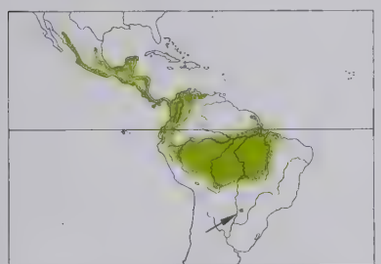
Subfamily TITYRINAE



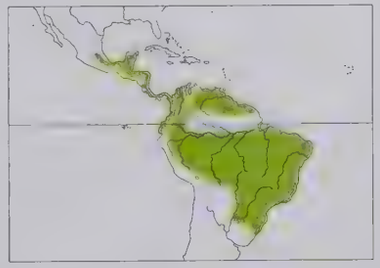
Genus *TITYRA* Vieillot, 1816

409. Masked Tityra

Tityra semifasciata

French: Tityre masqué **German**: Weißnackentityra **Spanish**: Titira Enmascarado

Taxonomy. *Pachyrhynchus semifasciatus* Spix, 1825, Pará, Brazil.
Genus formerly included with *Pachyramphus* in the Cotingidae, but transferred to the present family on the grounds of several shared, derived similarities of the skull and syrinx. Because of their similarity to cotingids in respect of many other features, some authors prefer to treat both genera as representing a separate family (Tityridae) or to leave them in Cotingidae. Phylogenetic affinity of genus and of this species currently unknown; molecular investigation needed. Nominate race and *fortis* intergrade in W Amazonia, such that distributional limit of each not entirely clear. Race *hannumi* often merged with *griseiceps*. Nine subspecies currently recognized.
Subspecies and Distribution.
T. s. hannumi van Rossem & Hachisuka, 1937 - NW Mexico (SE Sonora, SW Chiuahua, NE Sinaloa).
T. s. griseiceps Ridgway, 1888 - W Mexico (coast region from N/C Sinaloa and W Durango S to S Oaxaca).
T. s. personata Jardine & Selby, 1827 - E Mexico (SW Tamaulipas, SE San Luis Potosí, N Distrito Federal and N Puebla E to Yucatán), N & S Guatemala, Belize, W & C Honduras, El Salvador and NC Nicaragua.
T. s. deses Bangs, 1915 - SE Mexico (Yucatán).
T. s. costaricensis Ridgway, 1906 - SE Honduras, Nicaragua (except NC area), Costa Rica and W & C Panama (including Coiba I and Cébaco I).
T. s. columbiana Ridgway, 1906 - E Panama, N & W Colombia (Bolívar and Magdalena S to Chocó, N Antioquia and WC Santander) and NW & N Venezuela (Sierra de Perijá, Andes, and coastal range from Yaracuy E to Miranda).
T. s. nigriceps J. A. Allen, 1888 - extreme SW Colombia (Nariño) and NW Ecuador (Esmeraldas, Manabí, W Pichincha, W Guayas, Los Ríos, NW Azuay).
T. s. fortis Berlepsch & Stolzmann, 1896 - E Colombia (E slope of E Andes), E Ecuador (along base of E slope), E Peru (Loreto and San Martín S to E Ayachucho and Puno), N & E Bolivia (La Paz, Cochabamba and Beni E to Santa Cruz) and WC Brazil (Mato Grosso).
T. s. semifasciata (Spix, 1825) - French Guiana, Brazil (primarily S of Amazon in C & S Amazonas E to Pará, Amapá and N Maranhão, S to Acre, Rondônia, S Mato Grosso and N Goiás) and NE Paraguay (Canindeyú).



Descriptive notes. 20-24 cm; 77-88 g. Male has black mask with bare rosy-red facial skin and ocular area, narrowly surrounded by black feathers in area of forecrown, upper chin and face; rest of head and upperparts pale greyish-white, heavily tinged pearly grey; wings mostly black, greyish-white tertials; primary P9 very short, outermost primary normal; tail greyish-white, broad black subterminal band; throat and underparts more or less whitish; iris reddish-brown to brick-red; bill slightly hooked, rosy red, black terminally; legs blackish. Female has head more smoky or dusky brownish, no black mask, some brown smudging and streaking on dull and darker grey back, dingy and more pale greyish underparts. Juvenile resembles adult female, but has narrower whitish tips on rectrices, paler upperparts washed with brown; immature plumage acquired quickly, also like female but paler and greyer upperparts; adult plumage also attained quickly (Mar-Aug in Mexico). Races vary somewhat, but not well defined: considerable and apparantly irregular variation in nominate race towards *fortis*, with its longer and heavier bill; male *costaricensis* is nearly identical to nominate, but upperparts including median and lesser wing-coverts, tertials and base of tail more pale grey, female darker than nominate, especially on head; male *nigriceps* whiter than nominate, has slightly more black on face, sometimes black spotting on hindcrown, and broader black subterminal band on tail; male *griseiceps* is greyer above, female has pale grey head and upperparts, back washed grey-brown, paler and greyer on inner wing-coverts and tertials; *personata* fairly uniform grey above and below, with greyish-brown head and upperparts, darker on head; *deses* similar to nominate, but paler all over, especially on underparts; *columbiana* similar to nominate, but with less white at base of outer rectrices, female has browner upperparts. Voice. Typical call a distinctive buzzy, nasal, staccato, and croaking or clicking "zzzu rrk" or "zzr zzzrt" and "rr-rr-rrk", etc.; commonly a dry, nasal, and grunting or almost pig-like "querp" or "kuert", sometimes doubled "gurank-gureek" or "reek-reek" and "reek-rack", with second note a bit higher, or a longer and more rhythmic series of similar notes with two pitches, "ghe-rák-gherik"; also quieter "rruk, rruk" or "eg-eg" call, snorted "gaaaa", and variety of dry notes that recall some insect sounds. Male said to create sonorous hissing sound with wings, mostly when slowing in flight immediately before perching.
Habitat. Humid to semi-arid forest canopy and crown of taller trees along forest edges, woodland, palm stands, second growth, relatively open areas from forest clearings to savana with scattered trees, and plantations. Mostly below 1200-1500 m, but recorded up to over 1800 m in Panama (Chiriquí) and Venezuela, up to 2300 m on Pacific slope of Costa Rica, and up to 2500 m in W Mexico (Sinaloa).
Food and Feeding. Mostly frugivorous; some insects, occasionally small lizards. Observed singly, in loose pairs, or in small straggling flocks of 3-4 individuals. Generally perches conspicuously on a bare branch at middle to upper levels; rather antisocial, and often aggressive towards other birds. Consumes much fruit, including figs, arils (*Casearia*, *Trichilia*, *Virola*), and lauraceous fruits, usually by perch-gleaning, sometimes by sally-gleaning; one of many consumers and/or seed-dispersers of *Virola surinamensis* and *V. sebifera* (Myristicaceae) and *Guarea glabra* (Meliaceae) in Panama; also a primary disperser of *Casearia corymbosa* (Flacourtiaceae) in Costa Rica. Also sally-gleans, sometimes fluttering briefly, or perch-gleans large insects from foliage; occasionally pursues insect prey; also hops lethargically and heavily along branches and large limbs, looking for insect prey and fruit.
Breeding. Mar-Jul in Costa Rica, sometimes two broods; in Colombia, birds in breeding condition in Jan-May (in NW) and nest-building and cavity-occupancy behaviour observed Feb-Apr and Aug (Anchicayá Valley). Male, with stooped posture and drooping wings, runs back and forth on horizontal branch, while making croaking sound, in presence of female, which usually actively pursues male; up to 4 individuals displaying together near occupied nest. Nest, so far as is known built mostly by female, in tree cavity or old woodpecker (Picidae) hole at middle to upper levels, generally c. 12-30 m high, rarely as low as 3-4 m, cavity usually partly filled loosely with large quantity of dead leaves, twigs, inflorescences and other plant matter; sometimes nests in same tree as *T. inquisitor*. Clutch 2-3 eggs; incubation by female, eggs apparently covered with nest material when nest left temporarily unattended, period thought to be c. 18-21 days; chicks fed by both sexes, nestling period c. 20-30 days.
Movements. No significant movements known. Vagrant regularly observed in S USA (S Texas) Feb-Mar 1989, following a late-Dec freeze that extended far into Mexico.
Status and Conservation. Not globally threatened. Fairly common to common. Apparently more abundant W of Andes. Much suitable habitat for this remains in relatively pristine condition within its large range. Occurs in many national parks and other protected areas.
Bibliography. Anon. (1998a), Bates & Parker (1998), Binford (1989), Clements and Shany (2001), Cory and Hellmayr (1927), Haffer (1975), Hilty (2003), Hilty & Brown (1986), Hinojosa *et al.* (1998), Howe (1981), Howell & Webb (1995a), Land (1970), Lanyon (1985), Lee Jones (2004), Lowen *et al.* (1997), Lowery & Dalquest (1951), McKitrick (1985), Meyer de Schauensee (1966, 1982), Moermond & Denslow (1985), Monroe (1968), Novaes (1992), Olson (1997), Oren & Parker (1997), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 1994), Ridgway (1907), Robinson (1997), Rowley (1984), Salaman (1994), Schulenberg *et al.* (2001), Sibley & Ahlquist (1985c), Sick (1993, 1997), Skutch (1969), Slud (1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Tostain *et al.* (1992), Traylor (1977), Wetmore (1943, 1972), Willis (1980), Zimmer (1930, 1936b).

410. Black-crowned Tityra

Tityra inquisitor

French: Tityre à tête noire **German**: Schwarzschnabeltityra **Spanish**: Titira Piquinegro
Other common names: White-tailed Tityra ("*T. leucura*")

Taxonomy. *L[anius] Inquisitor*, M. H. K. Lichtenstein, 1823, São Paulo, Brazil.
Genus formerly included with *Pachyramphus* in the Cotingidae, but transferred to the present family on the grounds of several shared, derived similarities of the skull and syrinx. Because of their similarity to cotingids in respect of many other features, some authors prefer to treat both genera as representing a separate family (Tityridae) or to leave them in Cotingidae. Phylogenetic affinity of genus and of this species currently unknown; molecular investigation needed. In the past, was sometimes placed in a separate genus, *Erator*, with nominate race and *erythrogenys* then treated as forming one species, and *pelzelni*, *albitorques* and *buckleyi* as three further species. Form "*leucura*" was also described as a full species, based only on the type specimen (from R Madeira, in Brazil), but description indicates that it represents an abnormal subadult intermediate between *albitorques* and *pelzelni*, ranges of which apparently overlap in the area. A further named race, *selbii*, of S Brazil is considered inseparable from nominate. Although considerable variation exists among some races, exact limits and biological nature of such divergence require closer inspection; *fraserii* and *albitorques* appear to intergrade in Costa Rica. Six subspecies currently recognized.
Subspecies and Distribution.
T. i. fraserii (Kaup, 1852) - E & SE Mexico (extreme SE San Luis Potosí, NE Distrito Federal, NE & E Puebla and S Veracruz E to Yucatán Peninsula, S to N Oaxaca and N Chiapas) and N Guatemala S to C Panama (including islands of Espartal, Brava and Sevilla, off Chiriquí).
T. i. albitorques Du Bus de Gisignies, 1847 - E Panama, N & W Colombia (S to W Valle del Cauca, and Magdalena Valley S to N Huila), W Ecuador (S to Guayas and NW Azuay), N & C Peru (W Loreto, San Martín, Ayacucho), NW Bolivia (Pando, Beni) and NW Brazil (R Juruá and Amazon E to Manaus).
T. i. erythrogenys (Selby, 1826) - E Colombia (E of Andes from Norte de Santander, Arauca and Meta E to R Orinoco), N, C & S Venezuela (S Maracaibo Basin E to Sucre, W slope of Andes S from to Trujillo and E slope S from N Barinas, coastal mountains S to Guárico, also Amazonas and N Bolívar), Surinam, French Guiana and N Brazil (N of lower R Amazon); probably also Guyana.
T. i. buckleyi Salvin & Goodman, 1890 - SE Colombia (W Caquetá and Putumayo E to Amazonas) and E Ecuador (Napo, Pastaza).
T. i. pelzelni Salvin & Goodman, 1890 - N & E Bolivia (La Paz, Cochabamba, Santa Cruz) and WC & NE Brazil (S of Amazon, from left bank of R Madeira E to E Maranhão, S to Mato Grosso).
T. i. inquisitor (M. H. K. Lichtenstein, 1823) - E & SE Brazil (S Piauí and interior Bahia S to N Rio Grande do Sul), E Paraguay (E from near R Paraguay) and NE Argentina (E Formosa, E Chaco, Corrientes).

Descriptive notes. 17-20·5 cm; 40-50 g. Male nominate race has black crown, lores, auriculars and subocular area; upperparts mostly whitish-grey, heavily tinged pearly grey; wings mostly black, tertials greyish-white; primary P9 greatly reduced in length, outermost primary normal; tail entirely black; throat and underparts white; iris dark; upper mandible bluish-grey, lower mandible blackish; legs blackish. Female has buffy forehead, chestnut or rusty side of head, black cap, duller and slightly darker grey back with dusky brownish streaking and coarsely spotted blackish, dingy pale greyish-buff wash on throat and breast. Juvenile (*fraserii*) closely resembles female, but has black and cinnamon or chestnut mottling on crown, white nape with buff and dusky mottling, whitish and grey mottling on upperparts, buff-tinged wing-coverts and tertials mottled dusky, underparts tinged with buff; immature plumage attained quickly, like female, but young male has white forehead, pale grey upperparts, crown sometimes mottled; adult plumage also acquired quickly. Races vary considerably in plumage, also generally larger in S: *fraserii* has white nape and cheek, shading into pale greyish-white on under-

On following page: 411. Black-tailed Tityra (*Tityra cayana*).

parts, darker back, inner webs of primaries white basally (conspicuous patch in flight), female has more brownish (not grey) back and scapulars; *albitorques* is slightly smaller, also has white cheeks (and auriculars), has pale grey back, greyish underparts, and tail mostly white (black reduced to subterminal band c. 20 mm wide usually bordered terminally by white apical margins), female has pure white lower belly and crissum and unspotted brownish-washed back (variable); *erythrogenys* is generally similar to nominate, but smaller, with less white on hindneck, only extreme base of tail white with no white apical margin, female has grey back without brownish suffusion and more or less spotted with black (significant individual variation) and white throat or chest with slight greyish tinge; *buckleyi* has white cheeks and auriculars, predominantly black tail with white only at very extreme base of rectrices (except for an Ecuador specimen which has small but prominent white apical spots on three outer rectrices and more white at base of outer web of penultimate rectrix); *pelzelni* has head pattern like nominate (some specimens from lower Amazon have white streaks on auriculars), tail mostly white (especially birds from lower Amazon) but considerable individual variation in extent of white at base of rectrices and white apical margin (least in Bolivia and Mato Grosso). VOICE. Usually rather quiet. Typical calls a husky grunting or dry guttural, somewhat strident, frog-like and variable "sheh-shehk", "squik" or "zick-zick-zick", and a series of low, weak, and nasal "chet-chut, chaa-cherp" notes, often given as two notes in a series; call also described as an odd-sounding nasal grunting with buzzy quality, "uurnt" or "uurnt-uurnt"; on addition, gives strange thin "corre corre" call.

Habitat. Humid to semi-humid tall forest canopy and mature second growth along borders, clearings with scattered tall trees near continuous forest, river edges, and plantations; also *várzea*. Mostly below 1200 m.

Food and Feeding. Largely frugivorous, but also captures much invertebrate prey, primarily to feed offspring. Observed singly, in pairs, or in small groups. Fairly antisocial, sometimes aggressive towards other birds, and almost never associates with mixed flocks. Generally perches conspicuously on a bare branch at middle to upper levels, but regularly lower, and sometimes for long periods. Scans foliage intently, looking for large insects and caterpillars, which it takes by quick upward strikes to vegetation; occasionally perch-gleans or hover-gleans insects and relatively large fruits.

Breeding. Nestlings in Mar-Jun in Costa Rica; males in breeding condition in May (S César) and Jul (Norte de Santander) in Colombia; breeding behaviour in May-Aug in Venezuela (SW Guárico); nest in Dec in Brazil (Rio Grande do Sul); nest in Oct and one being built in Nov in Argentina. Nest in old woodpecker (Picidae) hole or similar cavity at middle to upper level (generally c. 12-30 m) in tree, cavity usually partially filled and lined with dead leaves, small twigs and various other plant matter (e.g. flower stalks); sometimes in same tree as *T. semifasciata*. Clutch size uncertain, probably 3 eggs; incubation by female, period thought to be c. 18-21 days; chicks fed by both sexes, nestling period c. 20-30 days.

Movements. No significant movements known.

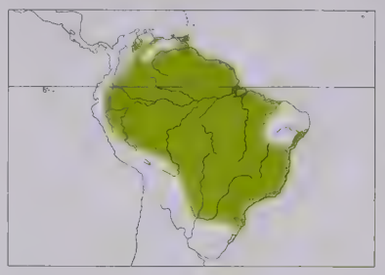
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Apparently more abundant in S part of range. Has a large range, within which much of its habitat remains relatively undisturbed. Occurs in numerous national parks and other protected areas.

Bibliography. Accordi *et al.* (2000), Anon. (1998a), Binford (1989), Boesman (1998), Brooks *et al.* (1993), Canevari *et al.* (1991), Clements and Shany (2001), Cory and Hellmayr (1927), Cracraft (1985), Darrieu & Camperi (1991), Di Giacomo (2004), Du Bus (1847), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Henderson (2002), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Hutto (1992), Kaup (1852), Kiff & Hough (1985), Lanyon (1985), Lee Jones (2004), Lowen *et al.* (1996), McKitrick (1985), Meyer de Schauensee (1966, 1982), Monroe (1968), de la Peña (1987, 1989), Prum *et al.* (2000), Ridgely (1981), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson (1997), do Rosário (1996), Short (1975), Sibley & Ahlquist (1985c), Sick (1993, 1997), Skutch (1969), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thomas (1979a), Tostain *et al.* (1992), Traylor (1977), Wetmore (1972), Willis (1980), Zimmer (1936b).

411. Black-tailed Tityra

Tityra cayana

French: Tityre gris **German**: Schwarznackentityra **Spanish**: Titira Colinegro



Taxonomy. [*Lanius*] *cayanus*, Linnaeus 1766, French Guiana.

Genus formerly included with *Pachyramphus* in the Cotingidae, but transferred to the present family on the grounds of several shared, derived similarities of the skull and syrinx. Because of their similarity to cotingids in respect of many other features, some authors prefer to treat both genera as representing a separate family (Tityridae) or to leave them in Cotingidae. Phylogenetic affinity of genus and of this species currently unknown; molecular investigation needed. Races differ considerably in plumage; has been suggested that they be treated as two separate species, but apparent intergrades occur in a belt from NE Brazil (Piauí) SW through Mato Grosso to Bolivia. Two subspecies recognized.

Subspecies and Distribution.

T. c. cayana (Linnaeus, 1766) - Venezuela, Trinidad, the Guianas, E Colombia, N Brazil (Amazon and tributaries E to Pará and Amapá), E Ecuador, E Peru and Bolivia.

T. c. braziliensis (Swainson, 1837) - NE, C & S Brazil (Maranhão, Piauí and Pernambuco S to Mato Grosso do Sul and N Rio Grande do Sul), N and E Bolivia (La Paz, Cochabamba, Santa Cruz), N, C & E Paraguay (primarily E of R Paraguay) and NE Argentina (S to E Formosa, E Chaco and Misiones, probably also Corrientes).

Descriptive notes. 20-22 cm; 69 g. Male nominate race has crown and side of head to below eye black, bare rosy-red facial skin around eye and on lores; upperparts pale silvery white or pearly grey; wings mostly black, tertials silvery grey; primary P9 greatly reduced in length, outermost primary normal; tail relatively short, entirely black; throat and underparts white, tinged with grey; iris dark; bill quite sturdy, slightly hooked, rosy red on basal half, black terminally; legs blackish. Distinguished from *T. semifasciata*, mainly by black on head extending over crown, no white in tail. Female has more dusky brownish crown, mostly dingy brownish-grey upperparts with coarse dark streaks, especially on nape and back, narrow but prominent dusky streaking on whitish breast. Juvenile undescribed. Race *braziliensis* is distinctive: male generally more white than nominate, facial skin reddish-purple, bill mostly black with just base reddish-purple; female lacks black cap, has head and upperparts more greyish-brown, coarse black streaking on head and back, underparts more buffy-tinged and much more densely streaked with black. VOICE. Generally not very vocal. Typical call a soft, buzzy and nasal grunting or croaking "ed", "urt", "wenk" or "rek", usually as double notes or in triplets, "weenk, weenk, weenk"; often calls in flight.

Habitat. Borders of humid lowland (*terra firme* and *várzea*) and foothill forest, tall and relatively open second growth along rivers, gallery forest, tall snags, plantations, and clearings with scattered trees. Mostly to c. 500 m, occasionally higher, to 1100 m.

Food and Feeding. Mostly frugivorous; also takes a fair amount of insects, mostly for feeding to offspring. In pairs or in small, loosely connected groups, and sometimes singly; aggressive towards other birds, and rarely social. Usually perches high on a bare limb, often in the open. Food taken by perch-gleaning or hover-gleaning. A main seed-disperser of *Cabralea canjerana* (Meliaceae) in SE Brazil.

Breeding. Nests in Mar (Meta), Jul and Nov (Leticia) and birds in breeding condition in Jun (Caquetá) in Colombia; nests in Feb, Mar and Nov in Trinidad, Mar in Ecuador, Oct and Nov in Argentina and Dec in Brazil. Nest in natural tree cavity, broken stub or old woodpecker (Picidae) hole at middle to upper level, one in Ecuador c. 9 m up in a *Cecropis* tree adjacent to oxbow lake; cavity usually lined or filled with dead leaves, small twigs and sometimes various other plant material. Clutch size uncertain, probably 3 eggs; incubation by female, period probably c. 18-21 days; chicks fed by both parents, nestling period probably c. 20-30 days. Parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded.

Movements. None known.

Status and Conservation. Not globally threatened. Fairly common to common. Has a large range, within which extensive areas of suitable habitat are still in relatively pristine condition. Occurs in many national parks and other protected areas.

Bibliography. Anon. (1998a), Bates & Parker (1998), Brooks *et al.* (1993), Canevari *et al.* (1991), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Darrieu & Camperi (1991), Di Giacomo (2004), Dubs (1992), Ffrench (1991), Fontana *et al.* (2000), Friedmann (1948), Friedmann & Smith (1955), Guix (1995), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Herklots (1961), Hill & Greeney (2000), Hilty (2003), Hilty & Brown (1986), Irestedt *et al.* (2001), Johansson (2002), Lanyon (1985), Lowen *et al.* (1996), McKitrick (1985), Meyer de Schauensee (1966, 1982), Miserendino (1998), Narosky & Yzurieta (1993), Novaes (1978a, 1992), de la Peña (1989), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Robinson (1997), do Rosário (1996), Schulenberg *et al.* (2001), Short (1975), Sibley & Ahlquist (1985c), Sick (1993, 1997), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Temple (2002), Terborgh *et al.* (1984), Tostain *et al.* (1992), Traylor (1977).

Genus *XENOPSARIS* Ridgway, 1891

412. White-naped Xenopsaris

Xenopsaris albinucha

French: Bécarde à nuque blanche **German**: Kappenbekarde **Spanish**: Anambé Chico
Other common names: Reed Becard, Xenopsaris

Taxonomy. *Pachyramphus albinucha* Burmeister, 1869, near Bueno Aires, Argentina.
Affinities uncertain. Early taxonomists hypothesized that genus was close to *Knipolegus*, *Serpophaga* and *Suiriri*, whereas later ones included it within the family Cotingidae and placed it close to *Pachyramphus*. More recent systematic studies indicate that, on basis of cladistic analysis of morphology, this species may be the closest living relative of latter genus (but still with somewhat uncertain affinity); has been suggested that the two genera should be merged, but in most treatments monotypic genus is retained for present species because of its significant differences (including much smaller size, different tarsal scutellation, short pointed primary P9, absence of strong sexual dimorphism, nest type). Has also been proposed that both genera and several others (*Laniocera*, *Laniisoma* and *Iodopleura*) comprise a natural group, known as the "*Schiffornis* assemblage". Two subspecies recognized.
Subspecies and Distribution.
X. a. minor Hellmayr, 1920 - W & C Venezuela (extreme W Falcón, NE Lara and W Apure E to Anzoátegui and N Bolívar); probably also in parts of NE Colombia (Arauca and Vichada).
X. a. albinucha (Burmeister, 1869) - Guyana, N, NE & E Brazil (Roraima; Maranhão, Piauí, Ceará, Pernambuco and W Alagoas S through interior, including W Bahia, to Mato Grosso and Mato Grosso do Sul), N & E Bolivia (Beni, Santa Cruz), W & C Paraguay (Chaco), NE Argentina (E from Tucumán and Córdoba, S to Santa Fe, Entre Ríos and Buenos Aires) and extreme NW & W Uruguay.

Descriptive notes. 12·5-13 cm; 10·2 g. Male has crown glossy black with bluish sheen; lores and lower forehead markedly white, side of head and neck basically white but face more dirty-looking (greyish-tinged auriculars), light-coloured eyering; nape pale grey, sometimes greyish-white to white band separating crown and upper back (usually difficult to see in field); upperparts mostly greyish-brown, rump and scapulars more greyish (but still obvious brownish tinge); wings more dusky brown than grey, narrow whitish edging on inner remiges and wing-coverts; primary P9 shorter and pointed; tail dusky brownish, pale lateral edges on two outermost rectrices, pale brownish tips; mostly pure white with creamy tinge below, except for faint greyish tinge on chest and slightly more yellowish belly; iris dark brown or seal; bill stout, upper mandible black, lower mandible more plumbeous; legs black. Differs from somewhat similar *Pachyramphus rufus* mainly in smaller size, longer tail, thinner bill, white margins on inner remiges, whiter (not grey) underparts, and more brownish tinge above. Female resembles male but may be slightly duller overall, and crown with brownish-chestnut tinge. Immature has stronger brownish tinge on crown, greyish nape, slight brownish tinge on upperparts (sometimes scalloped appearance), creamy yellowish belly. Race *minor* is more or less identical in plumage to nominate, but significantly smaller: male wing 60-62 mm and tail 53-57 mm (respectively, 64-66 mm and 58-61 mm in nominate). Voice. Typical song, heard most often during rainy season (but at all hours of day), rather delicate, given at long intervals, does not carry very far, described as high-pitched, thin and hesitant "teep, tre'e'e'e'e'a eea wu'u'u'e'e'e-e-e-e-e-p" or "twip, tsiweeé, tseee, ti-ti-ti-ti", with initial trill rising and then falling and last trill long, quavering and ascending; sometimes pattern varied and/or only part of song given; also described as squeaky and slightly undulating screech.
Habitat. Locally in *caatinga*, brushy riparian areas, light woodland and borders, isolated groves of trees around ranch buildings, also borders of dry gallery forest and sedges along riverbanks, tall herbaceous vegetation, and largely open areas with scattered trees; usually near water or in damp areas. To 550 m.
Food and Feeding. Insects recorded in diet. Singly or in pairs, partners typically remaining well apart. Generally rather quiet and inconspicuous, usually perched in erect, upright posture in outer foliage of trees. Typically, sallies short distances of c. 0·5-1·5 m; hover-gleans insects from tops of leaves or sally-strikes insects from leaves without pausing; sometimes makes acrobatic chases after prey that is attempting to escape. Often forages at lower levels, and regularly takes prey from the ground.
Breeding. Jun-Sept in Venezuela, with active nest in Jul and incubation in late Aug in W Venezuela; Oct-Jan in Argentina. Nest cup-shaped, c. 4·5 cm across, 4 cm tall and 1·8 cm deep, walls c. 0·5 cm thick, composed primarily of woven plant fibres and some rootlets, placed c. 5-15 m above ground (but likely also lower) in fork of tree (with very minor to no significant attachment) in tree c. 15-20 m tall. Clutch 3 eggs. No further information.
Movements. Resident. Possibly some movement in S of range, e.g. Bolivia.
Status and Conservation. Not globally threatened. Rare to uncommon, and local. Perhaps most common in pantanal of W Mato Grosso do Sul, but even there not regular. Has been recorded in Beni Biosphere Reserve and Madidi National Park, in Bolivia, San Luis and Ybycuí National Parks, in Paraguay, and Maracá Ecological Station (Roraima) and Serra da Canastra National Park, in Brazil.

Genus *PACHYRAMPHUS* G. R. Gray, 1840

413. Green-backed Becard

Pachyramphus viridis

French: Bécarde verte **German**: Grünrückenbekarde **Spanish**: Anambé Verdoso

Taxonomy. *Tityra viridis* Vieillot, 1816, Paraguay.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Previously considered conspecific with *P. xanthogenys*, but differs in plumage and habits and is widely separated geographically. Two subspecies recognized.
Subspecies and Distribution.
P. v. griseigularis Salvin & Godman, 1883 - SE Venezuela (E Bolívar), Guyana (Mt Roraima) and locally in N Brazil (lower R Tapajós and E on both banks of Amazon to Marajó I).
P. v. viridis (Vieillot, 1816) - NE, WC & S Brazil (from Ceará, Rio Grande do Norte and S Piauí S to Tocantins, S Mato Grosso and Rio Grando do Sul), E & S Bolivia (NE Santa Cruz S to E Chuquisaca and Tarija), Paraguay, N Argentina (S to Tucumán, Santa Fe and Entre Ríos) and N & E Uruguay.

Descriptive notes. 14·5-15 cm; 21 g. Male nominate race has glossy black crown, whitish lores, face and throat, narrow yellowish eyering; side of head, and neck and nuchal collar pale grey; upperparts largely rather bright olive; flight-feathers and tail dusky olive, remiges with olive edges; broad pectoral band bright yellow to greenish or olive-yellow merging into rest of underparts greyish-white with buffy tinge; iris dark; bill rather broad, slightly hooked, pale bluish-horn; legs dark or greyish. Differs from *P. xanthogenys* in grey face and throat, brighter pectoral band. Female is similar in pattern to male, but has greyish lores with dusky tinge, greyer face, crown dull olive, upperparts pale olive, largely rufous-chestnut lesser wing-coverts, usually somewhat more dusky below, with pectoral band sometimes more obscure. Race *griseigularis* differs from nominate in lacking pale nuchal collar, male having less distinctive pectoral band, female almost no pectoral band. Voice. Typical song a series of melodic whistles, "trididideédeédeédeé", often with cresendo, or a sequence of c. 6 "ew-léé" notes; typical call a fast, thin and nasal "q-wink, q-wink" that rises in pitch, may be repeated up to twelve times; also a "jew" call note.
Habitat. Tall moist to humid forest, lighter woodland, gallery forest, edges, shrubby borders, and clearings or broken forest areas with scattered trees. To 1000 m.
Food and Feeding. Insects. Observed singly or in pairs, partners often remaining well apart; often mingles in mixed-species foraging flocks. Forages at varying heights in more open parts of trees, hopping casually and often pausing to peer intently, before reaching from perch or sallying a short distance to snatch or hover-glean insects from foliage.
Breeding. Oct-Dec in Argentina. Nest rather untidy, bulky and globular, c. 25 cm high, 18-24 cm wide, entrance hole on side or near bottom, hole diameter 3·5-5 cm, inner chamber c. 8·5 cm across, composed of dead leaves, fibres, moss, etc.; generally hanging from drooping branch or wedged in fork among outer branches at middle to upper level of tree. Clutch 2-4 eggs; incubation by female, period thought to be c. 18-21 days; chicks fed by both sexes, nestling period c. 20-30 days.
Movements. None known.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in Noel Kempff Mercado National Park, in Bolivia, Caaguazú, San Rafael and San Luis National Parks, all in Paraguay, Iguaçu and Itatiaia National Parks, in Brazil, Cerro Corá National Park, in Uruguay, and Calilegua National Park, in Argentina.
Bibliography. Babarskas, Haene & Pereira (2003), Babarskas, Veiga & Filiberto (1995), Brooks *et al.* (1993), Canevari *et al.* (1991), Cracraft (1985), Di Giacomo (2004), Dubs (1992), Hayes (1995), Hellmayr (1929), Hennessey & Gómez (2003), Hilty (2003), Lanyon (1985), López (1997), Lowen *et al.* (1996), McKitrick (1985), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Nores *et al.* (2000), de la Peña (1987, 1989, 1997), Prum *et al.* (2000), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Short (1975), Sick (1993, 1997), Silveira *et al.* (2003), Stotz *et al.* (1996), Wetmore (1926), Willis & Oniki (1990).

414. Yellow-cheeked Becard

Pachyramphus xanthogenys

French: Bécarde à joues jaunes **German**: Gelbwangenbekarde **Spanish**: Anambé Cariamarillo

Taxonomy. *Pachyrhamphus xanthogenys* Salvadori and Festa, 1898, River Zamora, Ecuador.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Previously considered conspecific with *P. viridis*, but differs in plumage and habits and is widely separated geographically. Validity of race *peruanus* uncertain. Two subspecies recognized.
Subspecies and Distribution.
P. x. xanthogenys Salvadori & Festa, 1898 - E Ecuador (E slope of Andes from W Sucumbíos S to Zamora-Chinchipe) and N Peru (Cajamarca, Amazonas); probably also extreme S Colombia.
P. x. peruanus Hartert & Goodson, 1917 - C & SE Peru (Huánuco, Pasco, Junín, Madre de Dios).
Descriptive notes. 14·5 cm. Male has glossy black crown, bright olive nape; white lores, partial yellow eyering; face mostly bright yellow to greenish-yellow, becoming yellowish-olive on side of throat; upperparts bright olive; wings blackish, broad pale olive edging on wing-coverts and

On following pages: 415. Barred Becard (*Pachyramphus versicolor*); 416. Slaty Becard (*Pachyramphus spodiurus*); 417. Cinereous Becard (*Pachyramphus rufus*); 418. Chestnut-crowned Becard (*Pachyramphus castaneus*); 419. Cinnamon Becard (*Pachyramphus cinnamomeus*); 420. White-winged Becard (*Pachyramphus polychopterus*).

inner remiges; tail dusky olive; neck side, throat and chest bright yellow, becoming more yellowish-olive on breast and whitish on belly; iris dark; bill rather broad, slightly hooked, pale bluish-horn; legs dusky or greyish. Female is similar in pattern to male, but has forecrown blackish and remainder of crown and nape more grey or greyish-olive, lores greyish-olive, face pale greyish (sometimes some yellowish on cheek), lesser wing-coverts rufous-chestnut, throat greyish, pectoral band greenish and lower breast more pale olive, and belly white with some greyish wash along sides and flanks. Race *peruanus* is slightly brighter on face and breast. Voice. Typical male song, usually conducted from well-concealed high perch, a distinctive series 2-3 seconds long of soft and subdued musical whistles, "du-du-dididididi" or "du-de-de-de-dididididi", often given at long intervals and preceded by one or more upslurred "te-wik" notes.

Habitat. Borders of humid montane and foothill forest, woodland edges, and clearings with scattered tall trees; considered a non-forest species, only rarely observed deep within continuous forest. Primarily at 650-1700 m, perhaps occasionally lower.

Food and Feeding. Usually observed in pairs; does not usually mingle with mixed species flocks. Generally rather sluggish and inconspicuous. Forages at varying heights in trees with dense foliage, but usually at higher levels and always well above the ground.

Breeding. Nest bulky and globular, entrance hole on side or near bottom, composed of dead leaves, fibres, moss, and so on; generally hanging from drooping branch or wedged in fork among outer branches at middle to upper levels of tree. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to fairly common; probably often overlooked. In Ecuador, common along road to Loreto N of Archidona and in the Zumba area, and occurs also in Podocarpus National Park. In Peru, recorded recently at c. 600 m near Tamborapa, in Cajamarca, well N of known range of race *peruanus*; possible that nominate race, from farther N, was involved; also, recently recorded (and photographed) at 900 m above Hacienda Amazonia, near Manu National Park and Biosphere Reserve.

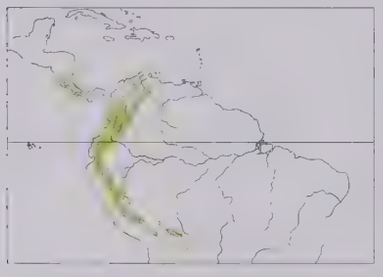
Bibliography. Begazo *et al.* (2001), Clements & Shany (2001), Hellmayr (1929), Lanyon (1985), McKitrick (1985), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Williams & Tobias (1994).

415. Barred Becard

Pachyramphus versicolor

French: Bécarde barrée **German**: Wellenbekarde **Spanish**: Anambé Barrado

Taxonomy. *Vireo versicolor* Hartlaub, 1843, "Bogotá", Colombia.



Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Variation among races negligible; has been suggested that *meridionalis* should perhaps be merged with nominate. Three subspecies currently recognized.

Subspecies and Distribution.

P. v. costaricensis Bangs, 1908 - Costa Rica and W Panama (Chiriquí).

P. v. versicolor (Hartlaub, 1843) - Sierra de Perijá, and Andes from SW Venezuela (S from SE Lara) and Colombia (S of Valle in W Andes, S from Norte de Santander in C range, and from SE Santander and NE Boyacá S on both slopes of E cordillera) S to C & SE Ecuador (S on W slope to Chimborazo and on E slope to Zamora-Chinchipe).

P. v. meridionalis Carriker, 1934 - SE Ecuador (Zamora-Chinchipe), Peru (N Amazonas S to N Puno, including extension on Pacific slope in SW Cajamarca) and NW Bolivia (La Paz, Cochabamba).

Descriptive notes. 11·5-13 cm; 14-17 g. Male nominate race has crown, nape and back mostly glossy black, sometimes more olivaceous, rump and uppertail-coverts slate-grey; lores yellow, face and neck side greenish-yellow with fine light dusky barring; wings more or less black and white, scapulars and lesser and median wing-coverts largely white with prominent black edging, greater coverts and inner remiges black with white margins; tail dusky slate, white edges at tips of lateral rectrices; throat greenish-yellow, fading to whitish below, underparts with some light dusky barring (except on centre of belly); iris dark; bill rather stout, upper mandible black, lower mandible bluish-grey; legs grey. Female is mostly olive to olive-green above, crown more slate-grey, face olive with yellow eyerings, wings blackish but with quite prominent and mostly rufous-chestnut wing-coverts, buff margins on tertials and rufous edgings on most secondaries; pale yellow to greenish-yellow below, with dull narrow dusky barring on throat, breast and sides. Immature male is much duller, more greenish overall, with yellowish eyerings like female; dull olive-green mixed with sooty black above, except for dark sooty-grey crown and hindneck; scapulars and wings more greenish-yellow, underparts mostly dull greenish-yellow with faint dusky barring except on belly. Races exhibit rather slight degree of variation in coloration of upperparts: *costaricensis* has distinctly more yellowish-olive back and rump, but variable, and some have black back like nominate; *meridionalis* is said to be less barred below. Voice. Typical call a soft, high-pitched "weet weet weet", given incessantly, a soft "tu-duu" whistle, or more excited "tseep tseep tseep tseep"; also high-pitched but weak trill and various twittering notes; male song a soft melodic "pee-pee-pee-pee-pipipipeh", "we-pe-pi-pi-pi-pi" or "we-pi-pi-ti`ti`tre`tre`ree", rising and then falling at end, generally given at long intervals, and sometimes changing to faster and rising "trrrdididee" or "tree, tree-dee-dee-dee-dee" with pause of up to 10 seconds after first note.

Habitat. Canopy or borders of humid and wet montane forest, and edges of lighter mature secondary woodland or semi-open areas at lower elevations. Mostly 1500-2900 m, but recorded as low as 400 m, and as high as 3050 m in Ecuador (Cerro Toledo) and even 4000 m in Colombia (Magdalena Valley).

Food and Feeding. Arthropods, also small fruits such as *Trema* and *Urera*. Singly, in pairs, or in small family groups following breeding season; regularly accompanies mixed-species foraging flocks. Perches fairly upright, at lower to upper levels, usually 1-5 m, rarely higher where vegetation is dense. Actively sally-gleans insects from vegetation, regularly striking against foliage or hovering briefly; also hops along branches and perches on leaves and epiphytes; also hover-gleans items.

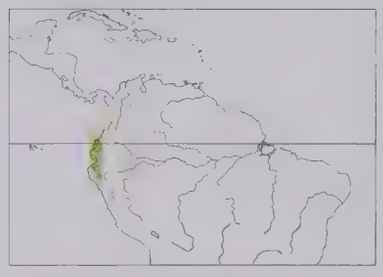
Breeding. Apr-Jun in Costa Rica; birds collected in breeding condition in Jun (Antioquia) and nestlings in May and Oct (W Andes above Cali) in Colombia; in Ecuador, fledging occurs in May in NW, and juveniles recorded in Dec in NE. Nest is bulky and more or less globular, c. 30 cm in diameter, with entrance hole near bottom, composed primarily of moss and vines and lined with leaves, generally saddled or wedged in fork of slender branches towards outside and upper level of tree at 2-15 m, occasionally as high as 23 m, and often outside continuous forest. Clutch 2-3 eggs; incubation by female, probably c. 18-21 days; chicks fed by both parents, nestling period c. 20-30 days.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in Rancho Naturalista and Tapantí National Park, in Costa Rica, Sierra Nevada National Park, in Venezuela, almost all national parks in Ecuadorian Andes, Machu Picchu Historical Sanctuary, in Peru, and Madidi National Park, in Bolivia.

Bibliography. Anon. (1998a), Baez *et al.* (1997), Blake (1958), Butler (1979), Chapman (1921), Clements & Shany (2001), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Krabbe *et al.* (1997), Lanyon (1985), McKitrick (1985), Meyer de Schauensee (1982), Miller (1963), Prum *et al.* (2000), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Salaman (1994), Sibley & Ahlquist (1985c), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Walker (2001), Wetmore (1972), Williams & Tobias (1994).

416. Slaty Becard



Pachyramphus spodiurus

French: Bécarde ardoisée **German**: Schieferbekarde **Spanish**: Anambé Pizarra

Taxonomy. *Pachyramphus spodiurus* P. L. Sclater, 1860, Babahoyo, Los Ríos, Ecuador.

Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to, and perhaps conspecific with, *P. rufus*; the two appear to replace each other geographically and, arguably, constitute a zoogeographical species. Monotypic.

Distribution. W Ecuador (W Esmeraldas and Pichincha S to W Loja) and extreme NW Peru (Tumbes, Piura, Cajamarca).

Descriptive notes. 14 cm. Male is mostly slaty grey above, whitish supraloral spot, crown and nape black, nape with some slaty grey mixed in, sometimes some black on back; wings blackish, narrow white margins on remiges, black patch on primary coverts; tail dusky black, sometimes narrow pale greyish edging; grey below, throat slightly paler grey; iris dark; bill blackish, more pale greyish towards base of lower mandible; legs blackish. Distinguished from *P. homochrous* by smaller size, smaller bill, pale supraloral spot, white margins on wing feathers. Female is entirely bright cinnamon-rufous above, darker on crown, small whitish-grey supraloral spot, lighter buff-cinnamon face; most remiges blackish with distinctive rufescent margins (folded wing appears largely cinnamon-rufous), tail cinnamon; mostly whitish cinnamon-buff below, distinctly more buffy tinge across chest and upper breast, throat more whitish with buffy tinge on sides. Voice. Typical male song is a short, fast series of rather musical notes, "tu, tu, tee tee-tititititi", that starts slowly, rapidly accelerates and increases in pitch and volume; also gives a short (2-3 seconds) slurred trill that starts low before taking on more even pitch.

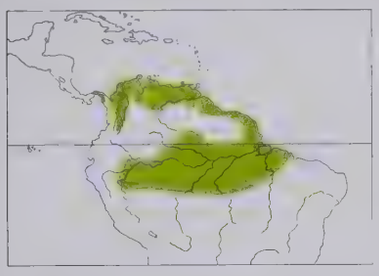
Habitat. Semi-humid and deciduous woodland, scrubby areas, clearings and plantations with some tall scattered trees, and dry washes in arid scrub; also locally in more humid areas that have been deforested. Mostly below 600-750 m, locally to 1100 m.

Food and Feeding. Largely unknown. Most often observed in pairs. Perches in canopy or subcanopy; regularly forages close to the ground.

Breeding. No information. Thought to breed in Jan-Mar.

Movements. Resident.

Status and Conservation. ENDANGERED. Restricted-range species: present in Tumbesian Region EBA and Marañón Valley EBA. Rare to locally uncommon, and very local; probably often overlooked. Forest habitats within the Tumbesian region are being rapidly destroyed, degraded and fragmented as a result of timber extraction and livestock grazing. In W Ecuador below 900 m, deforestation rates of 57% per decade from 1958 to 1988, and predicted that virtually all lowland forest outside protected areas will soon have disappeared. Even protected areas are affected by logging, livestock grazing, illegal settling and habitat clearance by people with land rights. Marañón drainage has likewise lost most of its original forest cover through logging and agricultural expansion, and no protected areas exist. Consequently, the species' population of perhaps several thousand individuals has suffered a serious decline within its small range of 2060 km², and very few recent records exist, particularly in N of its Ecuadorian range. Historically known from 29 localities, but recent records only from Tumbes Reserved Zone (within the Northwest Peru Biosphere Reserve, in Peru), which is the only sufficiently large protected area for long-term survival, and from several sites in Ecuador, including the much smaller Cerro Blanco Forest Reserve, Loma Alta Ecological Reserve, Río Palenque Science Centre, and Manta Real (designated for protection), as well as several unprotected sites, e.g. near Pedro Vicente Maldonado (Pichincha), Arenillas (El Oro) and Puyango (Loja), some recent reports from relatively degraded areas, however, suggest that the species may also survive outside protected areas.



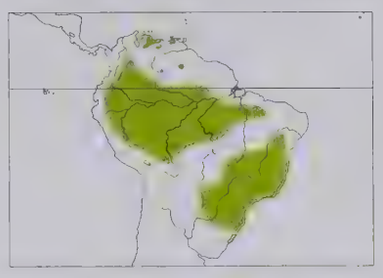
Bibliography. Berg (2002a), Best & Kessler (1995), Butler (1979), Clements & Shany (2001), Collar *et al.* (1992), Cracraft (1985), Lanyon (1985), McKitrick (1985), Meyer de Schauensee (1982), Pople *et al.* (1997), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Wege & Long (1995), Zimmer (1936b).

417. Cinereous Becard

Pachyramphus rufus

French: Bécarde cendrée **German**: Graubekarde **Spanish**: Anambé Cinéreo

Taxonomy. *Muscicapa rufa* Boddaert, 1783, Cayenne, French Guiana.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to, and perhaps conspecific with, *P. spodiurus*; the two appear to replace each other geographically and, arguably, constitute a zoogeographical species. Two subspecies recognized.
Subspecies and Distribution.
P. r. rufus (Boddaert, 1783) - W Panama (both slopes of Canal area, lower and middle Bayano Valley, and Darién), Colombia (Magdalena and Guajira S to Valle de Cauca and N Huila, also E of Andes in at least Norte de Santander and Leticia), W & N Venezuela (E, generally N of R Orinoco, to Sucre, Monagas and N & E Bolívar), the Guianas, and Brazil (middle and lower Amazonia from Manacapurú and Tefé E to Amapá, NE Pará and Maranhão).
P. r. juruanus Gyldenstolpe, 1951 - E Peru (Loreto) and W Amazonian Brazil (SW Amazonas).



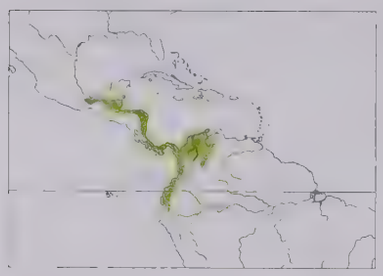
Descriptive notes. 12·9-14 cm; 18·5 g. Male has white lower forehead and loral area, dusky spot in front of eye, glossy black crown; upperparts mostly pearl-grey, sometimes with faint olive tinge, especially on upper back; wings blackish, narrow white margins on outer remiges, broader edging on inner remiges and wing-coverts; tail slaty grey, sometimes narrow whitish edging on tips of rectrices; throat whitish, underparts light greyish, darkest on chest and upper breast, sometimes with slight pale yellowish tinge; iris dark; bill blackish; legs greyish. Differs from similar *Xenopsaris albinucha* in less slender build, shorter tail, more greyish (less pure white) underparts, greyer (less brownish-tinged) upperparts and wings. Female is bright cinnamon-rufous above, crown often darker and more chestnut, lores whitish to whitish-grey, face light buffy cinnamon, wing feathers blackish with distinctive rufescent margins, greater coverts more uniformly cinnamon-rufous (folded wing appears largely cinnamon-rufous), tail cinnamon; whitish throat with cinnamon-buff tinge on sides, distinctly more buffy wash across chest and upper breast, more whitish on lower underparts. Races differ minimally: *juruanus* may have more extensive black on crown than nominate, extending farther on to nape, female with more extensive cinnamon-rufous below than nominate. Voice. Both sexes appear to have rather large repertoire of melancholy songs; typical song a fast series of musical notes, e.g. "twee, twee, twee-twee-twee-tweetweeteeteetititi", rising in pitch and accelerating to almost a trill towards end; also a sweet and strongly inflected "tuweé-tuweé-tuweé-tuweé-wee" whistle of more or less constant pitch; also gives thin, weak trill that rises sharply, but slows and descends towards end, also similar-sounding but shorter "twee-twee-twee-tweedo"; birds in Delta Amacuro (E Venezuela) said to give slightly hoarse "we'p-pe-pe-pe-pe-pe-pe-pé-wé-o" that runs up scale. Typical calls include high-pitched and metallic-sounding "eeeeé" that rises slightly at end, and buzzy "breez-det".
Habitat. Dry to moist areas, including light and open scrubby secondary woodland, clearings with groves of tall trees, lowland deciduous woodland, low scrub, cultivated areas and pastures with scattered trees, riparian woodland, mangroves, and forest borders; generally stays well away from continuous primary forest, and seems to prefer drier areas. To 1500 m.
Food and Feeding. Arthropods, including caterpillars; also small fruits and berries. Singly or in pairs; infrequently joins mixed-species foraging flocks. Perches in canopy and at lower levels; changes perch frequently, and actively peers about the vegetation. Typically perch-gleans or makes upward sally-gleans to take food items from foliage and branches.
Breeding. Nest found in Jun in Venezuela (Aragua); birds in breeding condition in Apr-Oct and Feb N Colombia. Nest bulky and globular, entrance hole on side, composed primarily of leaves and grass, generally wedged in fork among outer branches and usually at upper level of tree. Clutch 2-5 eggs; incubation by female, period c. 18-21 days, nestling period c. 20-30 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to common. Apparently most abundant in the Guianas and least abundant in Panama. Range of race *juruanus* possibly extends N into extreme SE Ecuador; specimen records from Zamora-Chinchipe require confirmation of identification. Occurs in Darién National Park, in Panama, and Anavilhanas Ecological Station and Jaú and Tapajós National Parks, in Brazil.
Bibliography. Anon. (1998a), Bangs & Penard (1918), Boggs (1961), Butler (1979), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Delgado (1985), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1985), McKitrick (1985), Meyer de Schauensee (1982), Oniki & Willis (1982), Oren & Parker (1997), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain (1980), Tostain *et al.* (1992), Zimmer (1936b).

418. Chestnut-crowned Becard

Pachyramphus castaneus

French: Bécarde à calotte rousse **German**: Graunackenbekarde **Spanish**: Anambé Castaño

Taxonomy. *Tityra castanea* Jardine and Selby, 1827, Rio de Janeiro, Brazil.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Possibly closest to to *P. cinnamomeus*; the two are sometimes treated as a single zoogeographical species, essentially replacing each other geographically, but slight morphological differences between them considered by most authorities sufficient for treatment as distinct species. Five subspecies recognized.
Subspecies and Distribution.
P. c. intermedius Berlepsch, 1879 - N Venezuela (Falcón and Lara E to Sucre).
P. c. parui Phelps, Sr & Phelps, Jr, 1949 - base of Cerro Parú, in Amazonas (S Venezuela).
P. c. saturatus Chapman, 1914 - SE Venezuela (SE Bolívar), E Colombia (R Dudita and Vaupés S to Meta), E Ecuador, NE & E Peru (Loreto, Cuzco), N Brazil (Amazonas, Acre and Rondônia E to Manacapurú and R Purús) and N Bolivia.
P. c. amazonus J. T. Zimmer, 1936 - N Brazil (both banks of Amazon from E Amazonas and Pará E to R Tocantins and Maranhão).
P. c. castaneus (Jardine & Selby, 1827) - NE , SE & S Brazil (N Bahia S to SE Goiás, Mato Grosso do Sul and N Rio Grande do Sul), SE Paraguay and NE Argentina (Misiones).



Descriptive notes. 14-14·8 cm; 17·3 g. Nominate race is largely cinnamon-rufous above, crown darker and more chestnut with somewhat scaly appearance (feathers having paler tips); lores more or less dusky; buff-whitish supraloral spot becomes grey above eye, extending as postocular stripe around nape; face pale cinnamon; wings mostly dusky cinnamon, remiges more dusky with pale cinnamon-rufous margins (wider on inside edge), wing-coverts more dusky rufous; tail cinnamon-rufous; mostly pale cinnamon-buff below, throat paler; iris dark; bill blackish; legs dusky. Distinguished from *P. cinnamomeus* by narrow grey band encircling nape. Sexes similar. Races differ only slightly: *saturatus* has darker and more chestnut upperparts, perhaps greyer and less scaled-looking crown; *amazonus* and *intermedius*; perhaps slightly paler above than nominate, especially on tail; *parui* is darker overall, has more dusky chestnut crown. Voice. Typical song a series of soft, thin, casual, rather musical whistles, e.g. "teeeuw-teeu-teeu" or "teeeer, tee, tee", 1-5 of each note in a series; also soft, lamenting, descending "deeeeu, deeu-dee-de-de" with variable number of end notes, usually given at infrequent intervals; also ascending tremolo "tewi, i, i, i, i, i, i" or sequence of high "bi-bi-bi-bi" notes; explosive "tic" said to occur sometimes during breeding season in interactions between mates, may be a mechanical sound produced by modified tips of outer rectrices.
Habitat. Borders of dry to humid lowland forest, including both *terra firme* and *várzea*, adjacent clearings with at least some scattered tall trees, light second-growth woodland, riparian forest, and coffee plantations. Primarily below 1000 m, locally to 1500-1700 m.
Food and Feeding. Large insects, including caterpillars; occasionally berries. Singly, more often in pairs; generally does not join mixed-species foraging flocks. Often remains high above the ground, tending to perch on fairly open inner branches; rather sluggish, and frequently nods the head. Perch-gleans or makes short sallies to snatch or hover-glean items from middle to upper levels.
Breeding. Birds in breeding condition and juveniles recorded in May in Colombia (Vaupés); nests found in Mar and Jul in Ecuador, and Oct and Feb in Argentina. Nest messy, bulky, and globular, entrance hole near bottom facing downwards, composed primarily of grass and various plant fibres, one nest (Argentina) 23-25 cm in diameter, entrance hole 3·5 cm, inner chamber 8 cm in diameter; generally wedged in fork among outer branches at middle to upper levels of emergent tree. No other specific information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to locally common. Occurs in several seemingly disjunct populations; apparently rarer in Ecuador and Colombia than elsewhere, or perhaps often overlooked. Occurs in many national parks and other protected areas throughout its range, e.g. Henri Pittier National Park, in Venezuela, Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, Pilón Lajas Biosphere Reserve and Madidi National Park, in Bolivia, San Rafael and San Luis National Parks, in Paraguay, and Iguaçu, Itatiaia, Jaú, Serra da Canastra, Tapajós and Tijuca National Parks, all in Brazil.
Bibliography. Allen (1995), Brooks *et al.* (1993), Butler (1979), Canevari *et al.* (1991), Chapman (1914), Clements & Shany (2001), Cracraft (1985), Greeney *et al.* (2004), Haffer (1974), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Lanyon (1985), Lowen *et al.* (1996), McKitrick (1985), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Oren & Parker (1997), Parker (1997), de la Peña (1987, 1989), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer (1936b).

419. Cinnamon Becard

Pachyramphus cinnamomeus

French: Bécarde cannelle **German**: Zimtbekarde **Spanish**: Anambé Canelo

Taxonomy. *Pachyramphus cinnamomeus* Lawrence, 1861, Lion Hill, Panama.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Possibly closest to to *P. castaneus*; the two are sometimes treated as a single zoogeographical species, essentially replacing each other geographically, but slight morphological differences between them considered by most authorities sufficient for treatment as distinct species. Variation among races, especially in NE Colombia and NW Venezuela, requires closer inspection. Four subspecies recognized.
Subspecies and Distribution.
P. c. fulvidior Griscom, 1932 - SE Mexico (SE Veracruz and NE Oaxaca E to N Tabasco and S Chiapas), N Guatemala, C & S Belize, N Honduras and N & E Nicaragua S to W Panama (W Chiriquí, W Bocas del Toro).
P. c. cinnamomeus Lawrence, 1861 - E Panama (Cerro Azul/Jefe, Bayano Valley, and Darién), NW & W Colombia (S to N Tolima and S Antioquia, E to upper Sinu Valley, and E of Andes from Cataatumbo S to W Meta) and W Ecuador (S to NW Azuay and El Oro).
P. c. magdalenae Chapman, 1914 - N Colombia (lower Magdalena Valley and N Sucre, and E from lower Sinu Valley) and W Venezuela (S Maracaibo Basin, NW Táchira, W Mérida).
P. c. badius Phelps, Sr & Phelps, Jr, 1955 - W Venezuela (E slope of Andes in S Táchira).
Descriptive notes. 14-15 cm; 17-22 g. Plumage is mostly uniform rufous or chestnut-rufous to rufous-tawny above, slightly darker on crown and with narrow pale buff supraloral, dusky lores; wings more or less rufous, darker and more dusky primary coverts; tail basically rufous; ochraceous tawny to cinnamon-buff or to tawny-buff below, slightly paler and more whitish on throat and belly, some rufous tinge across breast; iris dark; bill more or less blackish, often paler greyish to greyish-flesh lower mandible; legs dark grey. Differs from similar *P. castaneus* mainly in less contrasting crown, no grey nuchal collar. Sexes similar; adult male has shorter and attenuated primary P9, normal in female. Immature is similar to adult but paler overall, except for brighter rufous upperparts, also more pale buff belly; immature male has unmodified P9. Races differ

only slightly: *magdalenae* is said to be more whitish and washed with cinnamon below; *badius* similar to previous but slightly darker; *fulvidior* is more richly coloured than nominate. Voice. Typical song a somewhat plaintive, reedy, usually fast or nearly trilled series of musical notes, e.g. "teedeedee-deedeedee", "cheei dee-dee", "deeeuu dew dew, dew, dew", often beginning or ending with "tew" note that drops in pitch, with second part of series (5-9 notes) either rising or falling, and sometimes shorter and slower overall; female song generally shorter and weaker. Typical calls also reedy, but shorter "swee-dwee-dwee" or "seer eeer eeur" series; also variety of high-pitched, thin and more plaintive "seeeeiu" slurred whistle-like calls.

Habitat. Edges and sometimes canopy of humid and evergreen forests, secondary-woodland borders, clearings with scattered tall trees, open to semi-open light woodland, plantations, riparian areas, sometimes mangroves; often near water. Lowlands to 500-800 m, but recorded to 1200 m in E Panama (Cerro Tacarcuna), 1300 m in Colombia, and 1500 m in Ecuador (Chimborazo).

Food and Feeding. Insects, including beetles (Coleoptera), katydids (Tettigoniidae), homopterans, ants (Hymenoptera), caterpillars; also spiders; also copious amounts of berries. Singly or in pairs, occasionally in small loose groups; occasionally joins mixed-species foraging flocks. Perches at middle to upper levels, and occasionally lower in second growth bordering primary forest; often bobs its head. Actively sallies short distances to glean insects and other items from foliage or twigs; seems more sluggish when consuming fruit for an extended period.

Breeding. Mar-Jul in Costa Rica; nest-building observed in early Mar (Buenaventura) and Apr-May (NW Santander) and birds in breeding condition in Jan-Oct in N Colombia. Nest rather messy, bulky and more or less globular, entrance hole at side, sometimes tunnel entrance near bottom, composed of dead leaves (especially bamboo), long brownish fibres, green moss, rootlets and various other vegetable material (seed down, etc.); generally wedged in fork near end of branch and towards outer canopy c. 1·5-15 m above ground high; often placed close to an active wasp nest. Clutch 3-4 eggs; incubation by female, period c. 18-21 days; chicks fed by both parents, nestling period probably 20-30 days.

Movements. Populations of race *fulvidior* in Mexico may be at least partially migratory, with apparent movement out of N parts of range about Sept-Feb. Seems to be quite sedentary elsewhere.

Status and Conservation. Not globally threatened. Uncommon to common. Nominate race possibly extends slightly farther S in Ecuador; single record from Loja (also one farther W, at Guayaquil) unconfirmed. Given this species' tolerance of converted habitat and its relatively large range, it is not considered to be at any risk. Occurs in many national parks and other protected areas, including at least seven well-known reserves in Central America.

Bibliography. Anon. (1998a), Berg (1994), Binford (1989), Boggs (1961), Brodkorb (1943), Butler (1979), Chapman (1914), Dearborn (1907), González-García (1993), Griscom (1932), Haffer (1974, 1975), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Lanyon (1985), Lee Jones (2004), McKitrick (1985), Monroe (1968), Phelps & Phelps (1955), Prum *et al.* (2000), Pulgarín (2002), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Skutch (1969), Slud (1960, 1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), West (1976).

420. White-winged Becard

Pachyramphus polychopterus

French: Bécarde à ailes blanches **German**: Weißbindenbekarde **Spanish**: Anambé Aliblanco

Taxonomy. *Platyrhynchos polychopterus* Vieillot, 1818, Bahia, Brazil.

Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinities of present species remain unknown. Races exhibit rather marked variation in plumage and, in some cases, also in voice; it has been suggested that more than one species may be involved. Eight subspecies currently recognized.

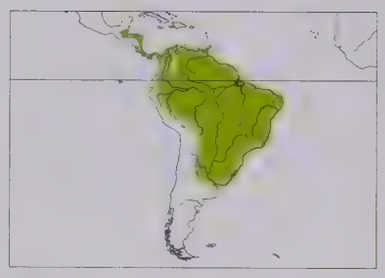
Subpecies and Distribution.

P. p. similis Cherrie, 1891 - C Guatemala E to S Belize (Toledo) and N Honduras, S to N Colombia (N Chocó).

P. p. cinereiventris P. L. Sclater, 1862 - N Colombia (Chocó except extreme N, E to Santa Marta, S to upper R Sinú and César).

P. p. dorsalis P. L. Sclater, 1862 - C & SW Colombia (S Antioquia and Cundinamarca S to SW Nariño) and NW Ecuador (E Esmeraldas, N & W Imbabura, and N Pichincha S to Mindo area).

P. p. tristis (Kaup, 1852) - NE Colombia (E of Andes from Norte de Santander S to Boyacá, probably to Guainía), Venezuela (except Cerro Duida, in S Amazonas), Trinidad and Tobago, the Guianas and NE Brazil (Roraima E to Maranhão and SE Pará).



P. p. nigriventris P. L. Sclater, 1857 - E Colombia (E of Andes in W Meta S to Vaupés), S Venezuela (S Amazonas at base of Cerro Duida), W Brazil (both banks of upper Amazon E to R Jamundá and E bank of R Madeira), E Peru (S of R Marañón) and N Bolivia (Beni).

P. p. tenebrosus J. T. Zimmer, 1936 - SE Colombia (SE Nariño and W Caquetá E to Amazonas), E Ecuador and NE Peru (N & W Loreto and San Martín).

P. p. polychopterus (Vieillot, 1818) - E Brazil (Piauí and Ceará S to Alagoas and Bahia).

P. p. spixii (Swainson, 1838) - NW Bolivia (Pando and La Paz E to Santa Cruz and S to Tarija), S & SE Brazil (Mato Grosso E to Espírito Santo, S to Rio Grande do Sul), Paraguay, N Argentina (S to Tucumán, Córdoba and N Buenos Aires) and Uruguay.

Descriptive notes. 14-15·5 cm; 19·5-21 g. Male nominate race has crown, nape and upperparts glossy black to almost bluish, back more plain; head side, nuchal collar and rump and uppertail-

coverts paler, slate-grey; wings black, prominent white scapulars, broad white margins on wing-coverts (wingbars), secondaries and tertials; tail rather long, graduated, black, broad white tips on all but central rectrices; throat and most of underparts slate-grey, same colour as head side, belly paler; iris dark; bill blackish or silver-grey with black tip, often paler on lower mandible; legs dark grey or plumbeous. Distinguished from *P. marginatus* and *P. albogriseus* by the lack of white or grey on lores, more extensive white in wings, generally darker appearance overall. Female has brownish-olive or greenish-olive upperparts, more brown on crown, pale whitish supraloral stripe, broken pale eyering, wings with broad buff-cinnamon margins on scapulars, wing-coverts and inner remiges, blackish tail with broad buff-cinnamon tips (especially on outer rectices); pale yellowish below, olive tinge on breast and sides, more greyish throat; lacks shorter and attenuated primary P9 of male. Juvenile both sexes resembles female, but quickly acquires immature plumage; immature male resembles female, but may have more greyish throat, black specks on head and back, and blackish distal area on central rectrices. Races vary mainly in colour of underparts: *dorsalis* is palest, has clear pale grey underparts, neck side, nuchal collar and rump, more white on wings including wingbars and broad margins on scapulars and inner remiges, female has more olivaceous upperparts; *tenebrosus* is completely black, more sooty below (blackest in E Ecuador and adjacent areas), glossier above (especially crown), two bold white wingbars (upper bar broader than lower), and broad white tips on outer rectrices, female has more rufescent upperparts; *nigriventris* is all black above and below, white edging only on wing-coverts and tail tips, female is more greyish-olive (not light brown) above; *tristis* similar to previous, but underparts slaty grey, with some white freckling on centre of belly; *cinereiventris* similar to previous, but smaller, and more uniform grey below; *similis* like previous, but smaller, and paler grey below; *dorsalis* similar to *cinereiventris* but larger, and much paler below; *spixii* is mostly shiny black, lower underparts greyer, white wingbars, prominent pale edges on remiges (grey wing panel). Voice. Typical song of both sexes a variable series of 6-9 clear, rich, melancholy, and downslurred whistled notes, "chu chu chu wee" or "chu chuwee chuee", first note higher in pitch, last 2-3 slower, or with 3 slow notes followed by 3-4 shorter, faster, higher notes; also give soft, warbling, sweet-sounding and somewhat variable "teeur, tur-tur-tur-turtutur" song; also accelerated series of whistles that sometimes rises in pitch and becomes weaker; also a more rhythmic and fairly musical "tut-tut-tut-tut-tut-tut" of tittering quality; female has weaker version of typical male song. Voices of birds in NW & E Ecuador said to differ; in E (race *tenebrosus*) a fast but mellow and melodic series, "teu, teu, tu-tu-tu-tu-tu-tu", first notes delivered more slowly and number of "tu" notes varying, in NW (*dorsalis*) tending to have slower delivery which gives different effect, more as "teu, teu, teu, teu, ti-teu, teu" or "teeu, tew-te, teeu".

Habitat. Inhabits borders of humid to semi-arid light or secondary woodland and lowland forest, relatively open areas and clearings with scattered trees, shady plantations, old second growth, riparian and evergreen gallery forest, river islands, sometimes mangrove borders; also in *várzea* second growth. Primarily lowlands to 500 m, but often to 900-1900 m (e.g. around Volcán, in Panama, E slope of Andes, and NW Ecuador); to 2500 m, but rarely above 2000 m, throughout Colombia.

Food and Feeding. Caterpillars, large insects such as beetles (Coleoptera) or leafhoppers (Homoptera), and spiders; also consumes considerable amounts of small berries. Observed singly or in pairs; frequently associates loosely with mixed-species foraging flocks in middle to upper levels of wooded areas, but tends to forage alone where habitat more open or second growth. Typically, perches with rather upright posture. Peers intently, before sally-gleaning (occasionally hover-gleaning) fairly short distances to tree foliage at various heights, from lower middle levels at outer edges of trees to the subcanopy; sometimes comes closer to ground level. Seems to forage in rather lethargic manner most of the time.

Breeding. Apr-Aug in Costa Rica; in Colombia, birds in breeding condition in May-Aug in N and nest-building observed in Mar and mid-Jun in S; nests in Aug-Sept in W Venezuela, Mar-Sept in Trinidad, from Jan in Tobago; Nov-Feb in Argentina. Nest bulky, more or less globular, up to 30 cm high and 25 cm across, entrance hole on side, inner chamber 6-9 cm wide, composed primarily of grass, shredded fibres, thread-like inflorescences, Spanish moss (*Tillandsia*), feathers, dead leaves, various other fibres and moss, lined with grass, bamboo leaves and broad strips of monocot leaves; generally wedged in fork among slender outer branches, but fairly well hidden within foliage, c. 4-38 m above ground, usually high up in large isolated tree. Clutch 2-4 eggs; incubation by female, period c. 18-21 days; chicks fed by both parents, nestling period c. 21 days. Parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded.

Movements. Resident in much of range. Possibly partially migratory in extreme S. Possibly some local migratory movements, as suggested by two males killed by crashing into lighted windows at night at Rancho Grande Biological Station (Aragua), in Venezuela, in Apr.

Status and Conservation. Not globally threatened. Generally considered uncommon to common. Has the largest range of all becards, covering Central America and most of South America; possibly extends farther N, into S Mexico, where unconfirmed reports from E Chiapas. Tolerant of converted and secondary habitats, and occurs in many national parks and other protected areas throughout its range.

Bibliography. Anon. 421. Black-capped Becard

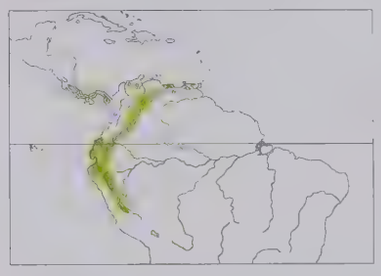
Pachyramphus marginatus

French: Bécarde à calotte noire **German**: Streifenrückenbekarde **Spanish**: Anambé Capirotado

Taxonomy. *T[odus] marginatus* M. H. K. Lichtenstein, 1823, Bahia, Brazil.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to, and possibly conspecific with, *P. albogriseus*; the two appear to replace each other geographically and could be considered to represent a zoogeographical species. Two subspecies recognized.
Subspecies and Distribution.
P. m. nanus Bangs & T. E. Penard, 1921 - SE Colombia (E of Andes, S from S Meta and SE Guainía), S Venezuela (Amazonas, Bolívar), the Guianas, N & W Brazil (E to Maranhão and W Mato Grosso, S to Rondônia), E Ecuador, E Peru and N Bolivia.
P. m. marginatus (M. H. K. Lichtenstein, 1823) - E Brazil (Pernambuco S to NE São Paulo).



Descriptive notes. 13-14 cm; 18 g. Male has crown glossy black with blue sheen and scaly appearance, pale grey supraloral spot, narrow whitish eyering; face pale grey, extending back towards nape; upperparts with variable concentrations of black and grey (some individuals almost uniformly black, some uniformly grey, others with various relative amounts of each colour); rump grey; wings black, white scapulars, two white wingbars, fairly wide white margins on wing-coverts and remiges; tail black, innermost rectrices with small white tips, outer rectrices with broader white tips; throat uniformly pale grey or pale whitish-grey, underparts more or less uniformly pale grey, sometimes whitish-grey lower belly and vent; iris dark; bill mostly dusky or blackish; legs dusky greyish. Differs from *P. albogriseus* mainly in greyer surpaloral, darker underparts. Female has crown rufous-chestnut, greyish supraloral spot, white broken eyering, nape dusky olive, back more uniform olive (sometimes slight rufous tinge near scapulars), rump olive, wings dusky, rufescent or cinnamon-olive scapulars, broad rufous margins on coverts and inner remiges (paler in some individuals), tail dusky with buff-cinnamon tips (especially broad on outer rectrices); pale yellow below, dusky tinge especially prominent on breast. Race *nanus* is considerably smaller. Voice. Typical song a short melancholy series of clear musical notes in variable pattern, "teeu, whee-do-weét", "twee-twee-tee-eet, dear-dear" or "tewtewtewteé, dew-dew", often quickly repeated multiple times, running up scale with last 2 notes lower; often gives a quickly repeated "fleur-de-lis" phrase; also accelerating and trilled series of thin notes with even pitch, e.g. "teeu, tee-tee-tee-te-ti" or "tre-tre'tre-e-e-e-e-it", last note slightly lower; dawn song a soft, delicate, much shorter "tew, tew'tweet" that rises sharply at end.
Habitat. Canopy and interior of humid lowland forest, primarily *terra firme*, and tall second-growth woodland; less often along borders, especially in areas of lighter woodland, where seems to be more or less replaced by *P. polychopterus*. To 1000 m.
Food and Feeding. Insects and fruit. Singly or in pairs; regularly joins mixed-species foraging flocks. Actively peers; flutters or sallies, mostly short distances, to glean items, usually at middle to upper levels.
Breeding. Few specific details. Birds in breeding condition in Apr-May in N Venezuela and upper R Orinoco; gonads enlarged in Sept, SE Peru.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common; probably often overlooked. Much of this species' habitat remains in relatively pristine condition within its large range, and it is considered unlikely to be threatened. Isolated population in E Brazil perhaps at greatest risk. Occurs in many national parks and other protected areas, including Augusto Ruschi Biological Reserve, Intervales and Rio Doce State Parks and Sooretama Biological Reserve, in E Brazil.
Bibliography. Bangs & Penard (1921), Bates & Parker (1998), Butler (1979), Clements & Shany (2001), Cracraft (1985), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1985), McKitrick (1985), Meyer de Schauensee (1982), Naka (2004), Oren & Parker (1997), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schäfer & Phelps (1954), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thiollay & Jullien (1998), Tostain *et al.* (1992), Walther (2004), Willard *et al.* (1991).

422. Black-and-white Becard

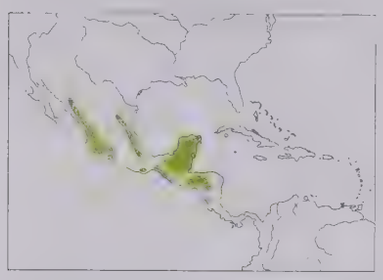
Pachyramphus albogriseus

French: Bécarde pie **German**: Graurückenbekarde **Spanish**: Anambé Blanquinegro

Taxonomy. *Pachyramphus albo-griseus* P. L. Sclater, 1857, "Bogotá", Colombia.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to, and possibly conspecific with, *P. marginatus*; the two appear to replace each other geographically and could be considered to represent a zoogeographical species. Racial identity of birds in NW Ecuador uncertain, as both *guayaquilensis* and *salvini* seem to occur there; some revision of races probably necessary. Five subspecies currently recognized.
Subspecies and Distribution.
P. a. ornatus Cherrie, 1891 - Costa Rica and W Panama (Chiriquí and Veraguas, possibly farther E).
P. a. coronatus Phelps, Sr & Phelps, Jr, 1953 - N Colombia (SW slope of Sierra Nevada de Santa Marta, Sierra de Perijá) and extreme NW Venezuela (Perijá Mts).
P. a. albogriseus P. L. Sclater, 1857 - NE Colombia (E slope of E Andes from N Norte de Santander S to N Boyacá and SE Nariño) and N Venezuela (Andes from Lara S to S Táchira, also Yaracuy and coastal mountains from Carabobo E to W Sucre).
P. a. guayaquilensis J. T. Zimmer, 1936 - W Ecuador (W Esmeraldas and Manabí S, including Puna I, to Guayas and El Oro).
P. a. salvini Richmond, 1899 - E Ecuador (apparently also crossing to Pacific slope in Pichincha) and NW & C Peru (Pacific lowlands S to Lambayeque and Cajamarca, also E side of C Andes from Amazonas and San Martín S to Ayacucho).

Descriptive notes. 13-14·5 cm; 18·5-26 g. Male has glossy black crown with slight bluish sheen, contrasting sharply with almost uniformly plain grey upperparts, pale grey line on nape (sometimes lacking); side of head grey, lores blackish, broad white supraloral stripes connecting narrowly on lower forehead, narrow white broken eyering on pale dusky grey face; wings blackish, broad white margins on secondaries and wing-coverts (one or two wingbars); tail blackish, more dark grey at base, quite broad white tips on rectrices; pale grey below, throat and breast more greyish-white, especially at sides, and belly and vent more whitish; iris dark; bill blue-grey with black tip (variable); legs blue-grey. Distinguished from *P. polychopterus* by white supraloral stripe, grey back with contrasting black cap, lack of white scapulars. Female has prominent chestnut-brown or dull rufous crown with marked broad black margin, white supraloral spots that extend back to form broken eyering, black stripe through eye to hindcrown, pale dusky yellowish-olive face, olive-yellow or pale olive nuchal collar (sometimes lacking), more or less dark olive-green or dusky olive upperparts, olive rump sometimes with faint rufous tinge; wings blackish, broad pale buff or brighter cinnamon margins on secondaries and wing-coverts, very narrow cinnamon edging on leading edge of primaries; tail dusky cinnamon-brown above, darker below, broad cinnamon or buff tips; throat dusky yellow or whitish, breast and sides dusky yellow or pale yellowish-olive, belly and vent pale yellow, sometimes with dusky tinge. Juvenile is similar to female but duller overall, sooty-black edging on crown feathers, less distinct supraloral stripe, more greyish cheeks, no nuchal collar, less distinct cinnamon-buff wing margins. Race *guayaquilensis* is smaller, with very slightly more grey in tail of male; *salvini* male may have whiter belly and vent, female has back somewhat duller, more greyish-olive; *ornatus* has dull flesh-coloured lower mandible; *coronatus* similar to nominate. Voice. Typical song, by male, a fast series of whistled notes, "syoo-syoo-syoo-syoo-syoo-swee", "chew-chewy ch'chewy ch'chewy", or short and melodic warbled "t'you, t'you-duéét", with variations to "chu-chu, chu-é" or "chu-u-ré", usually rising abruptly at end and given at infrequent intervals; typical call a series of variable, high and thin "swee-sweeet" or "weeea-weeeeur" whistles; partners occasionally call back and forth. Voice in Venezuela S to Peru said to be sweet mellow "chu-u-ree", sometimes varied to "cheer, chew-a-weet"; birds from W & E Ecudor said to differ, *guayaquilensis* giving pleasant "tu-tu-dwít" phrase repeated three times in succession with pause between each three-phrase series, *salvini* a more melancholy and longer "twe, twe, tweu, tu-wít" phrase with stronger inflection on final note.
Habitat. Upper levels of understorey and mid-levels of canopy, and interior (occasionally borders) of humid to wet foothill and lower montane forest, tall secondary woodland, humid or deciduous woodland adjacent to primary forest; sometimes dry forest almost to sea-level in W Ecuador and NW Peru. Primarily at mid-elevations, c. 800-2300 m; occasionally lower (especially on Pacific slope) during latter half of year; and locally at 2500-2850 m or as high as 3200 m.
Food and Feeding. Insects and fruit. Singly or in pairs; regularly joins mixed-species flocks. Generally perches calmly, scanning foliage for prey, often turning head into odd positions to peer for insects. Makes short, fluttering, upward sallies, or hover-gleans food items from foliage or twigs at higher levels of canopy.
Breeding. Mar-Apr in Costa Rica. Nest bulky and globular, entrance hole near bottom, composed mostly of dead leaves, with some moss, bits of vines, various plant fibres, etc., generally wedged in vertical fork near tip of trunk or tree branch 7-20 m above ground in subcanopy or forest edge. Clutch size uncertain; incubation by female, period thought to be c. 18-21 days; nestling period probably c. 20-22 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Fairly common in Henri Pittier National Park, in Venezuela, and found also in Cerro Blanco Forest Reserve, Río Palenque Science Centre and Podocarpus National Park, all in Ecuador, and Northwest Peru Biosphere Reserve, in Peru.
Bibliography. Anon. (1998a), Blake (1958), Butler (1979), Clements & Shany (2001), Davies *et al.* (1994), Eisenmann (1955), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Lanyon (1985), McKitrick (1985), Meyer de Schauensee (1982), Phelps & Phelps (1953), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Salaman (1994), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Zimmer (1936b).

423. Grey-collared Becard



Pachyramphus major

French: Bécarde du Mexique **German**: Schwarzrückenbekarde **Spanish**: Anambé Mexicano
Other common names: Mexican Becard

Taxonomy. *Bathmidurus major* Cabanis, 1847, Jalapa, Veracruz, Mexico.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Specimens from Honduras not racially identifiable; tentatively included in *australis*, but could belong with *itzensis*. Five subspecies currently recognized.
Subspcies and Distribution.
P. m. uropygialis Nelson, 1899 - W Mexico (S Sonora S to Guerrero).
P. m. major (Cabanis, 1847) - E Mexico (S Nuevo León and San Luis Potosí S to Oaxaca and W Chiapas).

On following pages: 424. Glossy-backed Becard (*Pachyramphus surinamus*); 425. Rose-throated Becard (*Pachyramphus aglaiae*); 426. Jamaican Becard (*Pachyramphus niger*); 427. One-coloured Becard (*Pachyramphus homochrous*); 428. Pink-throated Becard (*Pachyramphus minor*); 429. Plain Becard (*Pachyramphus validus*).

P. m. itzensis Nelson, 1901 - SE Mexico (Campeche, Yucatán, Quintana Roo).
P. m. matudai A. R. Phillips, 1966 - S Mexico (Pacific slope of Chiapas) and Guatemala.
P. m. australis W. deW. Miller & Griscom, 1925 - Guatemala, El Salvador, Honduras and NC Nicaragua.

Descriptive notes. 14-15·5 cm. Male nominate race has glossy black crown, pale supraloral stripe, pale grey hindcollar; back black or mottled grey and black, rump and uppertail-coverts grey; wings black, white scapular stripe, white margins on wing-coverts, secondaries and tertials; primary P9 shorter and attenuated; tail black, broad white tips on outer rectrices; uniformly light grey below; iris dark; bill blackish, often paler greyish to greyish-flesh on lower mandible; legs dark grey. Female has blackish-brown to glossy blackish crown, pale supraloral stripe, pale cinnamon to tawny-buff hindcollar, cinnamon-brown upperparts, blackish wings (unmodified P9) with cinnamon to cinnamon-brown margins on coverts, secondaries and tertials, tail with broad cinnamon tips and more cinnamon-brown central rectrices (often with black subterminal mark), buff to cinnamon-buff throat and underparts. Juvenile resembles female; quickly acquires immature plumage, male may show some blackish mottling on back, have lemon-buff margins on wings, grey-brown central rectrices with blackish distal marks, whitish tips on outer rectrices, like adult by c. 1 year. Race *uropygialis* male resembles nominate, female has cinnamon-rufous crown, contrasting broad black eyeband, much pales yellowish hindcollar, throat and underparts; *itzensis* male has mostly grey back; *matudai* has buffish-lemon underparts; *australis* slightly smaller than nominate, male rather paler, female darker than nominate female. Voice. Typical song a rich and constantly repeated (usually 4-6 times, and ten in 10 seconds) "hoo wee-deet" or "hu whi-ditt" whistle; also gives more plaintive to clear "peeu peeu" and longer "beeh beeh beeh" series, repeated up to 6-7 times.

Habitat. Humid to semi-arid forest, especially pine (*Pinus*) and oak (*Quercus*), forest edges, plantations. To 2500 m.

Food and Feeding. Insects and fruits. Singly or in pairs; occasionally joins mixed-species flocks. Forages at middle to upper levels.

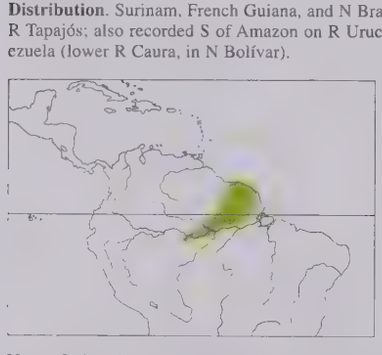
Breeding. Nest with nestlings in Aug, Michoacán; nest was c. 10 m above ground in fork of oak tree (*Quercus*); 35 cm high, 22 cm deep, 23 cm wide; nest roughly globular, with slanting roof; nest built of lichens, twigs and pine needles, roof made of strips of bark held together with silk from butterfly cocoons. Both parents appear to tend and feed fledglings.

Movements. Apparently an altitudinal migrant, at least N of Isthmus of Tehuantepec.

Status and Conservation. Not globally threatened. Uncommon to fairly common, but local. Not well known. Occurs in Insurgente José María Morelos y Pavón National Park (Michoacán), in Mexico, and Lamanai Archaeological Reserve and Río Bravo Conservation and Management Area, both in Belize.

Bibliography. Anon. (1998a), Binford (1989), Brodkorb (1943), Chapman (1896), Contreras (1997), Gelis & Martínez (2000), Howell & Webb (1995a), Hutto (1992), Klaas (1968), Land (1970), Lanyon (1985), McKitrick (1985), Monroe (1968), Paynter (1955), Phillips (1966), Prum *et al.* (2000), Ridgway (1907), Schaldach (1963), Smithe (1966), Storer (1961), Stotz *et al.* (1996), Thurber *et al.* (1987), Watson (1999), Wetmore (1943), Winker *et al.* (1999).

424. **Glossy-backed Becard**



Pachyramphus surinamus

French: Bécarde du Surinam **German**: Weißbauchbekarde **Spanish**: Anambé de Surinam

Taxonomy. [*Muscicapa*] *surinama* Linnaeus, 1766, Surinam.

Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Monotypic.

Distribution. Surinam, French Guiana, and N Brazil (from lower R Negro at Manaus E almost to R Tapajós; also recorded S of Amazon on R Urucu, in C Amazonas); one sight record from Venezuela (lower R Caura, in N Bolívar).

Descriptive notes. 13·2-13·8 cm; 20 g. Male is glossy black above, slight bluish sheen, crown sometimes scaly-looking; some white near bases of scapulars (often concealed); pure white below; iris dark; bill blackish; legs dark. Female has blackish crown feathers broadly tipped dark chestnut-brown (appears chestnut with black spots), pale supraloral line, pale grey nape and upper back, white lower back to rump, blackish wings with fairly broad cinnamon-rufous edging on inner remiges and coverts, blackish tail, outermost rectrices with broad whitish to buffy tips, buffy tinge uppertail-coverts, throat and underparts white. Voice. Soft and sweet-sounding dawn song, usually from semi-concealed perch high in canopy, a series of c. 5-9 notes, "wuweet, weet-weet-weet-weet-weet", repeated at intervals of 5-9 seconds; when foraging, also frequently "kweeé, kew-kew-kew-kew" contact call, somewhat variable, up to 5 "kew" notes; when agitated, also longer series of thin notes faster and trilled towards end, "wee, tee-tee-te-ti'ti'ti'ti'ti'ti'ti".

Habitat. High canopy of emergent trees, subcanopy of tall humid forest, and forest borders, also adjacent clearings and savanna forest; to 300 m.

Food and Feeding. Insects, some fruit. Usually observed in pairs, partners loosely associated. Moves about at rather deliberate pace, peering into thick foliage in high outer canopy of emergent trees or along bare horizontal branches; makes short hops or flights of 0·5-10 m to hover-glean items; rarely, sally-gleans. Appears sometimes to fly long distances to preferred foraging trees; territory thought to be rather large (more than 100 ha).

Breeding. Nests discovered Jul-Oct in Brazil. Nest bulky and globular, entrance hole on side or near bottom, composed of dead leaves, fibres, moss, etc., suspended from drooping branch c. 25-30 m up in tree, usually near nest of wasp or bee (Hymenoptera). No other specific information.

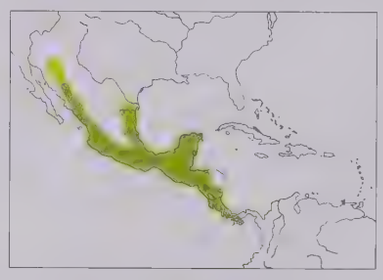
Movements. None known.

Status and Conservation. Not globally threatened. Rare and apparently local. Poorly known; perhaps often overlooked, as it spends most time in canopy. Future range extensions for this species considered likely. Occurs in Jaú National Park and the Ducke Reserve, in Brazil.

Bibliography. Cohn-Haft *et al.* (1997), Cracraft (1985), Forrester (1993), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Lanyon (1985), McKitrick (1985), Meyer de Schauensee (1982), Naka (2004), Oniki & Willis (1982), Prum *et al.* (2000), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Whittaker (1995).

425. **Rose-throated Becard**

Pachyramphus aglaiae



French: Bécarde à gorge rose **German**: Rosenkehlbekarde **Spanish**: Anambé Degollado

Taxonomy. *Pachyrhrynchus Aglaiae* Lafresnaye, 1839, vicinity of Jalapa, Veracruz, Mexico.

Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to *P. homochrous*, *P. minor* and *P. validus*, or even conspecific with first two; all are sometimes combined in a separate genus, *Platypsaris*, differing from present genus in nest shape and placement, as well as in some vocal and minor morphological characters. Racial variation poorly understood; revision clearly necessary. Eight subspecies currently recognized.

Subspecies and Distribution.

P. a. albiventris (Lawrence, 1867) - SW United States (SE Arizona), W Mexico (Sonora and Pacific slope from S Sinaloa S to N Guerrero, also up river valleys E to Chihuahua, Zacatecas and Morelos).
P. a. insularis (Ridgway, 1887) - Tres Marías Is, off W Mexico (Nayarit).
P. a. gravis (van Rossem, 1938) - extreme S USA (S Texas) and coastal region of NE Mexico. (Tamaulipas S to Nuevo León and San Luis Potosí).
P. a. aglaiae (Lafresnaye, 1839) - S Mexico (C & S Guerrero E to S Oaxaca and WC Veracruz).
P. a. sumichrasti (Nelson, 1897) - SE Mexico (C Veracruz S to N & SE Oaxaca, E to Campeche) and W Guatemala.
P. a. yucatanensis (Ridgway 1906) - Yucatán Peninsula.
P. a. hypophaeus (Ridgway, 1891) - Caribbean slope from C Belize and Guatemala S to W Panama.
P. a. latirostris Bonaparte, 1854 - Pacific slope from N El Salvador S to NW Costa Rica.

Descriptive notes. 16·5-18 cm; 33 g. Distinctive. Male nominate race is uniform grey to darker slaty grey above, with contrasting glossy blackish crown and side of head; mostly grey below, with prominent rose-pink lower throat and upper chest; primary P9 shorter and attenuated; iris dark; bill black, lower mandible sometimes paler, blue-grey; legs dark grey or plumbeous. Female has dark slate-grey or brownish-blackish crown with contrasting ochraceous-buff hindcollar, paler lores, tawny-rufous back, brighter rufous wings (normal P9) and tail, ochraceous-buff tinge cheek, neck side, throat and underparts. Juvenile male more or less resembles female but duller above, very faint ochraceous nuchal collar, generally paler below; immature usually has mottled blackish-and-grey upperparts, some pinkish on throat; adult plumage attained by c. 1 year. Race *albiventris* is much paler than nominate, male with paler pink throat, whitish-grey lower underparts, female with pale buff neck, thoat and underparts; *gravis* female has more cinnamon-brown upperparts, buff neck, throat and underparts; *hypophaeus* is much darker, male with more blackish head and upperparts, very dark grey underparts, pinkish area of throat less extensive or entirely lacking, female with sooty-blackish crown contrasting with prominent cinnamon on side of neck, pale lores, narrow buff nuchal collar, deep rufous to rufous-brown upperparts, also with throat and underparts more uniformly ochraceous buff or tawny; *latirostris* is like previous, more blackish-slate above, slate-grey below, darker on breast; *yucatanensis* similar to nominate but has paler underparts; *sumichrasti* much darker than nominate; *insularis* similar to *yucatanensis* but smaller, especially bill. Voice. Commonly heard call a plaintive downslurred "t-sseu", "tzeeu", or shorter "sseeu" or "teew", often changing to rolling chatter or trill, sometimes chattering slurs into plaintive "tcheu" or "tew" calls; variety of strident, high-pitched, and squeaky thin "wheeeiii" or "p'eeeeeii" whitsles often with rising inflection; dawn song a slightly reedy and plaintive "si-tchew wii-chew" or "si-tseeu wii-tzeeu", repeated in various combinations, or longer and more continuous repetition of "wheeuu-whyeeeuur"; also gives quiet "pik" and "pii-dik" alarm close to nest. Perhaps less vocal than most congeners.

Habitat. Various types of forest edge, including pine-oak (*Pinus-Quercus*), canopy of deciduous woodland and evergreen gallery forest and other riparian areas, clearings and open areas with scattered trees, and patches of scrubby second growth. Mostly in lowlands to 300 m, but has been recorded to 2700 m.

Food and Feeding. Insects; also considerable quantities of small fruits and arillate seeds (e.g. *Stemmadenia*). Singly or in pairs, and occasionally with groups of other small birds; often joins mixed-species foraging flocks. Sally-gleans insects and caterpillars by striking foliage, or hawks flying insects; fruits and seeds gleaned.

Breeding. Apr-Jun in Costa Rica. Nest bulky and globular or bell-shaped, up to c. 76 cm long, entrance hole at or near bottom, made from dead leaves, dry vines, grass stems, twigs, various plant fibres, often with bits of *Ceiba* floss or *Inga* flowers worked into the structure, sometimes bits of green vegetation adorning exterior; generally hanging from tip of drooping tree branch c. 4-21 m above ground, often over water. Clutch 3-4 eggs; incubation by female, period c. 18-21 days; chicks fed by both parents, nestling period between c. 20 and 30 days.

Movements. No large-scale movement thought to occur. Populations in N Mexico (N Sonora and Nuevo León) appear to move S during Sept-Feb, perhaps further evidenced by local records in W Panama (including Jan in Santa Clara, and Dec and Feb in Volcán); in addition, observations in Panama of pairs and males without pink on throat suggest smaller-scale movement by more S races (*latirostris* or *hypophaeus*).

Status and Conservation. Not globally threatened. Uncommon to common. Estimated global population 2,000.000 individuals. Status in Panama requires clarification; although conceivably resident, absence of this species in adjacent areas of Costa Rica render this unlikely. Occurs in Río Bravo Conservation and Management Area, Columbia River Forest Reserve and Lamanai Archaeological Reserve, in Belize, and Tarcol Lodge, Carara Biological Reserve and Río Negro Jaguar Reserves, in Costa Rica.

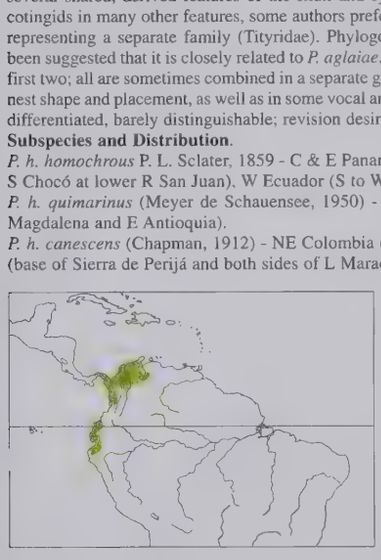
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bent (1942), Binford (1989), Brodkorb (1943), Chapman (1896), Contreras (1997), Dearborn (1907), DeGraaf & Rappole (1995), González-García (1993), Hejl *et al.* (1995), Howell & Webb (1995a), Hutto (1992), Kaufman (1996), Land (1970), Lanyon (1985), Lee Jones (2004), Lowery & Dalquest (1951), McKitrick (1985), Mlodinow & O'Brien (1996), Monroe (1968), Paynter (1955, 1957), Prum *et al.* (2000), Ridgely & Gwynne (1989), Ridgway (1891, 1907), Rowley (1984), Schaldach (1963), Skutch (1969), Slud (1960, 1964, 1980), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Urban (1959), Webster (1963), Wetmore (1943).

426. Jamaican Becard

Pachyramphus niger

French: Bécarde de Jamaïque **German**: Jamaikabekarde **Spanish**: Anambé Jamaicano

Taxonomy. [*Lanius*] *niger* J. F. Gmelin, 1788, Jamaica.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Monotypic.
Distribution. Jamaica.



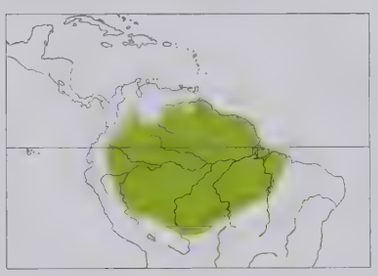
Descriptive notes. 18 cm. Male is entirely black, except for white mark at base of wing (in flight); iris dark; bill black; legs blackish. Female has deep brown crown, reddish-brown upperparts, cinnamon cheek, neck and throat to upper breast, pale grey underparts. Immature is similar to female. Voice. Typical vocalization 2 hoarse "queeck" notes, followed by melodic and syncopated but not well-defined phrase that rises in pitch before falling on last two syllables, and described as sounding like "Co-ome and tell me what you hee-ear".
Habitat. Tall but mostly open forest and edges in hills and mountains; also observed in more closed forest, woodland, pastures with scattered trees, and gardens. Low to middle elevations.
Food and Feeding. Insects and fruit. Moves rather casually beneath canopy, occasionally hovering briefly to glean prey from twigs; also hawks flying insects and sally-gleans food items.
Breeding. Mar-Jun; more than one brood may be raised per season. Nest quite large, bulky and globular, entrance hole near bottom, composed of variety of plant materials, suspended from branch, sometimes above canopy, also lower within woodland or more open areas. Clutch 3 eggs. No other specific details.
Movements. May move to lower elevations when not breeding.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA. Widespread and locally fairly common. About 75% of original forest cover on Jamaica has already been cleared, and remaining forest is largely second growth. Nevertheless, this species survives well in secondary habitats and is tolerant of disturbed habitats.
Bibliography. Anon. (1998a), Bond (1985), Faaborg (1985), Lanyon (1985), McKitrick (1985), Prum *et al.* (2000), Raffaele *et al.* (1998, 2003), Ridgway (1907), Stotz *et al.* (1996).

427. One-coloured Becard

Pachyramphus homochrous

French: Bécarde unicolore **German**: Einfarbbekarde **Spanish**: Anambé Unicolor

Taxonomy. *Pachyramphus homochrous* P. L. Sclater, 1859, Pallatanga, Chimborazo, Ecuador.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to *P. aglaiae*, *P. minor* and *P. validus*, or even conspecific with first two; all are sometimes combined in a separate genus, *Platypsaris*, differing from present genus in nest shape and placement, as well as in some vocal and minor morphological characters. Races weakly differentiated, barely distinguishable; revision desirable. Three subspecies currently recognized.
Subspecies and Distribution.
P. h. homochrous P. L. Sclater, 1859 - C & E Panama, W Colombia (Pacific slope of W Andes S to S Chocó at lower R San Juan), W Ecuador (S to W Loja) and NW Peru (Tumbes, N Piura).
P. h. quimarinus (Meyer de Schauensee, 1950) - NW Colombia (Sinú Valley of Bolívar E to S Magdalena and E Antioquia).
P. h. canescens (Chapman, 1912) - NE Colombia (NE Bolívar, N Magdalena) and NW Venezuela (base of Sierra de Perijá and both sides of L Maracaibo).



Descriptive notes. 16·5 cm; 35 g. Male is mostly dark slaty grey, crown more blackish, rump slightly paler than back; wings and tail, remiges with very narrow, almost indistinguishable, paler margins; grey below, somewhat paler than upperparts, sometimes faint pinkish wash on lower throat or throat sometimes slightly paler grey, sometimes slight dusky tinge on chest and upper belly; iris dark; bill heavy, slightly hooked, blackish; legs dusky. Female is uniformly rufous-chestnut to rufous-tawny above, including crown and tail, often with some dusky feathers around eye area, whitish-cinnamon supraloral, buff-cinnamon face, dusky primaries eged cinnamon, rufous secondaries and wing-coverts with narrow pale cinnamon margins; mostly buffy cinnamon below, more whitish and cinnamon-tinged on throat, more buffy cinnamon on breast and crissum. Juvenile male is similar to female; gradually becomes more black and grey, first on crown and back, lastly on wings and tail. Race *quimarinus* is essentially like nominate; *canescens* may have slightly more whitish below, especially on throat and belly. Voice. Typical song a rather variable, loud, sharp, and sputtering or chattering "stet-ee-ee-teet-tsit-tsit-tsitts-tsít" or "ske-e-et'et'ittt, tseer, tsrip", less clear and not nearly so musical as that of most congeners; also frequently gives squeaky and high-pitched "tweíuuw".
Habitat. Canopy and borders of various types of humid to dry and deciduous forest, adjacent clearings with scattered large trees, secondary and gallery woodland, and disturbed semi-open arid woodland and xeric scrub with scattered tall trees. Mostly below 1000 m, but recorded to c. 1500 m in Ecuador (Chimborazo).
Food and Feeding. Insects and fruit. Usually in pairs, sometimes singly; sometimes joins mixed-species flocks. Forages at mid-levels to subcanopy at forest edges or lighter woodland, sometimes interior. Often nods or pumps the head, much as do *Myiarchus* species; regularly raises crown feathers.
Breeding. No specific information.
Movements. None known.
Status and Conservation. Not globally threatened. Uncommon to common. In Panama, more common in E than in areas farther W. Fairly common, and seen daily, in Northwest Peru Biosphere Reserve, in Peru. Occurs also in Darién National Park, in Panama, and Cerro Blanco Forest Reserve, "Jardin Tropical" (near Esmeraldas), Machalilla National Park, Loma Alta Ecological Reserve and Río Palenque Science Centre, all in Ecuador.
Bibliography. Anon. (1998a), Clements & Shany (2001), Haffer (1975), Butler (1979), Eisenmann (1955), Hilty (2003), Hilty & Brown (1986), Lanyon (1985), McKitrick (1985), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Prum *et al.* (2000), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Sclater & Salvin (1879), Snow, D.W. (1973b), Stotz *et al.* (1996), Walker (2002), Williams & Tobias (1994).

428. Pink-throated Becard

Pachyramphus minor

French: Bécarde de Lesson **German**: Rosensternbekarde **Spanish**: Anambé Gorgirrosa

Taxonomy. *Querula minor* Lesson, 1830, Cayenne, French Guiana.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to *P. aglaiae*, *P. homochrous* and *P. validus*, or even conspecific with first two; all are sometimes combined in a separate genus, *Platypsaris*, differing from present genus in nest shape and placement, as well as in some vocal and minor morphological characters. Monotypic.
Distribution. Most of Amazonia, from SE Colombia (E of Andes, from W Meta and Vaupés S to Amazonas), S & E Venezuela (Amazonas, Bolívar) and the Guianas S to E Ecuador, E Peru, N Bolivia (La Paz, Beni, N Santa Cruz) and S & C Brazil (S to Rondônia, W & N Mato Grosso, N Tocantins, Pará and N Maranhão).

Descriptive notes. 16·5-17 cm; 37 g. Male is more or less uniformly black, face slightly paler greyish-black, except for some white at bend of wing (sometimes hidden); marginally paler below, patch of rosy pink on throat and upper chest (sometimes rather indistinct); iris dark; bill heavy, slightly hooked, blackish; legs dark. Female has crown and nape greyish-brown, buffy supraloral spot, partially grey upperparts that contrast with rufous wings and tail, greyish rump with rufous tinge, throat and underparts uniformly buff. Voice. Relatively quiet compared with most congeners; typical song a clear musical "teeuuuweeet" that is frequently followed by series of twittering notes; also gives clear rising whistle, "tyoooeee"; also soft "pik" or "tic" call notes.
Habitat. Tall humid lowland forest, primarily *terra firme* but occasionally also *várzea*, from mid-storey to subcanopy and borders; to 800 m.
Food and Feeding. Large insects, fruit. Usually observed singly or in pairs, occasionally in small family groups; regularly joins mixed-species foraging flocks. Sluggish; perches upright, frequently bobs its head; typically peers about the vegetation, and changes perch just once to a few times before moving on to different foraging tree. Generally sallies upwards for short distances to the air, but more often to foliage, taking food items in a sally-stall.
Breeding. Nest-building in late Jun and late Aug, in Ecuador. Nest is bulky globular mass suspended from tree, c. 10-20 m above ground; both sexes apparently participate in construction.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Rare to fairly common; perhaps often overlooked. As much of this species' habitat remains in relatively undisturbed condition within its large range, it is not considered to be at any risk. Occurs in many national parks and other protected areas, e.g. Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, Beni and Pilón Lajas Biosphere Reserves and Madidi and Noel Kempff Mercado National Parks, in Bolivia, and Tapajós National Park, in Brazil.

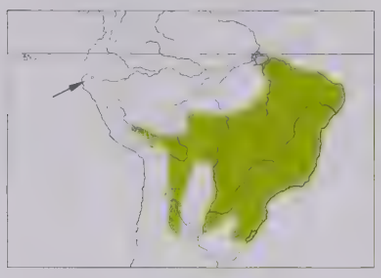
429. Plain Becard

Pachyramphus validus

French: Bécarde huppée **German**: Schopfbekarde **Spanish**: Anambé Grande
Other common names: Crested Becard



Taxonomy. *Lanius validus* M. H. K. Lichtenstein, 1823, Paraguay.
Genus formerly included with *Tityra* in the Cotingidae, but transferred to present family because of several shared, derived features of the skull and syrinx. Because both genera exhibit similarity to cotingids in many other features, some authors prefer to leave them in that family or to treat them as representing a separate family (Tityridae). Phylogenetic affinity of present species unknown. Has been suggested that it is closely related to *P. homochrous*, *P. minor* and *P. aglaiae*; all are sometimes combined in a separate genus, *Platypsaris*, differing from present genus in nest shape

and placement, as well as in some vocal and minor morphological characters. Apparently isolated population discovered in 1998 in SE Ecuador (S Zamora-Chinchipe), more than 1000 km N of previously recorded N limit in S Peru, tentatively included in race *audax*, but may represent an undescribed taxon. Two subspecies currently recognized.

Subspecies and Distribution.

P. v. validus (M. H. K. Lichtenstein, 1823) - E & S Brazil (Marajó I E to Rio Grande do Norte, S to Mato Grosso and Rio Grande do Sul), E Bolivia (Chiquitos), Paraguay and NE Argentina (S to Santa Fe).

P. v. audax (Cabanis, 1873) - extreme SE Ecuador (S Zamora-Chinchipe), SE Peru (both slope of Andes S from Ayacucho and Cuzco), NW, C & S Bolivia (La Paz S to Tarija) and NW Argentina (Saltá, Tucumán, Catamarca, La Rioja, Córdoba).

Descriptive notes. 17-18·5 cm. Male nominate race is very dark greyish to almost black above, with semi-concealed white patch on back; face more greyish, supraloral spot paler smoky grey, some white on scapulars; below, almost entirely uniform pale smoky greyish with prominent cinnamon tinge, throat a bit paler, more whitish-grey; iris dark brown; bill very stout, upper mandible black, lower mandible medium grey; legs dark grey. Female has dark greyish crown contrasting highly with bright rufous nape, upperparts and tail; cinnamon face, duller buff-greyish supraloral spot, wings mostly dusky but with narrow rufous edging on primaries, rufous inner remiges; yellowish-cinnamon throat, dull buffyish-cinnamon underparts. Juvenile presumably resembles female. Race *audax* male is more uniformly greyish below with only slight cinnamon tinge, more greyish-white throat, darker wings; female has dirtier black or sooty crown, slightly darker wings with more dusky inner remiges and coverts, darker underparts. Voice. Not especially vocal compared with most congeners; typical vocalizations comprised of various squeaky or twittering notes; song a low, clear, vibrating, descending series of 6-8 "dui" whistles, second note highest; typical call a shrill "tsree" whistle; calls of nominate said to be fine rising "tsri", "si-i-it" and "tuit".

Habitat. Woodland or montane-forest canopy and borders (especially balsa) and wooded slopes of wet ravines in semi-arid to semi-humid areas. Lowlands to 2000 m, but recorded at 3500 m in Peru (above Urubamba, in Cuzco).

Food and Feeding. Large insects. Usually seen singly, or occasionally among mixed-species flocks. Perches, scanning the vegetation for prey, for c. 3-4 seconds before changing to new perch.

Breeding. Nests found in Nov and Jan in Argentina. Nest bulky and globular, entrance hole on side or near bottom, made from dead leaves, fibres, moss and other vegetable matter, suspended from tip of branch. Clutch 4 eggs. No other information.

Movements. None known.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Rare in Peru, but present in Tambopata-Candamo Reserved Zone. Recent discovery of this species, including an immature male, in Ecuador, in Jan 1998, suggests possibility that range may be more extensive than currently realized; hitherto recorded in this country at only a single locality (Quebrada Honda, in S Zamora-Chinchipe). Elsewhere, occurs in many national parks and other protected areas.

Class AVES

Order PASSERIFORMES

Suborder ACANTHISITTAE

Family ACANTHISITTIDAE (NEW ZEALAND WRENS)

- Tiny to small birds with fine pointed bill, short rounded wings, very short tail, and rather drab plumage.
- 7-10 cm.

- New Zealand.
- Forest (especially of southern beech) and scrub, from sea-level to the tree-line; 1 species in alpine and subalpine areas, including screes and rockfalls.
- 2 genera, 3 species, 6 taxa.
- 1 species threatened, almost certainly extinct; 1 other species extinct since 1600.

Systematics

The New Zealand wrens have a zoological importance out of all proportion to their restricted world distribution and limited diversity, not to mention their faint vocalizations, small size and comparative drabness. Recent studies, involving analysis of DNA, indicate that they are the most "primitive" of the living passerines, in the sense that their ancestors were the earliest to diverge from the main passerine lineage. New Zealand wrens cast light on the evolution and relationships of passerine birds in general, supporting the contention that the passerines had a Gondwanan origin, with an early radiation of forms in the Cretaceous. Superficially, they resemble the "true" wrens (Troglodytidae), but the two groups are not closely related. Indeed, the northern wrens are songbirds, members of the oscine passerines, whereas the New Zealand wrens do not belong in that assemblage.

The anatomical distinctiveness of the New Zealand wrens was first recognized in the early 1880s. Dissections carried out by W. A. Forbes showed that the Rifleman (*Acanthisitta chloris*) and the Bush Wren (*Xenicus longipes*) have the suboscine condition of the syrinx, without intrinsic muscles. About two decades later, at the beginning of the twentieth century, anatomical studies revealed that the ear opening is unusual, being a narrow horizontal slit that opens to a pocket, which extends downwards to the inner ear. Additional distinctive features of the acanthisittids are that the scutellation of the tarsus is unusual, and the form of the inner ear bone, the stapes, is unique. Moreover, New Zealand wrens have only ten rectrices, whereas other passerines have twelve.

Since the 1880s, the New Zealand wrens have usually been placed in a family of their own, Acanthisittidae, created by C. J. Sundevall in 1872; this name has priority over "Xenicidae", coined by Forbes in 1882. For a century, however, there was no agreement as to which groups of New or Old World suboscines were their closest relatives. Furthermore, some research carried out in the 1970s even suggested that the acanthisittids were more closely related to oscines than they were to suboscines.

Studies undertaken in the 1980s, using the DNA-DNA hybridization technique, indicated that the members of this family have no close living relatives, and that they are sufficiently distinctive to warrant their own infraorder, which is a sister-group to all the other suboscine families. The most recent DNA studies appear to be in line with these findings, indicating that the New Zealand wrens are the sister-taxon to all other extant passerines.

The Acanthisittidae are the only survivors of a lineage that was isolated when New Zealand broke away from the ancient southern continent of Gondwana 85-82 million years ago. Thus, they diverged from the other passerines during the Cretaceous. As such, they may be among the oldest living groups of New Zealand endemic birds, older even than the kiwis (Apterygidae). Nevertheless, and in line with New Zealand's very sparse record of terrestrial animals before the Pliocene, there is no fossil record of acanthisittids dating before the Pleistocene. Holocene fossil bones of New Zealand wrens are, however, relatively common in some cave sites, and in deposits accumulated by avian predators.

A summary of the taxonomic history of the family highlights the uncertainty that has surrounded the relationships of these birds. In 1882, Forbes found that the syrinx not only lacked intrinsic muscles, but was also located in the bronchi; because this condition, known as haploophone, exists only in some of the suboscines, he considered that the New Zealand wrens were allied to the New World cotingas (Cotingidae), manakins (Pipridae) and tyrant-flycatchers (Tyrannidae), the Old World pittas (Pittidae) and, possibly, the Madagascan asities (Philepittidae). In reviewing Forbes's study, P. L. Sclater concluded that the Acanthisittidae were closest to the Pittidae, and he placed them between the latter and the broadbills (Eurylaimidae). A year later, in 1893, H. F. Gadow included them between the Pittidae and the Tyrannidae.

Soon thereafter, some confusion arose over the syringeal musculature of the Acanthisittidae. Despite the earlier findings of Forbes, both F. E. Beddard and, in 1905, W. P. Pycraft thought that they had detected an intrinsic syringeal muscle in acanthisittids. Further, Pycraft's anatomical studies led him to conclude that the New Zealand wrens should be placed in a suborder along with tracheophone groups, namely the New World antbirds (Formicariidae), woodcreepers (Dendrocolaptidae), ovenbirds (Furnariidae) and gnateaters (Conopophagidae). He felt that they were more or less closely related to the "synallaxine group" of the Furnariidae, the skull of which was most like that of the Rifleman; in addition, the Rifleman and all of the ovenbirds had schizorhinal nares and the same slender form of the maxillo-palatine processes.

Through much of the twentieth century, the classifications proposed by Forbes and Pycraft were interpreted in varying ways by systematists. The Acanthisittidae have been placed by various authors between the pittas and the Australian scrub-birds (Atrichornithidae), between the pittas and the asities, and as the first family in a superfamily of haploophones that contained also

Like all New Zealand Wrens, the diminutive ***Rifleman*** *is a dinky bird with a very short tail. It is most common in tracts of* Nothofagus *forest, although it will venture into scrublands and gardens where these adjoin native vegetation. It forages like a treecreeper, clinging to trunks and climbing upwards, often in a spiral, until it drops down to the base of the next tree. As it climbs, it hunts the bark for insects, such as beetles, crickets, and caterpillars. In general, the Rifleman forages very actively, constantly flicking its wings and never staying still for more than a moment.*

[*Acanthisitta chloris chloris*, Codfish Island, New Zealand. Photo: Peter Reese/ BBC NPL]

the two last-mentioned families and the New World tyrannoids. This superfamily treatment was put forward by E. Stresemann, in 1934, and a close relationship among its constituent families was recognized by most subsequent authors.

In 1970, C. G. Sibley, in a comparative study of egg-white proteins of passerines, discovered numerous differences between *Acanthisitta* and the New World suboscine groups. He suggested the possibility that the New Zealand wrens were much closer to the oscines, and concluded that a close relationship among the Eurylaimidae, the Acanthisittidae and the Pittidae was highly unlikely. In the following year, P. L. Ames's work on syringeal morphology demonstrated that, contrary to the views of Beddard and Pycraft, published decades earlier, neither *Acanthisitta* nor *Xenicus* possessed intrinsic syringeal muscles. Ames was also of the opinion that the family showed no obvious relationship to any of the New World tyrannoid groups.

Apparent agreement with Sibley came in the mid-1970s, with the publication of A. Feduccia's extensive research work on the passerine stapes. Feduccia came to the conclusion that the acanthisittids were not close to the modern suboscines and that their closest living relatives were among the oscines. He followed this, however, with the iconoclastic proposal that the oscines and suboscines could not have shared a common ancestor, and that the New Zealand wrens were therefore oscines. Although further studies by Feduccia and his team soon led to a retraction of this suggestion regarding passerine phylogeny, Feduccia preferred to retain the Acanthisittidae with the oscines. At the same time, he expressed doubt as to the significance of the stapes in determining avian relationships, while also pointing out that the stapes of *Acanthisitta* differs from that of all other birds.

The initial results of Sibley and colleagues' DNA-DNA hybridization studies, published in 1982, indicated that the New Zealand wrens were the sister-group to the suboscines. Two years later, R. J. Raikow also concluded, from analysis of the hindlimb myology of the New Zealand wrens, that the family was outside the suboscine radiation; he further stated that the syringeal anatomy excluded the acanthisittids from the oscine group.

It is clear, then, that the true relationships of this family have remained uncertain for a very long time. The only point of total agreement seems to be that the New Zealand wrens are the surviving representatives of an ancient lineage of passerines, and that they have no close living relatives. This is the view that was expressed in 1990 by Sibley and J. E. Ahlquist, who stated that the Acanthisittidae are not oscines and who placed them, therefore, in the suborder Tyranni, representing all the suboscines. These authors, however, also mentioned the possibility that the New Zealand wrens should be assigned to a new, monotypic suborder. Very recent molecular-genetic research on the Passeriformes, undertaken by F. K. Barker and co-workers, appears to support that possibility indicating that *Acanthisitta* is the sister to all other passerine birds. In view of all this evidence, herein they have been awarded their own separate suborder, provisionally placed between the suboscines and oscines, roughly in the position where most workers would expect to find them.

In the past, the diversity of the Acanthisittidae was greater than is suggested by the number of its living species. The earlier existence of taxa which have since become extinct shows that the family had radiated into a group of at least seven species, probably after the "Oligocene bottleneck", a time when high sea-levels reduced the land area of New Zealand to about 18% of its present extent. According to current understanding, there are five genera: *Acanthisitta*, *Xenicus*, *Traversia*, *Pachyplichas* and *Dendroscansor*. The last three of these are extinct.

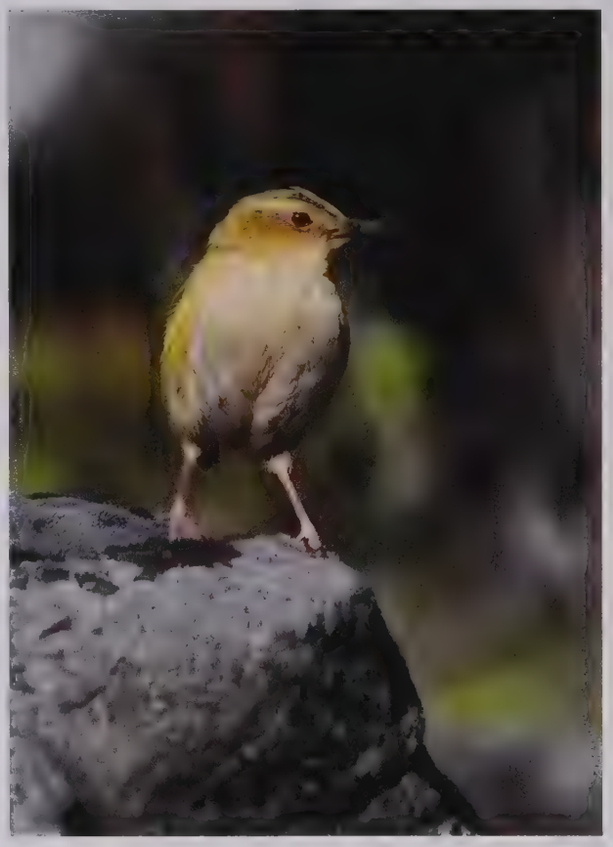
Of the extant genera, one, *Acanthisitta*, contains a single species, the Rifleman. *Xenicus* has just two species, the Bush Wren, which is now almost certainly extinct (see Status and Conservation), and the Near-threatened Rock Wren (*Xenicus gilviventris*). The latter is probably an alpine derivative of the Bush Wren. It has been suggested that the common ancestor of the two species was widely distributed in the forest that covered large areas of New Zealand during much of the Tertiary. The ancestor probably diverged in the early Pleistocene, after the Manawatu Strait divided New Zealand into two major islands. Glacial conditions led the southern population to adapt to a cool climate and an absence of forest. A post-Pleistocene invasion of the southern area by the northern form gave rise to the three subspecies of the Bush Wren that inhabited, respectively, North Island, South Island and Stewart Island, with gene flow being interrupted by new water barriers between the islands in the form of the Cook and Foveaux Straits. Meanwhile, the original, cold-adapted southern form retreated to subalpine habitats at higher elevations, giving rise to the Rock Wren.

Of the three extinct genera, *Traversia* (sometimes merged into *Xenicus*) is represented by the flightless Stephens Wren (*Traversia lyalli*). This species died out soon after its discovery, in 1894, on the tiny Stephens Island, in Cook Strait, between the two main New Zealand islands (see illustration and account in Foreword to Volume 7, pages 45-46). Holocene fossil bones of this species have been found at several sites on both North and

South Islands, demonstrating that the Stephens Island population was a relict of a formerly widespread species.

Three acanthisittid species have been described from fossil bones recovered from Late Pleistocene and Holocene caves and sand-dune deposits. These probably died out following the Maori settlement of New Zealand, which took place in about the year 1250. Two of these extinct species, both described in 1988, by P. R. Millener, were united in the genus *Pachyplichas*; these are the North Island Stout-legged Wren (*Pachyplichas jagmi*) and the slightly larger South Island Stout-legged Wren (*Pachyplichas yaldwyni*). The third, described by Millener and T. H. Worthy in 1991 and representing the last of the three extinct genera, is the Long-billed Wren (*Dendroscansor decurvirostris*), the bones of which have so far been found only in the South Island. This is the only New Zealand wren having a significantly curved beak, and its reduced sternum and wing bones indicate that it was flightless (see Morphological Aspects).

Morphological Aspects



The Acanthisittidae are tiny birds, with a total body length ranging from no more than 7 cm to 10 cm. The diminutive Rifleman is the smallest extant member of the family, weighing as little as 5·5-7 g, with females about 20% heavier than males. Rock Wrens weigh 14-22 g, with an average of about 16 g for males; these figures are probably applicable also to the Bush Wren. The South Island Stout-legged Wren was the largest and most robust of the New Zealand wrens, with an estimated weight of about 50 g. The Long-billed Wren probably weighed about 30 g.

All of the New Zealand wrens for which the plumage coloration is known are predominantly dull green or brown, and all except the Stephens Wren have a prominent pale supercilium. All have short, rounded wings, a greatly reduced tail, and long legs and toes. The bill of the Rifleman is slightly upturned, whereas that of the Rock, Bush and Stephens Wrens is slightly decurved.

Riflemen are markedly sexually dimorphic in plumage. In contrast, Rock Wrens are only slightly so, and the sexes of the Bush Wren are, or were, apparently alike in plumage. In the case of the first two species, the females are rather larger than the males. This is unusual among passerines which show sexual size dimorphism, as the male is usually the heavier in such cases. One study indicated that male and female Riflemen forage together during the non-breeding period, but separately when they are feeding fledglings, at which time energy demands are at their highest. It may be that each sex, by foraging individually, can maximize its feeding efficiency as dictated by the slight morphological differences, which include a longer and more decurved bill and a larger hind claw in the female. The same study also suggested that the green of the male Rifleman may confer good camouflage, given that males with fledglings forage more from foliage than from trunks. Similarly, females favour trunks while foraging alone, and the browner plumage may make them more cryptic at such times.

Adults undergo an annual post-breeding moult that is apparently complete. In the Rifleman, the process lasts 50-60 days, beginning in the last third of January and being completed by April. The primaries are moulted from the inner ones outwards. The adult Rock Wren's moult seems to be of shorter duration, lasting for between five and eight weeks. Little is known about the moult of the juveniles, but it is probable that their first moult is partial, with the flight-feathers and the rectrices being retained.

In the absence of mammalian predators, the first of which reached New Zealand with the Maoris in about 1250, New Zealand wrens were evolving in the direction of flightlessness. Indeed, the Stephens Wren was already flightless, as indicated by its small, rounded wings supported by a reduced wing skeleton, its virtually keel-less sternum, and its somewhat degenerate plumage resembling that of a rail (Rallidae). The only human who described having seen these wrens alive did not report them as flying. The dimensions and proportions of fossil bones of the extinct South Island Stout-legged Wren, North Island Stout-legged Wren and Long-billed Wren suggest that they, too, were flightless. These four species, and an extinct fossil bunting (*Emberiza*) from the Canary Islands, appear to be the world's only flightless passerines.

*The **Rock Wren** is mainly terrestrial. It lives in a harsh upland environment of rocky scree, boulders and low shrubs. It usually forages in pairs, and never joins mixed-species flocks, partly because it is one of the few species that occur in this habitat. It is predominantly insectivorous, catching its prey in low vegetation, in crevices between rocks, or on boulders. In colder months, the diet is supplemented with seeds and berries. However, it is not yet clear whether this species can survive the winter at high altitudes, perhaps by falling torpid when temperatures are low.*

[*Xenicus gilviventris*, South Island, New Zealand. Photo: Don Hadden/ Ardea]

The Rock Wren's long legs are set back on the body, a placement which, combined with the long toes and claws, facilitates the behaviour of scrambling and perching on rocky projections. In the two stout-legged wrens, the relatively reduced wings were countered by robust legs, suggesting that both species spent much time on the ground. The end toe bones are flat, like those of a ground-dwelling bird, rather than curved, like those of a perching bird. As its name suggests, the Long-billed Wren had a long, downcurved bill, as well as relatively short, thin legs, and enlarged anterior neck vertebrae. These skeletal features suggest that it may have behaved in a manner similar to that of the Australasian treecreepers (Climacteridae), moving up and down tree trunks and branches, and over fallen logs, while probing in crevices for food.

Habitat

Apart from the Rock Wren, which is adapted to more open alpine areas, the New Zealand wrens are essentially forest birds. The Rifleman is found in the larger remaining tracts of forest. It is most abundant in southern beech (*Nothofagus*) forest, which covers much of the mountain chain in both main islands and the dry eastern foothills of the South Island, and is less numerous in the mixed podocarp-broadleaf forest that is typical of lower altitudes throughout much of the country. In a study in lowland rimu (*Dacrydium*) forest, it was found that Riflemen prefer to forage in middle and low tiers of the forest, and that they use pole rimu trees, as opposed to mature ones, more than would be expected from the relative abundance of pole trees. In some areas, Riflemen exploit scrub, such as that consisting of the myrtaceous species *Leptospermum* and *Kunzea*, and have adapted to using mature plantations of exotic pines, mainly of *Pinus radiata*. They are occasionally seen in hedgerows, gardens and parks where these adjoin native forest or scrub.

The Bush Wren was found in similar habitats to those occupied by the Rifleman. It lived in beech forest and podocarp-broadleaf forest, mostly at high altitudes, but also occurred in coastal forest and scrub.

The Rock Wren and a large, noisy parrot, the Kea (*Nestor notabilis*), share the distinction of being the only New Zealand high-mountain birds specialized for life in open, rocky alpine

*The **Rifleman** does not invest all its foraging time on tree trunks. It sometimes feeds in the lower canopy or in adjacent shrubs, and it is fond of clinging to the epiphytic vegetation that grows so readily in the humid forests of New Zealand. Here it picks about for insects in the moss, and often enters nooks looking for insect larvae or spiders. The Rifleman is noticeably sexually dimorphic. There is even a theory that this relates to a segregation of foraging niches during the breeding period. Apparently, the green-backed males tend to forage more in leafy or mossy situations, where they are camouflaged, while the brown females forage more on bark.*

[*Acanthisitta chloris chloris*, South Island, New Zealand. Photo: Don Hadden/ Ardea]

and subalpine habitats with herb fields and stunted ground-hugging vegetation. These habitats developed after the onset of the Pleistocene ice ages. In some areas, Rock Wrens live at lower altitudes, in scrub below the bush-line.

Holocene fossil bones of the Stephens Wren have been found at both lowland and high-country sites, implying wide habitat preferences. Similarly, there is evidence that South Island Stout-legged Wrens occurred both in lowland podocarp-broadleaf forest and in subalpine scrub.

As the members of this family appear to be more or less entirely sedentary, they feed, roost and breed in one and the same habitat, throughout the year.

General Habits

The New Zealand wrens are diurnal. The two or three surviving members of the family are all weak fliers. The Rifleman is largely arboreal, and tends to remain close to trees and shrubs. Its flight is short and direct, usually from bush to bush, and often on a descending course. It seldom flies across open ground. Rock Wrens are equally poorly adapted for flight. They rarely cover distances of more than 30 m in a single flight, and rarely fly more than 2-3 m above the terrain.

Since the nominate race of the Bush Wren, which lived on the South Island, was never studied in detail, very little information is available on its general behaviour. For example, it is not known whether it was arboreal in tall forests of that island, or whether it was more terrestrial than the Rifleman. Details of the Bush Wren's life history were, however, recorded on islets near Stewart Island, where the forest in which the subspecies *variabilis* lived was low and the birds spent much time on the forest floor.

The Rock Wren is largely terrestrial, and the Stephens Wren was said to live among rocks and to run about like a mouse. Both the latter species and the three extinct acanthisittids known from Holocene fossils (see Systematics) must have been ground-dwellers to a large degree, since they were all flightless. Nevertheless, they were probably capable to some extent of climbing into trees and shrubs in order to forage among the branches and foliage.

Riflemen move restlessly through the forest and scrub, from tree to tree, seldom remaining in one spot for more than a few seconds. The Rock Wren moves about mainly by hopping, and has a characteristic bobbing action as it pauses between bursts of movement. It never steps or runs but, instead, it progresses across the ground with a bouncing gait, with the feet moving together. This method of locomotion is aided by the broad span of the foot. Both species flick their wings during non-volant locomotion. Rock Wrens also display a bowing movement, which involves leaning forward momentarily.

Bush Wrens were probably similar to Rock Wrens in their locomotion, and they shared the habit of vigorously bobbing the whole body upon alighting.

The territories and pair-bonds of the New Zealand wrens are almost invariably permanent. Adult Riflemen tend to remain in their small home ranges throughout the year. Because pairs occupy exclusive home ranges during the breeding season, they are regarded as territorial, although they do not sing, and territorial fighting or displays are rare. If one partner dies, the other either moves a short distance and sets up a new territory or, perhaps more often, simply waits for a new mate to arrive in its existing territory. From the limited data available, the size of the territory is rather variable. At Dunedin, for example, two territories were about 1·6-2 ha in extent, one of these contracting during the breeding season to 0·8-1·2 ha. In the North Island, however, the average size of territories in the Orongorongo Valley was 6·25 ha in the breeding season and 3·6 ha during the rest of the year.

Similarly, Rock Wrens usually remain paired throughout the year, living in what are said to be territories. These vary greatly in size, the extent being dependent to a large degree on the amount of vegetation present. Smaller territories, those up to about 2 ha in size, contain a very high percentage of vegetation cover, as much as 80%, whereas territories in areas where vegetation is much sparser can extend to 10 ha or more. Territorial disputes between adults are ritualized, with much calling and bobbing from a distance, but little physical contact.

During the incubation and brooding periods, female New Zealand wrens roost in the nest (see Breeding). At other times, both sexes of the Rock Wren sleep at night in a deep hole under rocks, and each pair appears to have several cavities that are used for this purpose. Interestingly, the birds often carry pieces of grass into the roosting hole and construct a special platform on which to rest. They may also retreat to such roost-holes in the daytime in order to avoid strong winds and driving rain. During such adverse weather conditions, they will also seek shelter on protected ledges or against rock faces, where they perch with the plumage ruffled. Riflemen roost either in a sheltered situation in the canopy of a tree, such as a kanuka (*Kunzea ericoides*), or in a suitable cavity in the nesting tree. Here, the birds sit very close together, in physical contact with each other, in order not to lose body heat.

Rock Wrens preen frequently during the day. In addition, the females indulge in regular bathing after egg-laying, when they often stand in a suitable spot in a flowing stream and allow water to shower over them from a small overhang. They also utilize any available puddles which have formed, as, for instance, on the surfaces of large rocks. By contrast, the Rifleman uses wet foliage and dew-sodden grass in which to bathe, primarily during the morning hours. It also performs sunning at times, spreading its wings and fluffing up the body feathers to allow the sun's rays to penetrate. So far as is known, neither species has been recorded as dust-bathing.

Of particular interest is the behaviour of the Rock Wren in its alpine environment during the winter months. In the high-lying rocky habitats in which it lives, the weather at this time of the year can be severe, with prolonged periods of extensive snow cover. One would perhaps expect the birds to descend to lower elevations in order to avoid the harsh and difficult conditions, but this seems not to be the case. During surveys carried out at Lake Harris Basin, from May 1976 to April 1977, the species was recorded only in October and in the months from December to March. Despite intensive searching, no Rock Wrens were seen during May-September and in November, when deep snow covered that subalpine region, nor was any found in April. Somewhat surprisingly, perhaps, the species was not reported from lower elevations, either, and to date there appears to be no evidence that it ever moves down into the tree-line region in adverse weather. If

the Rock Wren does, as seems to be the case, remain in its high-altitude habitat throughout the year, then how does it manage to survive in the severe winter climate? It has been speculated that the birds enter hibernation, and some authors have suggested that they may, at least at night, become torpid or semi-torpid. It is worth noting here that there is a growing list of Australian bird species, including insectivorous passerines, that are now known or suspected to enter a state of torpor as a means of conserving energy, a phenomenon already well documented also for the hummingbirds (Trochilidae) of the Neotropical Region. An alternative possibility, put forward by several other authors, is that the Rock Wrens remain active beneath the snow, where they feed in the pockets of air between the boulders and the shrubs. This is an attractive theory but, despite some statements in the literature, it has not been proven to be true. Indeed, the species' strategy for survival during the hardest months of the year remains unknown.

Voice

The Rifleman and the Rock Wren each have a limited repertoire of simple, short calls and trills. Those of the Rifleman are generally less musical and more rapidly repeated. The calls are very high-pitched, and have been measured at 7-15 kHz for the Rifleman and 8-16 kHz for the Rock Wren. High-pitched calls may carry well under favourable conditions in an alpine environment. In forest and scrub, on the other hand, the Rifleman's voice is usually audible to humans only at very close quarters, and many older people cannot hear the calls at all.

There is no special song as such, but pair-members and members of family groups utter frequent contact calls during foraging. The Rifleman's commonest vocalization is a short, repeated single-note call, transcribed as "zipt", "ssip" or "zee", given constantly by members of a pair while foraging. The Rock Wren's main vocalization is a thin, high-pitched three-note call, "tzee-tzit-tzit", or a short single-note "zipt". Paired individuals, of both species, are said to use antiphonal calling. Both sexes of the Rock Wren appear to give the full repertoire of calls, and the same seems to be true of the Rifleman's main calls.

Little is known of the voice of the probably extinct Bush Wren. A few anecdotal accounts suggest that it had calls that were more powerful than the Rifleman's, but they are still described as faint or subdued.

Food and Feeding

All of the Acanthisittidae are, or are assumed to have been, predominantly insectivorous. Riflemen glean invertebrates from crevices in the bark of trunks and branches, from twigs and leaves of trees and shrubs, and from the epiphytic plants that abound in New Zealand forest. They forage in the manner of treecreepers, moving up and around tree trunks in a spiralling pattern before flying to a low point on another trunk, there beginning another spiralling ascent. They explore fallen logs for food, even entering hollow logs and the cavities between tree roots, but they spend little time on the ground. They can cling upside-down while foraging on the undersides of branches. The principal foods of the Rifleman are small arthropods, especially beetles (Coleoptera), wingless crickets (Orthoptera), spiders, flies (Diptera), moths and caterpillars, and plant-bugs (Hemiptera); small snails and small fruits are occasionally consumed. The species kills arthropod prey by striking them against a firm surface.

Outside the breeding season, Riflemen usually forage in pairs or, more rarely, alone or in family groups of up to eight individuals. Occasionally they join mixed feeding flocks, accompanying such species as Silver-eyes (*Zosterops lateralis*) and Yellowheads (*Mohoua ochrocephala*). A study during the autumn and winter at a site in the South Island showed that, in both seasons, Riflemen foraged for about 80% of the daytime period.

Rock Wrens eat insects, including springtails (Collembola), as well as arachnids and oligochaetes, which they glean from low shrubby or herb-field vegetation, and from crevices between boulders and stones. They use the feet to pry apart vegetation or to grip flexible shoots. They readily enter interstitial spaces while foraging, and at times they disappear down holes for several minutes, and may be heard calling while out of sight. In the winter, when snow covers areas of rocks or scrub, Rock Wrens may be able to move about in gaps and crevices beneath the snow (see General Habits). As well as gleaning prey, this species occasionally catches flying or jumping insects by making aerial sallies, especially in warm weather. Large prey, such as grasshoppers, may be beaten against a hard surface before being swallowed, if necessary after first being dismembered. Interestingly, this acanthisittid has been observed to cache insect food, such as moths, for short periods.

In addition, Rock Wrens supplement their primary diet with seeds and berries of alpine plants, particularly during cooler months, and in some regions they have been seen to drink nectar from the flowers of New Zealand flax (*Phormium*).

Like the Rifleman, the Rock Wren generally forages in pairs. It sometimes feeds in small parties of up to six or eight individuals, presumably family groups, but appears rarely to forage alone. It has not been observed to join mixed-species flocks, but these are less likely to form in the open, subalpine regions which it inhabits.

The Bush Wren is thought to have gleaned food mostly from foliage, and to have been less adept than the Rifleman at exploiting bark crevices on trunks and branches. On islets off Stewart Island, Bush Wrens moved quickly and furtively, feeding on or close to the forest floor. Their known foods were moths, flies and spiders.

Breeding

Detailed information on breeding is available only for the two definitely surviving species of the Acanthisittidae, and there are limited data on the Bush Wren. All three species build bulky enclosed nests in cavities, with access by a side entrance, and lay 2-5 white eggs. In the case of the Rifleman and the Rock Wren, both sexes build the nest, incubate the eggs and feed the young, and the male often feeds the female, especially during egg-laying. The incubation and fledging periods are long. Both sexes of the Bush Wren incubated the eggs and fed the young.

Riflemen are monogamous, and form long-term pair-bonds that endure for several years. They have a protracted breeding season spanning the months of August to January, thus lasting from late winter to late summer. During this period they usually rear two broods of young. Riflemen breed in their first year of life, from the age of nine months. They begin to nest in late winter or early spring, and may build several nests that they never complete. The laying of second clutches begins in early November. They usually nest in holes in the branches or trunks of dead or living trees, or in stumps or logs. Less typical sites are cavities in or on the ground, such as a disused rabbit burrow or the empty skull of a horse, and holes in fence posts and in the walls of wooden huts. They also use artifical nestboxes. The nest itself, which is ovoid or dome-shaped and has a short entrance tunnel 2-3 cm wide, is constructed from twigs, lichen, grass, moss, leaf skeletons and fern roots. The tightly woven nest wall is especially thick early in the breeding season, the purpose presumably being to maximize thermal insulation. The nest-cavity is lined with feathers.

The eggs of this species are laid at intervals of 48 hours, rather than 24 hours. They are relatively large, measuring about 16 × 13 mm, and weigh 1·3 g each, approximately a fifth of the female's body weight. They are incubated for 19-21 days. When an incubating parent leaves the nest, it covers the eggs and blocks the entrance with feathers, an action which helps to prevent heat loss.

In a population of Riflemen studied by G. H. Sherley at Kaikoura, in the north-east of the South Island, courtship-feeding of the female by the male during the egg-laying period represented a major element of her food intake early in the season, but this was not the case with later clutches. This degree of mate-feeding probably allows breeding to begin earlier than would otherwise be possible. First clutches contained an average of 4·4 eggs, compared with 3·8 eggs for second clutches, and the mean incubation period was 19·7 days. The male makes a greater

*The **Rifleman** builds a bulky domed nest in cavities in the branches or trunks of dead or living trees, or in stumps or logs. The nest itself has a short entrance tunnel and is entirely constructed of twigs, lichen, grass, moss, dead leaves and fern roots. Both sexes share the tasks of nest construction and provisioning of young. This photograph shows a female carrying food at the nest entrance, but it is actually the male that provides most items during the 24-day fledging period. This species is essentially monogamous, but a small proportion of the population breeds co-operatively with helpers at the nest.*

[*Acanthisitta chloris*, New Zealand. Photo: M. F. Soper/ ANT/NHPA]

contribution to incubation during the daytime, by sitting for longer periods, than does the female. The female incubates overnight, maintaining the air temperature between the eggs at a level 12-15°C higher than that outside the nest. Males roost away from the nest.

The nestling period of the Rifleman is about 24 days, during which time the chicks grow slowly. On fledging, they are considerably heavier than the adults. After having left the nest, the young remain dependent on the parents for a further 4-6 weeks, and may stay with them in a family group during the non-breeding season. Most juveniles, however, disperse and set up their own territories by the start of winter.

The breeding system of the Rifleman has been studied in some detail at Kaikoura, and with some interesting findings. In the 1980s, a population was colour-ringed and its breeding behaviour observed. It was discovered that some Riflemen nested as simple pairs, whereas others bred co-operatively. Extra adults and juveniles had been reported as attending nests of this species in the 1960s, but this was wrongly interpreted as polygamy. At Kaikoura, observations revealed that such extra birds were, in fact, helpers, and they were present at nests of both first broods and second broods. Those attending first-brood nests were usually unpaired adult males, and these sometimes acquired a mate from the brood which they helped to rear. At second broods, they were more often juveniles from the first brood. The effect of helpers was to reduce the workload of the parental male, which otherwise provides most of the food for the young. Helpers not only fed the nestlings, but also removed faecal sacs and defended the chicks. Even so, they were not allowed by the breeding pair to approach the chicks until the latter were about five days old.

Two types of helper were identified. Those which attended a single nest and contributed a significant amount of the chicks' food, on a daily basis, were regarded as "regular" helpers. These were generally unpaired adult males, at first-brood nests. Individuals which made a lesser contribution to the nesting attempt, visiting less frequently and sometimes not even daily, were categorized as "casual" helpers. The majority of these were first-brood offspring attending their parents' second brood, although some unmated adult males also come into this category. In addition, many casual helpers attend more than one nest. Both types of helper can be present at a single nest, and both continue to feed the young after they fledge.

In the study at Kaikoura, 83 first-brood nests of Riflemen were observed. Helpers were present at 28% of these, over half of which had regular helpers. Of the 50 second broods studied, just over half were attended by helpers, the greater percentage of which were casual. It is worth noting that instances of co-operative breeding are unusual among passerines on a worldwide scale, but are more common among the passerines of the Australasian Region.

Like the Rifleman, the Rock Wren forms monogamous pair-bonds. Unlike that species, however, it has not been observed to breed co-operatively. The members of the pair work closely together to take advantage of the short breeding season that is afforded by the high-altitude climate in which they live. Nest-building commences in mid-September, and the last young leave the nest in early January. In the short breeding season, lasting for less than four months, the pair has time to raise only one brood. With nesting attempts made in the early part of the season, however, a replacement clutch is often laid if the first one fails. An interesting point of difference between the two species

is that not only does the male Rock Wren courtship-feed his mate, but the female also sometimes feeds the male.

The Rock Wren's bulky nest is usually placed in a crevice between rocks, among sturdy roots, or deep in soft clay or mud banks or layers of soft moss. Pairs will excavate nest-holes 10-15 cm deep, removing soil by pecking with the beak and scraping with the feet. The nest, in a chamber at the end of a short tunnel, is spherical or cigar-shaped, with an entrance at the end or the side. The nest walls can be 6-8 cm thick, providing good insulation. Rock Wrens lay clutches of 2-5 eggs, with three being the mode, and, as with the Rifleman, the laying interval is two days. These are incubated for a relatively long period, covering 18-22 days. The young remain in the nest for 21-26 days. As soon as they leave it, they are able to provide almost half of their own food requirements, and within one month they are totally independent.

As both the Rifleman and the Rock Wren are monogamous, forming permanent pair-bonds, and as individuals usually spend their entire lives within a single restricted area, they have little need for any complex breeding displays. As the egg-laying period approaches, the male Rifleman normally spends most of his time in close proximity to his mate, perhaps as a means of preventing extra-pair copulations. On the other hand, there are several observations of a male, during the laying period, leaving his partner's side and moving away, even when a neighbouring male was very close by. Further, although breeding adults are often aggressive towards helpers in the early stages, they soon accept the presence of these additional birds. In the case of the Rock Wren, the female, which selects the nest-site, performs bobbing and wing-flicking movements as she presents nest material to her mate. She continues to demonstrate her chosen site by wing-spreading and wing-vibrating, with much calling.

Very little is known about the breeding biology of the Bush Wren. From the few data available, it appears that this species nested in November and December. The nominate race, which inhabited the South Island, usually nested in a hole in a tree trunk or branch, in the fork of a double trunk, or among the roots of a fallen tree. The Stewart Island subspecies, *variabilis*, which occurred also on smaller islands to the south-west, often nested low down; its nests were located in holes in the ground, on fallen logs or in clumps of ground-ferns. The few clutches found consisted of two eggs; some statements in the literature refer to occasional clutches of three eggs, but it seems that such claims have never been substantiated. Nests with eggs were found on Solomon Island, off Stewart Island, in November and December. Although it is known that the two sexes of the Bush Wren shared incubation and brood-feeding duties, the incubation and nestling periods of the species were never determined.

Movements

New Zealand's endemic passerines, once they attain breeding age, are mostly sedentary throughout the year. They engage in little or no latitudinal or altitudinal movements in relation to the seasons. In line with this, colour-ringing studies of Riflemen in the north-east region of the South Island, at Kaikoura, revealed that the species remained on its territories in all months of the year. In a 21-ha study plot, however, there was some evidence, from seasonal changes in population density, that a small number of individuals possibly undertook local movements into or out of the study area. At another locality, in the north-west of the South Island, counts made at different times of the year indicated the possibility that some Riflemen descended to lower altitudes in September, in order to breed. A similar possibility was suggested by observations on Stewart Island. Whether or not this species does perform short, seasonal altitudinal movements, however, remains open to question.

Rock Wrens living in subalpine habitats are thought to remain there in all seasons, including the austral winter. So far as is known, there are no records of the species at lower elevations during the non-breeding season, even when weather conditions at higher levels are very harsh. It has been suggested that, after heavy snowfall, Rock Wrens survive by remaining active in the air spaces between the buried rocks and plants, or by entering a state of torpor for short periods (see General Habits). Although one or other, or even both, of these theories may be correct, there appears as yet to be no firm evidence for either of them.

Juveniles appear to disperse only short distances. Studies of Riflemen indicate that the young usually move from the natal territory to the nearest suitable area of forest. In one case, five subadults crossed 300 m or more of pastureland containing small patches of remnant forest. At two study sites, one of 12 ha and the other of about 80 ha, seven immature Riflemen dispersed outside the boundaries of the respective sites.

Relationship with Man

Riflemen are much-loved among birdwatchers for their diminutive size. They are the smallest New Zealand birds. In turn, the species' smallness, drabness, quietness, and confinement to forest and scrub mean that it is not widely known to the general public. Nevertheless, there are several reports of Riflemen visiting campsites and becoming quite tame, even picking up food scraps and taking grease and fat from pans and plates.

The Maori name for the Rifleman, *Titipounamu*, refers to its dark green coloration, *pounamu* being the name for the beautiful jade-like nephrite that the Maoris fashioned into clubs and ornaments. Similarly, the species' English vernacular name is believed by some authors to have possibly arisen from the similarity of the male's green plumage to the greenish colour of the tunics worn by the New Zealand First Infantry Regiment. An alternative theory is that its high-pitched, piercing calls reminded people of the sound of whistling bullets.

There appears to be no widely used Maori name for the Rock Wren, presumably because the original Maori settlers spent little time in the cool subalpine areas where the bird lives. For the same reason, few contemporary New Zealanders have ever seen this bird. Nevertheless, the species has had some influence on human thinking in the South Island, where Zit Creek and Zit Saddle, both in Westland, are named after the Rock Wren's "zipt" call.

On the South Island, the Bush Wren was called *Matuhi* by the Maoris, and there is a Maori saying that, if you kill this bird, snow will fall.

Status and Conservation

Of the seven species of New Zealand wren, three are known only from Holocene fossil bones (see Systematics). They appear to have become extinct during the period between Maori and European settlements of New Zealand, in the years between about 1250 and 1769, as a result of the ecological disruption caused by the earlier colonists. In particular, habitat clearance and the introduction of a species of south-east Asian rat, *Rattus exulans*, would have had a devastating effect on the wildlife of the islands.

Since European settlement, a period which has seen massive deforestation, the draining of swamps and the introduction of further predatory mammals, the Stephens Wren too has died out, as almost certainly has the Bush Wren. The Stephens Wren appears to have been both discovered and, soon thereafter, eliminated by a pet cat. The interval between its initial discovery and its extinction is probably the shortest for any animal species. Late in 1894, one of the Stephens Island lighthouse-keepers, D. Lyall, retrieved from the cat about 17 specimens of the wren, a dozen of which are still available in museum collections. Lyall twice saw the bird alive, and was seemingly the only European ever to have done so. It should be noted, however, that some regard this as an apocryphal tale, suggesting that deliberate collecting for museums was a major factor in the bird's demise.

The Bush Wren once occurred throughout New Zealand. The North Island subspecies, *stokesii*, was so rare in historical times that it is represented in museums by only three specimens, two collected in the Rimutaka Range, near Wellington, in about 1850 and one from Taupo, in the central part of the North Island. Subfossil bones reveal that it was formerly more widely distributed in the North Island, so that it was presumably already in

Three flightless species of New Zealand wren presumably died out some time after Maori settlement, whereas the Stephens Wren (Traversia lyalli) *and the Bush Wren* (Xenicus longipes) *were still extant in the early days of the European colonization. They were apparently driven to extinction by introduced predators, the last probable Bush Wren sighting being in 1968. Of the two definitely surviving species, the* ***Rock Wren*** *is considered Near-threatened. In this case, too, the main threat is posed by introduced predators, particularly the stoat* (Mustela erminea).

[*Xenicus gilviventris*, Homer Saddle, Fiordland National Park, South Island, New Zealand. Photo: Geoff Moon/FLPA]

decline as a result of Maori settlement. Two individuals were seen near Wellington in 1918, and the last reasonably reliable sightings were made near Lake Waikaremoana, in the eastern part of the island, in 1949 and 1955. The South Island race of the Bush Wren was widespread, especially in mountain forest, at the time when Europeans first arrived in New Zealand. Before long, however, the effects of this colonization must have begun to reduce the wren's population, and throughout the nineteenth century this subspecies almost certainly declined in all parts of its range. The last probable sightings in the South Island were in Southland, in 1947, and in the Nelson Lakes National Park, in the northern region, in 1968.

Slightly more isolated in the south, on Stewart Island and its associated satellites, the subspecies *variabilis* survived for a little longer. This race, sometimes referred to as "Stead's Bush Wren", was studied in the 1930s on islands off the south-west coast of Stewart Island. There were possible sightings of Bush Wrens on Stewart Island itself in 1950 and 1951, but by the 1960s the species had become confined to just one islet with the name of Big South Cape Island. Tragically, an invasion of black rats (*Rattus rattus*) began on Big South Cape in 1962, the rats having apparently reached the island by climbing along the mooring lines of fishing boats. As the rat's numbers increased, the island's wildlife declined rapidly. Before the wrens disappeared, in 1965, the New Zealand Wildlife Service, the forerunner of the present-day Department of Conservation, transferred six individuals to nearby Kaimohu Island, which was rat-free. Two wrens were seen on Kaimohu in 1972, but an inspection in 1977, and subsequent visits by ornithologists, revealed none. The Bush Wren has now "officially" been listed as extinct by BirdLife International, so, sadly, hope of its rediscovery must realistically be abandoned.

The demise of the Bush Wren represents the most recent extinction among New Zealand birds. The magnitude of the ecological disaster on Big South Cape Island was not fully appreciated at the time. Along with the Bush Wren were lost the last populations of the Stewart Island subspecies *iredalei* of the Subantarctic Snipe (*Coenocorypha aucklandica*) and of a species of mammal, the greater short-tailed bat (*Mystacina robusta*).

So far as the two surviving members of the Acanthisittidae are concerned, the Rock Wren is currently considered to be Near-threatened, while the Rifleman is not believed to be at any risk. The Rock Wren's preference for high altitudes means that it has suffered relatively little from habitat clearance, and predation by introduced mammals may also be less intense in subalpine areas than at lower altitudes. Nevertheless, introduced mammalian predators remain the principal threat to the species, which is rendered vulnerable by its largely terrestrial habits and weak flight (see General Habits) and by the fact that it nests in cavities in or near the ground (see Breeding). In particular, the stoat (*Mustela erminea*) is known to kill and eat Rock Wrens, and even house mice (*Mus musculus*) have been reported as killing the birds. There are no estimates of the current population of the Rock Wren. Although it is reported as being relatively common in some areas, it may have declined in others. Latest reports suggest a major decline at a site in the north-west of its range as a result of predation by stoats.

The best-known member of the family is the Rifleman. This species is fairly widespread in native forest habitats in both of New Zealand's main islands, and it has been frequently reported from the northern part of Stewart Island. In the late 1800s and early 1900s, its range contracted wherever lowland forest and scrub were cleared. Since then, however, its spread into exotic pine (*Pinus*) forests is welcome evidence of a degree of adaptability to man-modified habitats. The Rifleman remains reasonably common. Recorded densities of this species include, for example, 9-15 breeding pairs in 6 ha of forest and ten individuals in just 1 ha. The only potential threats come from the removal of native forest for agriculture, or the replacement of such forest by commercial plantations of exotic trees, and from predation by introduced mammals. Fortunately, the conversion of native forest to exotics is no longer permitted on government land, and this damaging activity is therefore far less widespread than it once was.

Genus *ACANTHISITTA* Lafresnaye, 1842

1. Rifleman

Acanthisitta chloris

French: Xénique grimpeur **German**: Grünschlupfer **Spanish**: Acantisita Verdoso
Other common names: Alpine Rifleman, Rifleman Wren; North Island Rifleman (*granti*); South Island Rifleman (*chloris*)

Taxonomy. *Sitta chloris* Sparrman, 1787, "Cape of Good Hope"; error = Queen Charlotte Sound, South Island, New Zealand.
Morphological differences between races minor and poorly understood; further study needed. Supposedly larger, more yellowish birds in SW of range (Fiordland) described as race *citrina*, but considered indistinguishable from nominate. Two subspecies recognized.
Subspecies and Distribution.
A. c. granti Mathews & Iredale, 1913 - North I and outliers, New Zealand.
A. c. chloris (Sparrman, 1787) - South I, Stewart I and outliers.

Descriptive notes. 7-9 cm; male c. 6 g, female 7 g. Tiny greenish passerine with short rounded wings, very short tail, pale supercilium, and fine, slightly upturned bill. Male is bright green above, rump yellow-green; folded wing shows patches of green, black and white, with transverse yellow band at base of flight-feathers (pale wingbar obvious in flight); tail dark, tip whitish; chin, breast and belly white, variably washed cream or light yellowish, flanks yellowish; bill dark brown or black, some with yellower gape and base of lower mandible; legs dark brown or yellow-orange, soles yellow. Female is duller than male, green of upperparts replaced by yellow-brown with darker streaks, rump yellow-brown. Juvenile resembles female, but streaked on breast as well as upperparts, supercilium less distinct, some individuals heavily and extensively spotted and streaked. Race *granti* is supposedly less yellow below, including flanks, but variable. Voice. Calls simple, mostly faint, sharp and high-pitched; main call a squeaky repetitive "zipt".
Habitat. Forest, especially beech (*Nothofagus*) forest, and scrub; also pine (*Pinus*) plantations, especially older ones with dense understorey of native shrubs. Sometimes found in remnant patches of native vegetation in otherwise cleared areas; in open areas recorded also in hedgerows, in patches of introduced gorse (*Ulex*) and broom (*Cytisus*), and in roadside vegetation. Occasionally visits gardens and urban parks. Mainly in uplands, to c. 1550 m.
Food and Feeding. Predominantly insectivorous. Diet includes wide variety of small arthropods, especially coleopterans, including weevils (Curculionidae), and wingless crickets (Orthoptera), spiders, flies (Diptera), moths and caterpillars, and plant-bugs (Hemiptera); small snails occasionally consumed, and small berries occasionally eaten. Reported as picking up food scraps around camps. Kills larger arthropod prey by striking them against a firm surface. Forages in pairs or in small groups, rarely singly; occasionally joins mixed-species flocks with e.g. Silver-eyes (*Zosterops lateralis*). Gleans invertebrates from trunks, branches, twigs and leaves, spending little time on ground. Restless forager along trunks and branches; wings constantly flicked. Flight usually short and direct between trees and shrubs.
Breeding. Season Aug-Feb; 2 broods. Monogamous; long-term pair-bond. Often breeds co-operatively, with helpers; helpers at first brood usually unpaired adult males, at second brood usually offspring of first brood. Nest built by both sexes, ovoid or dome-shaped, side entrance with short tunnel, of sticks, grass, leaf skeletons and rootlets, occasionally some moss, dead leaves, wood chips or spider webs, chamber lined with feathers, placed in cavity in tree trunk, branch, fence post or similar site, occasionally in ground; nestbox often used. Clutch 2-5 eggs, laid at intervals of 48 hours; incubation by both sexes, period 19-21 days; chicks fed by both parents, from fifth day also to varying extent by helpers; nestling period 21-27 days, mostly 24-25 days; young independent by 4-6 weeks. In one study of 14 nests, 57·4% of eggs hatched and 48·9% fledged; in another study, mean of 3·9 young fledged at first-brood nests with helpers and 3·7 at those without helpers, corresponding figures for second broods being 3·4 and 3·3; nests sometimes preyed on by mammals, e.g. stoats (*Mustela erminea*). First breeding at 9 months. In study of colour-ringed population, two males lived for 6 years, average longevity of adult males 2 years 2 months, of females 1 year 8 months.
Movements. Resident. Probably sedentary; possibly some short local movement, possibly also a degree of altitudinal movement, but confirmation required. Juveniles disperse short distances.

Status and Conservation. Not globally threatened. Locally common in suitable habitats. Recorded densities include 2·2-3·4 birds/ha and 9-15 breeding pairs in 6 ha. Declines noted in some areas, mainly in North I, in 19th and 20th centuries. Clearance of native forest for agriculture and for planting of exotic trees, especially pines, has adverse effect on populations; conversely, has adapted to pine habitat in some areas. Sometimes killed by stoats and domestic cats, and one observation of an adult caught by Sacred Kingfisher (*Todiramphus sanctus*).

Bibliography. Genus *XENICUS* G. R. Gray, 1855

2. Bush Wren

Xenicus longipes

French: Xénique des buissons **German**: Waldschlüpfer **Spanish**: Acantisita de Matorral
Other common names: Green Wren; North Island Bush Wren (*stokesii*); South Island Bush Wren (*longipes*); Stewart Island/Stead's Bush Wren (*variabilis*)

Taxonomy. *Motacilla longipes* J. F. Gmelin, 1789, Dusky Sound, South Island, New Zealand.
Race *stokesii* known only from three museum skins and few sightings. Race that formerly occupied Stewart I uncertain, assumed to be *variabilis*, which described from offshore islets. Three subspecies recognized.

Subspecies and Distribution.
X. l. stokesii G. R. Gray, 1862 - North I, New Zealand.
X. l. longipes (J. F. Gmelin, 1789) - South I.
X. l. variabilis Stead, 1936 - Stewart I and outliers.

Descriptive notes. 9-10 cm; 16 g. Small greenish passerine with rounded wings, very short tail, pale supercilium, long legs and fine bill. Nominate race somewhat variable, has top of head dark brown to olive-brown, with white supercilium; upperparts variably dull olive-brown or greenish, black carpal patch, remiges edged yellowish, tail olive; upper throat whitish, underparts brownish-grey, flanks yellowish; bill brownish-black; legs slaty black, feet pale brown. Sexes alike. Juvenile poorly known, apparently like dull-plumaged adult but with fine pale streaks above, paler underparts. Race *stokesii* is poorly known, apparently more bluish on neck side and chest, bright yellow patch on flanks; *variabilis* is browner than nominate, variable, supercilium duller and less distinct. Voice. Little known; faint trills and rasping calls.

Habitat. Beech (*Nothofagus*) forest, podocarp-broadleaf forest, and coastal forest and scrub. Mostly at high altitudes.

Food and Feeding. Very poorly known; predominantly insectivorous, taking wide variety of small arthropods, mostly coleopterans. Invertebrates gleaned mainly from foliage and branches, also by probing in bark crevices and epiphytes. Often forages on or close to forest floor, searching leaf litter, mosses and lichens; bobs after alighting on ground.

Breeding. Almost unknown. Laying Nov-Dec. Nest a ball of fern leaves and rootlets, lined with feathers, one nest of nominate race pouch-shaped; placed in cavity, often near ground, sometimes in tree fork. Clutch 2 eggs, possibly sometimes 3; incubation and brood-feeding by both sexes, periods not known.

Movements. Sedentary.

Status and Conservation. Almost certainly EXTINCT. Formerly occurred throughout New Zealand, but declined following human settlement and the introduction of terrestrial predators. North I race *stokesii* last seen in 1955, near L Waikaremoana; in historical times was very rare, and only three specimens exist in museum collections. Nominate race in South I was once common, but populations declined rapidly after Europeans arrived; by 1950s had become extremely rare, and last sighting was in Jan 1968, when two individuals were observed in Nelson Lakes National Park, in N of island. Race *variabilis* was common on Stewart I and, especially, its satellite islands in 1930s, but was last recorded on Stewart I in 1950, with a possible sighting in 1951; by 1960s persisted only on offshore islet of Big South Cape I, where still common in 1961, but arrival on island of black rats (*Rattus rattus*) in following year led to rapid reduction in the wren population, with last confirmed record in Aug 1964. Meanwhile, six birds had been translocated from Big South Cape I to nearby Kaimohu I, where no rats were present; two were seen on Kaimohu in 1967 and 1972, but none was found in 1977 or on subsequent visits. The chances that any individuals still survive are exceedingly remote, and in 2000, the species was declared extinct by BirdLife International. The principal reason for its demise was evidently the introduction of alien predators; clearance of native forest may also have had an adverse effect, particularly in the earlier years.

3. Rock Wren

Xenicus gilviventris

French: Xénique des rochers **German**: Felsschlüpfer **Spanish**: Acantisita Roquero
Other common names: South Island Wren; Fiordland Rock Wren ("*rineyi*")

Taxonomy. *Xenicus gilviventris* Pelzeln, 1867, mountains of South Island, New Zealand.
Plumage appears to vary clinally, males becoming brighter from N to S; supposedly smaller, more greenish birds in S (Fiordland) described as race *rineyi*, but now considered only a bright morph. Monotypic.

Distribution. Mountain areas of South I, New Zealand.

Descriptive notes. c. 9·5 cm; male 16 g, female 20 g. Small passerine with rounded wings, very short tail, pale supercilium and fine bill; legs and toes long, feet almost half length of body, claws (especially hind claw) long. Male has head and neck dull olive-brown, white supercilium bordered above and below by narrow black stripes, upperparts and wings olive-green, prominent black patch at bend of folded wing, tail dull olive-brown (head and upperside brighter, greener, in S of range); throat whitish, rest of underparts pale grey-brown to creamy or off-white, flanks yellowish (richer yellow in S); bill blackish-brown; feet pale brown. Female is duller and browner above, often duller below. Juvenile differs from adult in having mostly dark grey bill with orange base of lower mandible, darker legs and feet. Voice. Small repertoire of simple calls, high-pitched and penetrating; main calls a 3-note "tzee-tzit-tzit" and short single "zipt", less frequently repeated than in *Acanthisitta*.

Habitat. Low shrubs, open scree and rockfalls in alpine and subalpine habitats; often in areas with prolonged snow cover. Often near water source, e.g. stream. At 1200-2900 m, usually to 2400 m, i.e. above timber-line; also lower, down to c. 900 m, in subalpine scrub in Fiordland.

Food and Feeding. Predominantly insectivorous. Takes wide variety of small arthropods, e.g. coleopterans, orthopterans, dipterans, springtails (Collembola), spiders, centipedes (Chilopoda), millipedes (Diplopoda), oligochaetes. Occasionally consumes small seeds and berries; also seen to drink nectar from flowers of New Zealand flax (*Phormium*). Large prey may be beaten against a hard surface, and if necessary dismembered, before being swallowed. Observed to cache insect food for short periods. Forages mostly in pairs or in small groups of 4-8 birds, sometimes singly. Terrestrial and arboreal. Hops and runs frequently; flies only short distances, bobs vigorously up and down, often with wing-flicking, on alighting. Gleans items from low vegetation, and from crevices between boulders and stones; readily enters interstitial spaces, and disappears down holes for several minutes; possibly forages beneath snow in austral winter. Occasionally makes aerial sallies after flying or jumping insects. In study in Mt Cook National Park (Fiordland), covering Dec-May, gleaning was commonest technique throughout period; aerial sallying most frequent in Dec-Jan, and most fruit-eating observed in Jan-Mar.

Breeding. Season Sept-Jan. Monogamous; long-term pair-bond. Nest built by both sexes, cigar-shaped or spherical, tiny entrance hole at end or side, mostly of grass with some soft twigs, leaves, bark, fern scales and hair, chamber lined with feathers, sometimes also with soft moss and lichens; placed in cavity in or near ground, e.g. in crevice between rocks, among sturdy roots, or deep in soft clay or mud bank or layer of soft moss. Clutch 2-5 eggs, laid at 2-day intervals; incubation by both sexes, period 18-22 days; both also feed chicks, nestling period 21-26 days; young independent at 2-3 weeks. Of total of 106 eggs in one study, 91 (c. 86%) hatched and 71 (67%) produced fledglings; nests preyed on by stoats (*Mustela erminea*) and house mice (*Mus musculus*).

Movements. Resident. Apparently sedentary; no evidence for suggested movement to lower elevations during severe weather.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in South Island of New Zealand EBA. Has rather fragmented distribution, from NW Nelson S to Fiordland, but uncommon, even in suitable areas. Former presence in North I indicated by Holocene fossil bones. Rare in N of range in Nelson and W Marlborough, but believed to have been more common in the past in Nelson; more widespread and perhaps locally fairly common farther S in Southern Alps. Principal threat is introduced mammalian predators, especially stoat (*Mustela erminea*) but also house mouse (*Mus musculus*); possible that former take a fairly high percentage of nestlings, as well as some adults, and probably many eggs taken by mice.

Class AVES

Order PASSERIFORMES

Suborder MENURAE

Family ATRICHORNITHIDAE (SCRUB-BIRDS)

- Small, largely terrestrial, highly secretive birds with short, rounded wings, broad and rather long tail often carried cocked, long and strong legs with well-muscled thighs.
- 17-23 cm.

- South-west and eastern Australia.
- Dense undergrowth in scrub, thicket and forest.
- 1 genus, 2 species, 3 taxa.
- 1 species threatened; none extinct since 1600.

Systematics

The scrub-birds are generally placed in their own family, the Atrichornithidae, but they have at times been treated as a subfamily of the lyrebirds (Menuridae) of eastern Australia, with which they share some characteristics. The scrub-birds have, in fact, been grouped with the lyrebirds since the first anatomical studies were carried out on nineteenth-century specimens. A. H. Garrod's findings, which were published in a number of papers in the 1870s, revealed that both the lyrebirds and the scrub-birds have only three pairs of intrinsic syringeal muscles, rather than the 5-9 pairs possessed by other oscine songbirds, although the scrub-birds also have a few fibres of a fourth pair; on the other hand, these muscles are attached to the end of the bronchial semi-rings, the typical oscine condition. He concluded that the lyrebirds and the scrub-birds were closely associated, and he placed them next to the oscines, a treatment adopted by all subsequent authors for a century or so. During this period, the two groups were together treated as distinct from all other passerines and were given various taxonomic rankings, most notably that of a separate suborder (Menurae) positioned between the suboscines and oscines, as herein. Contrary to this view, in the 1970s on the basis of the unmodified stapes it was proposed that they should perhaps be considered true oscines, a conclusion also supported by molecular-genetic studies.

Extensive research in the 1970s and later, including numerous studies on a single specimen of the Noisy Scrub-bird (*Atrichornis clamosus*), supported the contention that lyrebirds and scrub-birds are, indeed, each other's closest relatives. As well as having similar syringeal muscles, they have been shown to share similarities in body pterylosis and in the musculature of the fore and hind limbs. The two families do, however, differ in wing and tail pterylosis, as well as in details of the natal down and plumage development; further, the DNA-DNA hybridization distances between them are fairly large. Their relationships with other Australian passerine families, however, are less clear. DNA-DNA hybridization studies and protein electrophoresis agree on the proximity of Atrichornithidae and Menuridae, but give conflicting results on the proposed relatedness of both to the Australasian treecreepers (Climacteridae) and the bowerbirds (Ptilonorynchidae). The DNA work also suggests that the scrub-birds have been separated from the lyrebirds since the Eocene. They are likely, therefore, to be part of an ancient radiation of the earliest songbirds in Australia.

Fossil remains of Noisy Scrub-birds have been found in caves in the south-west of Western Australia, in deposits dated at 3000-6000 years old. The number of scrub-bird remains at this site suggests that the birds were plentiful at that time.

Morphological Aspects

Scrub-birds are small, semi-flightless, ground-dwelling birds living in dense undergrowth in scrub and rainforest habitats. Their short, rounded wings are unsuitable for true flight. They have a greatly reduced sternum, somewhat poorly developed breast muscles and rudimentary clavicles (furcula), all of which reflect their poor flying abilities. The feathers are soft and pliant and, except for the primaries, tend to lack the interlocking hooks of most bird feathers. As a consequence, they do not zip together but are quite open, giving the feathers a loose appearance, another indicator of poor flying abilities. On the lower back, especially, the feathers are surprisingly long.

The sexes are distinct. The male Noisy Scrub-bird is the largest member of the family and measures 12-13 cm from the tip of the bill to the base of the tail, the latter adding a further 10 cm. It weighs between 50 g and 60 g, with a mean of 52 g. By contrast, the female weighs about 34 g. The male Rufous Scrub-bird (*Atrichornis rufescens*) approaches the size of the female Noisy Scrub-bird.

Similarly, the plumage differs between the sexes. The males have a distinctive black area on the throat and upper chest, this being bordered by prominent white malar stripes. On the male Rufous Scrub-bird this dark area is extensive. On the Noisy Scrub-bird it is narrower and more obviously transverse, and the contrasting white chin area and malar stripes are larger. The dark throat patch is, in fact, created by white-tipped black or dark grey feathers. When the head is pointed downwards, the overlapping pale tips may disguise the dark band of the Noisy Scrub-bird. When he throws his head back to sing, however, the dark feather bases are exposed and the throatband is emphasized. The white tips wear away as the season progresses, and this can make the dark area more prominent. In the male Rufous Scrub-bird, the dark throat patch, although more extensive than that of its congener, is less clearly outlined because it is surrounded by brown feathers. Neither of the female scrub-birds has a dark throat patch.

When an individual is observed in the wild, the throat coloration is not always apparent and the males of both species generally appear to be small brown birds. This is especially true when a rapidly moving scrub-bird is merely glimpsed in the low light

conditions typical of the dense habitat occupied by the two members of this family. At close quarters, however, it can be seen that the feathers of the upper body are finely vermiculated with irregular dark bands, and adults of both sexes exhibit a rufous area around the vent. These features are particularly noticeable on the Noisy Scrub-bird.

Both species have a broad and rather long tail, with rounded feather tips, and this is often carried cocked. The legs are long, with well-muscled thighs, and the birds have surprising strength. The bill is bicoloured, the upper mandible being of a dark ash-grey and contrasting with the pale fleshy pink of the lower mandible, which curves downwards at the gape. A small narrow ridge on the upper mandible extends into the feathers of the head and ends in a small hump. This structural feature may be useful in protecting the feathers when the scrub-bird feeds among leaf litter, as both species often use the head to lift and turn over leaves in order to reveal prey (see Food and Feeding).

Juvenile plumage consists of chestnut-brown feathers on the head, nape, upper back, wings and underparts. The lower back, tail and vent area are dark grey. In its first summer, the juvenile moults into a pre-basic adult plumage. This is similar to that of the adult, but, in the case of males, is less strongly marked.

Only few details are available on the moult of this family. The adult Rufous Scrub-bird undergoes a complete moult after breeding, although the precise timing of this is uncertain. One specimen was in active primary moult in October and another in December; active moult of the tail feathers has been recorded in August and October, and that of the body in December. The primaries are replaced from the inner ones outwards. The adult Noisy Scrub-bird is likely to have a similar strategy, its post-breeding moult probably taking place during the austral summer, although individuals with incomplete moult have been trapped in June in some years.

Soon after fledging, the young undergo a partial moult in which most of the body feathers are replaced, with the larger upperwing-coverts, the remiges and the rectrices being retained. In captivity, two female Noisy Scrub-birds completed this partial moult in 49 and 55 days, respectively, while one male required 79 days.

Habitat

The two species of scrub-bird live on opposite sides of the Australian landmass, each inhabiting dense vegetation. Within its tiny global range in the south of Western Australia, the Noisy Scrub-bird occupies moisture-gaining sites in scrub, thicket and low forest. It favours low forest in deep gulleys at near-coastal sites in the Two Peoples Bay area, east of Albany, but it also occurs in densely vegetated patches of tall shrubs on the hillsides and in forest formations along watercourses. The Rufous Scrub-bird, restricted to the eastern side of Australia, lives among dense understorey vegetation of subtropical and temperate rainforest. It also occurs on the edges of eucalypt (*Eucalyptus*) forest abutting rainforest where there is a rainforest understorey, and it occupies sites along watercourses, on ridges and around treefalls.

Dense vegetation provides essential protection for the semi-flightless scrub-birds. Both species also require plentiful leaf litter, debris and rotting wood, which offer habitat for the invertebrate fauna on which the birds feed (see Food and Feeding). Nests of Noisy Scrub-birds are placed in clumps of sedges or piles of debris, often near the centre line of a gulley or the edge of a small stream. Those of Rufous Scrub-birds are built in similar situations. Good scrub-bird habitat, therefore, usually contains a mosaic of dense vegetation at about 1 m above the ground, small open patches of dense leaf litter with a rich invertebrate fauna, and areas with clumps of sedges suitable for nesting.

In Western Australia, the vegetation in Noisy Scrub-bird habitat may be fire-prone and wildfire can occur at frequent intervals. In moister areas, the scrub-birds will sometimes move into a burnt area within a few years, but periods of at least ten years between fires are required in order to allow the development of the appropriate combination of dense cover and invertebrate fauna to support numbers of breeding birds. The optimal post-fire age of the vegetation for scrub-birds is not known. Studies have demonstrated, however, that Noisy Scrub-birds continue to do well in areas on Mount Gardner, in the Two Peoples Bay region, which have not been burnt for more than 50 years, and farther east, on Bald Island, the species lives and breeds in habitat last burnt more than 100 years ago.

*The **Rufous Scrub-bird** is typical of the Atrichornithidae in being small, with non-descript brown plumage, short, rounded wings, and a long graduated tail. Each rectrix is rounded, as can be seen here, and the tail is often held cocked. These morphological features, especially the weakness of the wings, are linked to a sedentary lifestyle and terrestrial habits; both species in the family rarely fly more than a couple of metres downslope. The bulging ridge at the base of the culmen is another characteristic feature, possibly associated with their habit of flicking over leaves and twigs while foraging.*

[*Atrichornis rufescens*, Australia. Photo: E. McNamara/Ardea]

General Habits

Scrub-birds are difficult to observe in the field, and studies of their behaviour are often not practical. Visibility is low in the dense vegetation, and the birds rarely reveal themselves. When they do, they do not remain in view for long. The low light levels and the birds' cryptic coloration and behaviour can frustrate all but the most patient of birdwatchers. Nevertheless, scrub-birds are highly inquisitive and will often approach an observer, usually keeping out of sight while moving rapidly around the watcher, sometimes while singing. The loud, far-reaching territorial song of the male (see Voice) is the most obvious characteristic and the best means of detecting the bird. Males spend a good deal of time singing, especially during the breeding season, and holders of long-term territories sing throughout the year, although at a much-reduced level during the summer months. Female scrub-birds, on the other hand, do not sing, and they are, therefore, even more difficult to locate than are males.

Not surprisingly, both members of the family are sedentary and territorial. Their short, rounded wings render them incapable of efficient flight. They do, however, use their wings to assist in leaping and scurrying about in the vegetation, sometimes making fluttering downward "flights" of a metre or two. They also use the tail and the powerful legs to achieve very rapid acceleration. Although basically terrestrial, scrub-birds are also good climbers, and they can rapidly ascend shrubs and trees by squirrelling up trunks and along branches. When feeding, they generally move methodically around an area, mostly keeping within cover, but occasionally venturing into small open patches where the leaf litter may be thicker. When agitated, however, they are capable of moving through dense vegetation surprisingly quickly, sometimes making use of ground-level runways created by small marsupials such as quokkas (*Setonix brachyurus*) and quendas (*Isoodon obesulus*).

Male scrub-birds defend territories throughout the year, and over successive years. Territories of male Noisy Scrub-birds can be up to 5 ha or more in extent, although the core area where the male spends most of his time is generally smaller, at around 1 ha. The territories are generally well dispersed in the landscape but tend to be concentrated along gulleys, where they appear to be linear, matching the riparian vegetation. Even in good habitat, the centres of neighbouring territories are often 200-300 m apart. During the course of the day, the male moves slowly around the core area of his territory, feeding and singing as he progresses. During the breeding season he will often interact vocally with other males.

Territories can persist for long periods. At Mount Gardner, for example, some Noisy Scrub-bird territories have been occupied continuously for more than thirty years, although the occupants have undoubtedly changed during this period. The experimental capture and removal of a territorial male will usually result in its replacement by another male, sometimes within a few hours. This suggests that there could be rapid turnover in territory occupancy. Indeed, radio-tracking of Noisy Scrub-birds at Two Peoples Bay and at reintroduction sites (see Status and Conservation) has shown that ownership of territories can change several times within a few days.

Although the behaviour of the Rufous Scrub-bird is poorly known, it seems to be similar to that of its congener. Males of this species are said to defend territories of 5-10 ha, although the average size of male territories in one study was only 1·17 ha. As with the Noisy Scrub-bird, the males spend most of their time in a core area which is somewhat smaller in extent. Females apparently occupy home ranges which partly overlap the territory of the male. During the breeding season their home ranges appear to be centred on the nest-site, which they also defend from other females.

Some males, of both species, defend territories for only a short period of time, varying from a few days to about three months. These are in suboptimal areas, with insufficient habitat suitable for breeding, but generally adequate to satisfy the bird's feeding requirements for the period of occupancy, which is usually the length of the breeding season. The occupants of such territories are presumed to be non-breeding immatures.

When resting during the daytime, scrub-birds perch in shrubs and small trees, on logs and fallen branches, or on rocks or ground debris, up to 60 cm above the ground. The Rufous Scrub-bird has also been seen to perch on the side of a rough-barked tree. At night, males normally roost outside the core area, often on the edge of the territory. The Rufous Scrub-bird prefers sites close to the ground, and on one occasion an individual was observed as it slept low down on the small limb of a fallen pine (*Pinus*). Male Noisy Scrub-birds make use of a number of roost-sites, which are generally at or near the tops of shrubs or small trees. Captive individuals of this species have been observed to move up to the tops of shrubs 2 m tall as darkness falls.

Visual displays and postures are seldom observed, and their functions are uncertain. One display has been described for the male Noisy Scrub-bird. An individual, perched about 1 m up on the branch of a shrub, lowered his wings, fanned his tail, and then brought the tail forwards until it was almost parallel to his back, whereupon he rapidly quivered the whole body and tail while uttering the loud territorial song. Although this posture, which is reminiscent of a well-known display of the lyrebirds, has not, it seems, been observed by other ornithologists, body-quivering while singing is common. A so-called "rodent-run display", performed by the female, appears to be restricted to the vicinity of the nest (see Breeding). When running on the ground, scrub-birds often carry the tail cocked, with the body in a crouched posture and the head and neck extended, but it is uncertain just how many details of this behaviour are related to alarm reaction.

There appears to be no documented information on the maintenance behaviour of the two species. One would expect bathing, at least, to be a fairly common practice, but no information exists for wild-living individuals. Even in captivity, when water in a small dish has been continuously available, Noisy Scrub-birds have never been seen to use this for bathing. Captives of this species have, however, been recorded as preening occasionally.

Voice

In contrast to their skulking and elusive behaviour, the male scrub-birds are remarkably conspicuous vocally. The loud territorial song of the male, almost deafening when heard at close quarters, is given frequently. That of the Rufous Scrub-bird is relatively simple, consisting of a series of repeated strident "chip" or "cheerp" notes which gain in intensity to reach a crescendo. Bouts of singing last for about ten minutes, but can extend to twice that length of time. The male Noisy Scrub-bird's territorial song also consists of a succession of strident notes, usually rising in pitch and developing into a cascade of pealing notes, before ending abruptly. The notes are sometimes on a descending scale, but the song is always loud and penetrating. Indeed, it is from the very loud song of the male that the Noisy Scrub-bird acquired both its English and its scientific names. This song carries well and can be heard up to 1·5 km away.

During the breeding season, territorial males sing at intervals throughout the day, most actively early in the morning and late in the afternoon. The singing of one territorial male often appears to elicit song from neighbouring males, and the ensuing song "contest" may engage several territorial males within earshot of the first male. Where there is a high density of scrub-bird territories, these engagements can result in almost continuous song during the day. Noisy Scrub-birds will also sing at night, especially when moonlight brightens the habitat.

Both territorial and non-territorial males of the Noisy Scrub-bird produce another song, This is known as "short song", because it is usually, but not always, of shorter duration than is the territorial song. The short song is also loud and resonant, but is not so directional as territorial song, and its structure differs, being more like a continuous outpouring of notes of similar intensity; sonagram analysis has suggested that some mimicry of other species is occasionally incorporated, but this is certainly not noticeable to the human ear. This song is often used during interactions between males, and between males and females, and is probably less assertive than the territorial song. Males also use a single-note call or a combination of two or three notes, and alarm calls.

*As demonstrated by this **Noisy Scrub-bird**, terrestrial habits beget strong legs and sturdy feet. The other feature associated with partial flightlessness is that the barbs of the body feathers are not hooked together by barbules. This leads to the obvious fluffy or downy effect visible in this photograph. Of the two members of the family, this is the larger bird, with duller brown plumage and a more conspicuous rufous vent. Both species have a pale lower half to the bill, contrasting with a darker upper mandible.*

[*Atrichornis clamosus*, Two Peoples Bay Nature Reserve, Albany, Australia. Photo: Jiri Lochman/ Lochman Transparencies]

Female Noisy Scrub-birds do not sing, but use a sharp alarm call and a soft contact call. When agitated, particularly when disturbed at the nest, a female will often produce a series of high-pitched squeaks while moving rapidly around the nest-site (see also Breeding).

Unlike that of its congener, the male Rufous Scrub-bird's repertoire includes a wide variety of mimicry of other bird species, although such mimicry appears not to be common. It also contains loud scolding "churr" notes and a single ringing note. Females of this species are far less vocal than are the males, but they do sometimes engage in song duets with the male. In these duets, the female's song is a softer but more complex version of the male's territorial song. Females also utter ticking calls and high squeaks, mostly when tending nestlings, and chattering notes when feeding a fledgling.

Food and Feeding

Scrub-birds forage for invertebrates in leaf litter on the ground, in decaying wood, and among the stems and leaves of understorey plants. They poke the bill into crevices in wood and insert it beneath leaves, sometimes lifting the leaves with the bill and head and then lowering them back into place. At other times they use the head to shovel under the leaves. The Rufous Scrub-bird, in particular, is noted for its habit of burrowing through deep leaf litter in this manner, a characteristic that has earned it the colloquial name of "Mouse bird". It then scratches at the ground in order to reveal prey items. The Noisy Scrub-bird relies more on flushing prey from the litter and other debris.

The diet of the Rufous Scrub-bird is not well known. Beetles, scrub-snails (*Helix*) and snail eggs are recorded as being taken by this species, which is also thought to consume some plant seeds. More information is available on the foods eaten by the Noisy Scrub-bird. These include invertebrates of a wide variety of orders, but studies at Two Peoples Bay indicate a preference for ants (Formicidae), beetles, spiders and crickets (Orthoptera). An old report refers to seeds having been found in the stomach of one adult, but these are a most unlikely item for a species that, as modern studies and all observations indicate, has a diet restricted to live food. It is possible that the items identified as such were, in fact, the head capsules of ants, which can look very like seeds. Nestling Noisy Scrub-birds also receive a wide range of invertebrates, with 18 orders recorded. The females bring relatively large items, mainly spiders and crickets, with which to feed their young in the nest; in addition, they sometimes feed the chicks with small amphibians and reptiles, and there are records of the myobatrachian *Crinia georgiana*, skinks (Scincidae) and the gecko *Phyllodactylus marmoratus* being delivered to nestlings.

Song output is maintained at a high level during the breeding season, and the energy for this activity requires large quantities of food. In captivity, scrub-birds will often eat half of their own body weight in food each day.

Breeding

Some male Noisy Scrub-birds occupy territories which they defend or advertise with loud song throughout the year, whereas others sing mainly during the breeding season. Song intensity increases from April, usually when the opening rains come to south-west Western Australia. It continues at a high level through June and July and decreases through August and September, dropping off rapidly in October. This singing activity defines the breeding season. In the case of the Rufous Scrub-bird, singing is at a peak between September and January, and these times appear to mark the limits of the breeding season of the species.

It has been stated that Noisy Scrub-birds are monogamous, but long-term observations do not support this. Indeed, it is probable that the males are polygynous. Males are seldom seen with females, and the only roles which they play in the reproduction process are those of defending the territory and mating. A few observations suggest that the female seeks out the singing male at mating time, but males also appear to be ready to mate or, at least, to interact with any female. Nests are almost always on the outskirts of male territories, and often midway between two territories, and occasionally two active nests are found within a few metres of each other. In fact, much of the breeding behaviour of the territorial males can be likened to that associated with an exploded-lek system.

Although they are often difficult to see, scrub-birds are easily heard. The voice of the ***Rufous Scrub-bird*** *is the simpler: a series of strident "cheerp" notes that gains intensity until a vibrant crescendo. This song is so loud that it is almost deafening from close range and liable to leave a ringing in the ears. In the breeding season it is given at intervals through the day, and regularly on moonlit nights. The female does not generally sing, but she can produce a softer, more complex version of the male song, sometimes joining him in a duet.*

[*Atrichornis rufescens rufescens*, Lamington National Park, Queensland, Australia. Photo: Roger Brown/ Auscape]

Female scrub-birds build their nests without any help from the male. The female Noisy Scrub-bird tends to build in the same area in successive years, often within 5 m of her previous nest if that was successful; if disturbed, she will usually construct a new nest about 50 m away. The Noisy Scrub-bird's nest is typically built at about 80 cm from the ground, or lower, and is well hidden in a clump of sedges (*Lepidosperma*, *Gahnia*) or, sometimes, in a dense shrub or a pile of debris. That of the Rufous Scrub-bird is generally placed very low down, usually about 15 cm from the ground, in a clump of *Gahnia* or *Carex* sedges, in a grass tussock or in a small tree-fern.

The nest of both species is a domed structure with a side entrance and is constructed from long, pliant leaves of sedges and grasses. That of the Rufous Scrub-bird consists mainly of *Gahnia*, *Carex* and *Xerotes*, sometimes with some leaves or pieces of dead tree-fern incorporated, whereas the Noisy Scrub-bird's nest is built mostly from *Lepidosperma* and *Anarthria* and, less commonly, *Gahnia*, *Agonis* and *Dryandra*. The inner layers of the Noisy Scrub-bird's nest are quite tightly bound, but the outer layers are looser. The whole structure is typically about 18 cm high, 12·5 cm wide and 14 cm deep, and the walls are up to 5 cm thick. There is often a small "hood" above the entrance and usually a runway, which may be 20 cm long, sloping up to the opening. The runway is made by loosely weaving the leaves of the substrate. The bottom part of the nest-chamber can be 5 cm thick. The nest of the Rufous Scrub-bird is similar but slightly smaller, and the entire interior is lined with a cardboard-like material made of wood fibre, which provides a smooth, dry surface. The Noisy Scrub-bird lines only the bottom half of the nest in this way. No feathers or other material are used as lining.

Female Noisy Scrub-birds generally begin nest-building in May, and the majority of the single-egg clutches are laid in the latter half of June. Occasionally, the egg is laid earlier. If an egg is preyed on, the female will rebuild in a different location and lay again, which can result in eggs being incubated late in the season. From the few comparable details which exist for the Rufous Scrub-bird, it appears that this species lays in September or October and that the clutch consists probably of two eggs.

The eggs of the Atrichornithidae are oval in shape. They are slightly glossy, and have a very pale buff to pinkish-white ground colour irregularly marked with brownish-red to dark purple-brown spots, speckles and blotches, which are concentrated at the larger end. The eggs of the Rufous Scrub-bird measure about 22·9 × 17·5 mm on average, while those of the Noisy Scrub-bird are somewhat bigger, with dimensions of about 28·5 × 19·8 mm.

The incubation period of the Noisy Scrub-bird is generally five to six weeks, which is rather long for a small passerine. Incubation by this species takes place in the coldest part of the year, when ambient daytime temperatures in a deep, shaded gulley may be below 12°C. The female leaves the nest at intervals during the day in order to feed, and is sometimes absent for several hours. Despite the thick insulation provided by the nest, the female's absence results in cooling of the egg, a factor which would contribute to the lengthy period of incubation. In observations of individuals in captivity, in Perth, where food was provided and the ambient winter temperatures were higher, shorter incubation periods of 30 days were found to be common. The incubation period of the Rufous Scrub-bird is not known, but it is believed to be similar to that of its congener.

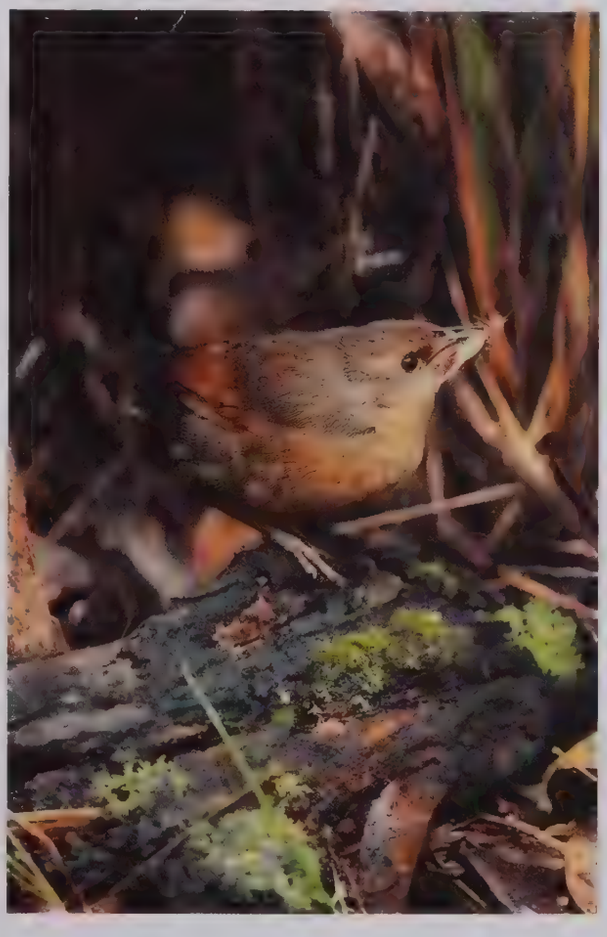
On hatching, the chick has a covering of long downy feathers on the upper parts of the body. It is fed by the female. No information on the care of the chick and subsequent aspects of reproduction is available for the Rufous scrub-bird. The following details, therefore, apply to the Noisy-Scrub-bird, but it seems likely that some, at least, would be applicable to both species. In the initial stages, the female broods the chick after each feed; daytime brooding ceases after about ten days, but the female continues to brood her young at night until the nestling fledges. She removes faecal sacs directly from the cloaca of the nestling, which presents its posterior to the female as soon as she arrives at the nest. The female deposits the faecal sacs under a shrub or in a pool in a nearby stream. As the chick grows, it may be fed relatively large food items, including small frogs, geckos and skinks (see also Food and Feeding). The young scrub-bird leaves the nest at three to four weeks, but it takes a surprisingly long period to reach independence. Indeed, it may remain in the company of its mother for three to six months after fledging.

The female is always agitated by the presence of an intruder near the nest, and in these circumstances she keeps a very close watch on the unwanted visitor. On leaving the nest containing a chick, the female has been reported to make fast circuits of the nest-site for up to 20 minutes, calling noisily, and occasionally

performing a running display in which the body is held low, with the head and neck parallel to the ground and the wings spread, with the outer wing trailing. Although this behaviour has been termed the "rodent-run display", it should be pointed out that such a display has not been corroborated by others in many decades. Indeed, the description of it equates to the normal nest-defence behaviour of a female when disturbed at the nest.

Little is known about chick survival or fledging success. In some Noisy Scrub-bird populations, however, survival rates may be as high as 90%. It is thought that the mardo (*Antechinus flavipes*) may prey on this species' nests, but this has not been documented for certain. This small marsupial carnivore is probably capable of taking an egg, at least from an unoccupied nest, but it is active at night, when the female scrub-bird is present and would probably defend the nest vigorously. Nevertheless, mardos do take up residence in old nests. It is possible that southern bush-rats (*Rattus fuscipes*) also take nest contents, but there is no evidence for this. Nest predation by snakes, on the other hand, seems less likely, since these reptiles are generally inactive during the main nesting time of the Noisy Scrub-bird.

Female Noisy Scrub-birds are capable of breeding in their first year, while males may take two or more years to reach sexual maturity. Males are usually two years old before they begin to sing, and they may not become fully mature until their third year.



Movements

Scrub-birds are generally sedentary. They do not make any regular seasonal movements, their short, rounded wings and other morphological features (see Morphological Aspects) rendering them incapable of sustained flight. Males defend long-term territories within which the core area (see General Habits) remains constant from year to year, and females build their nests in the same area each year (see Breeding).

The young appear to stay in or near their natal territory for some years before acquiring their own territory. This can be either the natal territory or another one nearby. Dispersal farther afield may be uncommon, as subadult males are often found in or near an existing, occupied territory. A few male Noisy Scrub-birds, however, are known to have dispersed up to 10 km from the nearest breeding areas, and the actual distance travelled "on the ground" may, of course, be much greater. Moreover, an immature Rufous Scrub-bird, when it was mist-netted at Pappinbarra, in New South Wales, had travelled at least 20 km from the nearest suitable breeding habitat, although dispersal over such distances is likely to occur only occasionally.

Dispersal can enable scrub-bird populations to expand and to occupy new areas of habitat. For example, new territories and new subpopulations of Noisy Scrub-birds have been discovered about 3 km from known existing populations, presumably as a result of adult or subadult individuals dispersing away from the natal territories. In addition, territory-holding adult males, when translocated and then released, are capable of moving distances of up to 3 km to a new site.

Continuous dense cover is required to facilitate dispersal. Although a scrub-bird will move across small roads having a clearway of 5-6 m, it approaches these areas very cautiously; when it does decide to cross, it does so at speed and immediately dives into cover on the other side. Scrub-birds do not traverse larger cleared areas such as farm paddocks, bare dunes, or country cleared of understorey vegetation by a recent fire.

Noisy Scrub-birds *scurry and ferret about in undergrowth and leaf litter. They insert their bills into holes in decaying wood, flip dead leaves with their bills and even tunnel under deep piles of twigs and leaves. They are searching for a variety of prey types, both insect and non-insect, including ants, beetles, spiders and crickets. Although arthropods make up most of the diet, some small vertebrates, including tiny frogs, skinks and geckos, are captured in the breeding season and fed to nestlings. Early reports of seeds in the diet are thought to be erroneous, and both species of scrub-bird seem always to eat live food.*

Relationship with Man

Because of their secretive and elusive nature, the scrub-birds are little known to humans in general. Even ornithologists have hitherto been unable to uncover many of the secrets of these birds' lives, and many aspects of their biology and ecology remain to be elucidated. A colloquial name for the Rufous Scrub-bird is "Mysterybird", which seems highly appropriate in vew of the paucity of data on this species. Another of its names, incidentally, is "Mouse bird", alluding to its habit of burrowing through leaf litter on the ground (see Food and Feeding).

In 1842, J. Gilbert discovered the Noisy Scrub-bird near Mount William, in the hills south of Perth, but it was not found again in this area. The bird was, however, well known to the Noongar people of the King George Sound area, on the south coast of Western Australia, who referred to it as "Jeemuluk", and Gilbert found the bird to be reasonably common at the sound in 1843. By the end of the nineteenth century, however, Noisy Scrub-birds were no longer common and even dedicated ornithologists could not locate the bird in known habitats (see Status and Conservation). In 1948, near the original discovery site, a memorial was raised to Gilbert and the "sweet-voiced bird of the bush".

Although the male scrub-bird sometimes gives away his presence by the rustling sound that he makes when moving through the vegetation, it is usually his deafeningly loud song (see Voice) that is the sole means by which a human observer is made aware of an individual bird's presence. It is hardly surprising, therefore, that, so far as is known, it is only this striking vocalization that has had any influence on the human populations which live in the areas of Australia occupied by the two scrub-birds. Indeed, Gilbert's original field notes on the Noisy Scrub-bird refer to the ear-ringing sensation produced by the bird's song when heard at close quarters. J. Gould received the specimens and used Gilbert's notes as the basis for the scientific name *clamosus*, meaning noisy or very loud. The song can, in fact, be quite musical; it is not really "noisy", but it is certainly loud.

Because of its history of apparent extinction followed by "rediscovery" (see Status and Conservation), the Noisy Scrub-bird has become sufficiently well known in Western Australia to have had streets and sporting teams named after it. More significant, however, is the impact that it has had on conservation in Australia. The rediscovery and conservation of the Noisy Scrub-bird exemplify its most important relationship with humans, as a symbol both of what might have been lost and of what can be done in order to reduce the loss of biodiversity that the world is currently facing. Even before the species' rediscovery it had an influence on human thinking and behaviour: scientists were fascinated by

the intriguing questions that it raised, and ornithologists were compelled to explore infrequently travelled areas of the south coast in search of it. Few birds indeed have had a memorial raised to their "memory". When it was rediscovered, the plight of a small bird on the brink of extinction sparked unexpected interest and determination from conservationists of the time. The success of those conservationists of the early 1960s was unprecedented in Western Australia, and occurred two decades before the better-known "battles" over the Franklin Dam, in Tasmania, or the logging of Terrania Creek, in New South Wales. Furthermore, the Noisy Scrub-bird has been an "icon" threatened species in Australia for nearly 20 years, and it even has an international profile. The success of the conservation programme has encouraged other, similar initiatives for threatened species not only in the state of Western Australia, where recovery programmes for the Western Bristlebird (*Dasyornis longirostris*) and the western population of the Ground Parrot (*Pezoporus wallicus*) are directly based on the procedures developed for the Noisy Scrub-bird, but also throughout the entire country of Australia.

Status and Conservation

The ranges of both members of this family have contracted substantially since the mid-nineteenth century, and both currently exist in very small populations. The Noisy Scrub-bird was at one time thought to have been exterminated, but a very small population was rediscovered in 1961. Under the care of conservationists, it has made a steady return from the very brink of extinction.

In the nineteenth century, soon after its discovery, the Noisy Scrub-bird appeared to be reasonably common within a small region around the King George Sound, in south-west Western Australia. Over three or four decades from the mid 1840s onwards, it remained common enough for museum collectors to gather a few specimens, despite the species' elusive nature. One contemporary writer stated that it was "not, strictly speaking a rare bird, but is rarely seen". Nevertheless, by the turn of the century the scrub-bird had become decidedly rare, and ornithologists failed to find it in any of its known habitats. Through the first half of the twentieth century the species was believed to be extinct, since many dedicated searches in areas thought to be suitable had been unsuccessful.

In 1961, local naturalists found a tiny population of Noisy Scrub-birds on Mount Gardner, at Two Peoples Bay, east of Albany. Fewer than 100 individuals were all that remained of the species, and they were confined to a single location. The bird's limited habitat was under threat from frequent wildfire, unrestricted access, and the imminent development of a town site at the foot of the mountain. The combination of the Noisy Scrub-bird's seriously precarious situation, its elusive nature and mysterious relationships, and a long history of scientific interest in the species inspired concerted action by local and international conservationists to save the bird from extinction.

Within a few years, Two Peoples Bay Nature Reserve was established in an effort to protect the small population. This protected area encompassed all known Noisy Scrub-bird habitat. A number of biological studies were carried out, with the aim of improving knowledge of the species and its ecological relationships. Although the population trend was stable, the vulnerability of the single population in the Mount Gardner area was of major concern. If the species was to thrive, it needed more habitat than was available within the Two Peoples Bay Nature Reserve. In 1976, a small captive-breeding colony was set up in an attempt to breed the birds for a reintroduction programme. Even though the scrub-birds mated, nested and laid eggs, only one captive-bred young was raised to maturity during the five-year project.

Careful management of the reserve, and especially the exclusion of fire, had resulted in some growth in the wild-living population in the late 1970s, and a reintroduction programme, based on individuals captured in the wild at Two Peoples Bay, was begun in 1983. It was hoped that this programme would allow the population to increase in size and, by extending its geographical spread, would reduce the species' vulnerability to wildfire. Although several reintroduction attempts failed to lead to the establishment of viable populations, success was achieved at four sites. In the 1990s, these new populations resulted in

*The **Noisy Scrub-bird** builds a dome-shaped nest out of grasses. It is often placed c.20 cm above the ground, with a loosely woven ramp leading up to a side entrance, and a slight hood protecting the nest from above. An alternative site is in sedge-beds or thick undergrowth, wherein the nest is placed higher above the ground. The clutch consists of a single egg, which is incubated for 5-6 weeks before it hatches, an extraordinarily long period for a small passerine. Males appear to be polygamous, and they play no part in nest construction, incubation or the provisioning of nestlings.*

[*Atrichornis clamosus*, Two Peoples Bay Nature Reserve, Albany, Australia. Photo: Graeme Chapman]

*After its discovery, the **Noisy Scrub-bird** was thought to be common in a small range in Western Australia, but by the 1900s it had declined dramatically. Indeed, it went more than 50 years without being seen, and it was suspected to be extinct before being found again in 1961. The success of this rediscovery was tempered by the grave situation of the species: only an estimated 100 individuals survived. A conservation effort sprang up, leading to the establishment of Two Peoples Bay Nature Reserve. Because of this protection, along with several reintroduction programmes, numbers began to increase, and the population now exceeds 2000 individuals.*

[*Atrichornis clamosus*, Two Peoples Bay Nature Reserve, Albany, Australia. Photo: Jiri Lochman/ Lochman Transparencies]

major growth of the Noisy Scrub-bird population. The birds which were translocated to Mount Manypeaks, to the east of Two Peoples Bay, in 1983 and 1985 have produced a population which, by 2001, was four times the size of the original one at Mount Gardner. Noisy Scrub-birds now exist in several populations, spread over nearly 50 km of near-coastal country, in nature reserves and national parks east of Albany. The easternmost point of the species' current distribution is Bald Island, where small numbers were released in 1992. In 2001, the Noisy Scrub-bird's total population was estimated to be in the region of 2000 individuals.

Although a great deal of effort has been expended on the conservation of the Noisy Scrub-bird since its rediscovery some 40 years ago, the work done in the name of this one species has been of great benefit to many other animal species. Other birds occurring in Two Peoples Bay Nature Reserve include the globally threatened Western Bristlebird, categorized as Vulnerable, and the Near-threatened Western Whipbird (*Psophodes nigrogularis*), of which the two Western Australia subspecies are regarded as vulnerable; management of the reserve has allowed the numbers of both species to increase. The reserve also protected the last population of Gilbert's potoroo (*Potorous gilbertii*), and this mycophagous marsupial was rediscovered at Two Peoples Bay in 1994.

The Noisy Scrub-bird's improved conservation status was recognized in 1997 when the Western Australian government recategorized it from Endangered to Vulnerable, on the basis of the species' positive population growth. In the last few years, some scrub-birds have been reintroduced to remaining habitat in the Darling Range, south of Perth, near the site where Gilbert had first discovered the species in 1842.

The change from the fire regime of the indigenous people to that practised by European settlers had a damaging effect on Australian wildlife. It is thought that the inappropriate fire regime practised by the early settlers resulted in more intense wildfires, which would have devastated Noisy Scrub-bird habitat in the south-west. In addition, logging of the forest, grazing by domestic stock, and the wholesale clearing of native vegetation for agriculture have all been implicated in this species' rapid decline in the late nineteenth century.

The Rufous Scrub-bird fared better during this period. It was discovered in 1865, on the Richmond River in New South Wales, and was the focus of some early studies. Nevertheless, logging of its rainforest habitat and exploitation of lowland areas for farming have reduced its distribution to higher-altitude rainforest. Its population at the time when European settlers arrived is believed to have been about 12,000 pairs, the majority of which, it seems, inhabited lowland areas. Most of the lowland habitat was cleared in the years immediately following colonization by Europeans, and the species soon became confined to higher-lying forest, mostly above 600 m. Surveys carried out over a century later, in the period from 1979 to 1983, produced an estimate of no more than about 2500 pairs, of which only 730 were of the northern, nominate race. More recent field studies, undertaken at the very end of the twentieth century, indicate that the species, especially the nominate race, has probably suffered a further decline.

The Rufous Scrub-bird is currently distributed in several isolated populations. Many of these are in national parks and are reasonably secure. Fortunately, habitat clearance seems not to be a continuing threat. On the other hand, about 65% of all pairs are found in eucalyptus forest, where suitability of the habitat could be compromised by inappropriate burning and logging practices. As a result, the Rufous Scrub-bird has been placed by BirdLife International in the conservation category of Near-threatened.

Genus *ATRICHORNIS* Stejneger, 1885

1. Rufous Scrub-bird

Atrichornis rufescens

French: Atrichorne roux **German**: Rostbauch-Dickichtvogel **Spanish**: Matorralero Rojizo
Other common names: Eastern Scrub-bird

Taxonomy. *Atrichia rufescens* E. P. Ramsay, 1867, Richmond River, New South Wales, Australia.
Birds from S Queensland (Macpherson Range) described as race *jacksoni*, but considered indistinguishable from nominate. Described taxon *tweedi* (from R Tweed, New South Wales) synonymized with nominate. Two subspecies recognized.
Subspecies and Distribution.
A. r. rufescens (E. P. Ramsay, 1867) - E side of Great Divide from extreme SE Queensland (Mistake Range) S to extreme N New South Wales (S to Gibraltar Range).
A. r. ferrieri Schodde & Mason, 1999 - NE New South Wales (from Dorrigo Plateau S to Barrington Tops).

Descriptive notes. 17-18·5 cm. Small and compact, with short wings, long, graduated tail. Male has head and neck dark brown with indistinct fine dark barring; rest of upperparts dark brown, also with fine dark barring, grading to dark rufous-brown on rump; tail and folded wing finely barred; blackish triangle (broadly tipped white in fresh plumage) from centre of chin to throat and breast and to side of upper belly, bordered by white malar stripe that extends as broken, narrower and much less conspicuous pale line to side of belly; sides of neck and breast and flanks buff-brown with fine barring; rest of belly and vent a rich buff, becoming rich rufous-brown with fine barring on undertail-coverts; large eye black or dark brown; short bill wedge-shaped, merging with flat head, upper mandible dusky to blackish with creamy tip, lower mandible cream-coloured; legs light greyish-pink. Female is smaller than male, with dark throat patch smaller and sometimes indistinct. Juvenile is more reddish-brown above with bars fainter, throat dull greyish, mostly uniform reddish-brown below, rear flanks faintly barred. Race *ferrieri* is slightly paler than nominate, dark area at side of lower breast smaller, belly slightly yellower, tarsus shorter.
Habitat. Subtropical and temperate rainforest, including beech (*Nothofagus*) forest, and adjacent eucalypt (*Eucalyptus*) forest with rainforest understorey. Occurs in wet gulleys, along watercourses, on ridges and escarpments of mountain ranges, in treefall areas. Confined to highland forests between 600 m and 1300 m.
Food and Feeding. Poorly known. Beetles, scrub-snails (*Helix*) and snail eggs recorded as taken; probably some plant seeds eaten. Forages on ground for small invertebrates; lifts leaves with the bill and head; scurries beneath leaf litter, using head as a shovel; scratches the ground to reveal prey.
Breeding. Poorly known. Season Sept-Nov. Male possibly polygynous, takes no part in nest-building, incubation or brood-rearing, occupies permanent territory of c. 1 ha or slightly larger. Nest a dome with side entrance, constructed from dead grasses such as *Xerotes*, *Gahnia* and *Carex*, sometimes some pieces of dead tree-fern incorporated, lined with cardboard-like substance made from wood fibre, placed close to ground, usually at c. 15 cm, in clump of sedges or tussock or small tree-fern. Clutch 2 eggs; incubation period uncertain, thought to be 36-38 days; nestling period not known, suggested as 3-4 weeks; young fed by mother for at least 3 weeks after leaving nest.
Movements. Sedentary. Although one immature travelled at least 20 km from nearest suitable breeding habitat, dispersal over such distances likely to be rare.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Eastern Australia EBA. Occurs in scattered populations along the Great Dividing Range. Total of 2400 territories estimated in 1984, only 730 of which were of nominate race; more recent surveys indicate that population has declined. Many of the surviving individuals are in national parks and are reasonably secure. Most of the lowland forest previously occupied by this species was cleared soon after European settlement, and it became confined to higher areas, mostly above 600 m. Remaining habitat not subject to clearance, but inappropriate burning and logging practices could potentially render it unsuitable.

2. Noisy Scrub-bird

Atrichornis clamosus

French: Atrichorne bruyant **Spanish**: Matorralero Bullicioso
German: Braunbauch-Dickichtvogel
Other common names: Western Scrub-bird

Taxonomy. *Atrichia clamosa* Gould, 1844, Darling Range, Western Australia.
Proposed race *campbelli* (from King George Sound) considered indistinguishable. Monotypic.
Distribution. Western Australia, in coastal and near-coastal areas between Albany and Cheyne Beach; reintroduced at several sites, including recently near Waroona (in Darling Range, S of Perth). Introduced on Bald I.

Descriptive notes. Male c. 23 cm, 50-60 g; female c. 19·5 cm, 34 g. Rather small, with short rounded wings, long graduated tail. Male is mid-brown above, with fine, dark vermiculations on head, becoming broader barring on back and extending to tail; wings faintly barred (variable); chin white or off-white; broad dark band (with prominent white feather tips in fresh plumage) extends from centre of throat, sometimes from central chin, to upper breast, bordered by very broad white malar stripe; breast side dark greyish-brown; belly light buffish, flanks cinnamon with

dusky barring, becoming more rufous towards rear, ventral area deep rufous; large eye dark brown; upper mandible dark grey, central ridge extends (sometimes with small hump) into forehead feathers, lower mandible pinkish and curving markedly down at gape; legs light brown or greyish. Female is noticeably smaller than male, lacks dark throatband, chin creamy, generally more buff below, grading to rufous posteriorly. Juvenile is more uniform, dark rufous-brown, greyer posteriorly.

Habitat. Dense scrub and the shrubby understorey of low forest; frequents gulleys, swamps, watercourses, and dense thickets on sides of hills, often around rocky outcrops. Sometimes also found in dense low heath. From near sea-level to 500 m.

Food and Feeding. Eats a wide range of invertebrates, but seems to prefer ants (Formicidae), beetles, spiders, orthopterans and various larvae. Vertebrates sometimes taken; small frogs (e.g. *Crinia georgiana*), skinks (Scincidae) and geckos (e.g. *Phyllodactylus marmoratus*) recorded as fed to nestling. Forages mainly among deep leaf litter on the ground, also in rotting logs and debris and among stems and leaves of understorey plants. Pokes the bill into crevices and beneath leaves; lifts leaves with the head. Relies on flushing prey from litter and debris; does not scratch substrate.

Breeding. Season Apr-Oct, during austral winter, most eggs laid in Jun. Male probably polygynous, plays no role in nest-building, incubation of eggs or brood-rearing, occupies permanent territory of c. 5 ha. Nest dome-shaped, typically c. 18 cm high, 12·5 cm wide and 14 cm deep, with side entrance, constructed from grasses (mostly *Lepidosperma* and *Anarthria*, less commonly *Gahnia*, *Agonis*, *Dryandra*), inner layers quite tightly bound, outer layers looser, walls and floor up to 5 cm thick, bottom half of chamber lined with cardboard-like material made from wood pulp, often a small "hood" above entrance, usually also a loosely woven runway up to 20 cm long sloping up to entrance; typically c. 80 cm above ground, sometimes lower, and well hidden in clump of sedge or debris, occasionally in dense shrub or pile of debris. Clutch 1 egg; incubation period 5-6 weeks; chick brooded after each feed in early stages, daytime brooding ceases after c. 10 days but continues at night until fledging, chick fed with relatively large items (including small vertebrates) as it grows, female removes faecal sacs directly from cloaca of nestling; fledging period 3-4 weeks; after leaving nest, young remains close to its mother for up to 6 months. Success rates up to 90% in some populations; nests possibly preyed on by yellow-footed antechinus (*Antechinus flavipes*), possibly also by southern bush-rat (*Rattus fuscipes*). Female capable of breeding in first year, male at 2-3 years.

Movements. Generally sedentary. Some males disperse up to 10 km from natal area, but many appear to remain in or near natal territory until they establish a new territory or successfully challenge another territorial male.

Status and Conservation. VULNERABLE. CITES I. Restricted-range species: present in Southwest Australia EBA. Was considered extinct, but small population, of fewer than 100 individuals, rediscovered in 1961 at Mt Gardner, at Two Peoples Bay; latter area was soon thereafter designated a nature reserve. Was apparently reasonably common in 19th century, but by beginning of 20th century had become extremely rare; activities associated with European settlers (e.g. logging of forest, grazing by domestic stock, wholesale clearing of native vegetation for agriculture, and large-scale, intense wildfires) almost certainly responsible for the species' rapid decline. Over next 50 years, many comprehensive searches by ornithologists failed to find the scrub-bird, and it was believed to be extinct. Following its unexpected rediscovery in 1961, population at Two Peoples Bay increased steadily as a result of careful management, especially fire control, and from 1983 onwards individuals were captured there for reintroduction attempts elsewhere (after failure of captive-breeding programme in late 1970s); these were successful at four sites, and in 1990s resulted in major growth of the species' population. Total population estimated at 1900-2000 individuals in 2001, by which year birds translocated in 1983 and 1985 to Mt Manypeaks, E of Two Peoples Bay, had produced a subpopulation four times the size of original Mt Gardner one. Currently distributed along almost 50 km of coast, mostly in protected areas, and including introduced population on Bald I; locally common within this tiny range. Reintroduced at three sites near type locality in the Darling Range, S of Perth, at end of 1990s. Population of Albany management area increased from 588 singing males in 1999 to 765 in 2001, in spite of fires during 2000.

Class AVES
Order PASSERIFORMES
Suborder MENURAE
Family MENURIDAE (LYREBIRDS)

- Large, mainly ground-dwelling birds with short, rounded wings, long legs and a long tail.
- 76-103 cm.

- Eastern Australia.
- Mostly moist forest with dense understorey and some bare areas.
- 1 genus, 2 species, 4 taxa.
- 1 species threatened; none extinct since 1600.

Systematics

The scientists who examined the specimens of the Superb Lyrebird (*Menura novaehollandiae*) sent to England soon after the species' discovery by Europeans, in 1798, were puzzled as to the bird's affinities. This is reflected in the variety of common names ascribed to the species during the following fifty years, which included "Native Pheasant", "Peacock-wren" and "New South Wales Bird-of-paradise". One dominant early view was that lyrebirds belonged to the order Galliformes, but this had to be abandoned when the nesting habits and altricial development of the young menurids became better known.

The first evidence that *Menura* is, in fact, a passerine was published in 1840. Since then, two issues have dominated the debate concerning the affinities of the lyrebirds. These relate to the precise nature of their relationships with the other passerines, and to which of them they are most closely related. The suggestion that their closest relatives are the scrub-birds (Atrichornithidae) originated in the 1870s. In 1873, A. H. Garrod, on the basis of anatomical studies, concluded that the lyrebirds and the scrub-birds were closely allied, and he placed them next to the oscines, from which they differed in having fewer syringeal muscles. This treatment was followed by all authors for the ensuing century, with the two groups being placed in various taxonomic categories, but always distinct from all other passerines. From the mid-twentieth century, several authors placed the lyrebirds and scrub-birds between the suboscines and oscines in a separate suborder, Menurae, and this is the treatment followed herein.

In the years since the early 1980s, the conclusion that these two families are each other's closest relatives, but that neither is very closely related to any other passerine family, has been supported by documentation of similarities in body pterylosis and in the musculature of the fore and hind limbs, as well as by genetic analysis using the technique of DNA-DNA hybridization. Indeed, in 1990, the two groups were even united in a single family by C. G. Sibley and J. E. Ahlquist. On the other hand, further similarities that could be construed as indicating a close relationship, such as some features of the skull and skeleton, may be no more than shared passerine resemblances or may be the result of convergence towards a terrestrial lifestyle. The two families differ in traits such as wing and tail pterylosis, natal down and plumage-development patterns, and the DNA-DNA hybridization distances between them are actually quite large. Nevertheless, although there are currently no DNA-sequence data for scrub-birds, there is a general consensus that they are the lyrebirds' closest relatives.

Classification based on DNA-DNA hybridization grouped the lyrebirds, the scrub-birds, the Australasian treecreepers (Climacteridae) and the bowerbirds (Ptilonorynchidae) together in one superfamily. Subsequent analyses using protein electrophoresis and microcomplement fixation have not, however, supported this grouping. They constantly isolated the lyrebirds as a sister-lineage to the other oscine songbirds. This latter pattern of relationships has now been corroborated by recent DNA-sequencing studies examining both mitochondrial and nuclear genes. Although they have fewer intrinsic syringeal muscles than the 5-9 pairs typical of the oscines, it now seems that the lyrebirds may be most appropriately placed in the oscine suborder of the Passeriformes. It is certainly clear that they originated in the Australasian region.

The fossil record of the family is very poor. A single species, *Menura tyawanoides*, was described from the middle Miocene deposits at Riversleigh, situated at 19° S in the northern part of western Queensland.

Morphological Aspects

The two lyrebirds are primarily ground-dwelling birds, their flight being largely restricted to episodes of gliding downhill. They are among the very largest of the passerines, being of the same size as a *Phasianus* pheasant, and they have short, rounded wings. Albert's Lyrebird (*Menura alberti*) has a wingspan of 76-79 cm, that of the Superb Lyrebird being 68-76 cm. Both species have legs, feet and claws that are long, enabling them to run rapidly and to move litter and dig in the soil with considerable power. They move with a fairly upright stance, with the long tail held closed during terrestrial locomotion. In terms of plumage coloration, both are predominantly dark grey-brown or rufous-brown above and dark grey to light grey-brown below. The plumage of the adult Albert's Lyrebird is distinguished from that of the Superb Lyrebird by being generally more red-brown than grey-brown, especially on the throat, flanks and rump. Lyrebirds have a short, black, slender bill, a black iris and dark grey-brown legs and feet.

The most striking aspect of the Superb Lyrebird's plumage is the adult male's tail. When the bird is walking, this is carried in a horizontal train, with the feathers curving gently upwards and then drooping at the tip. In courtship display (see Breeding), by

The first thing one is likely to notice about lyrebirds is their size: they are amongst the largest of all passerines. Indeed, they look more closely related to pheasants than anything else, and thus their first taxonomic placement was in the order Galliformes. The second notable feature is the tail. Most of the time, when foraging, walking or perching, the tail of the male ***Superb Lyrebird*** *is held closed, as shown here. It consists of 16 highly modified feathers: an outer pair of broad lyre-shaped plumes (from which the species derive their English name), separated by twelve filamentaries with long, flexible barbs. These filamentaries mostly lack barbules, and as such they have a delicate lacy appearance. In this photograph, the outer plumes are partially concealed by filamentaries, but it is possible to make out the club-shaped, black tips and the series of chestnut-coloured, semi-transparent segments at intervals along the inner web. The tail of females is much less spectacular, lacking both lyrates and filamentaries, and appearing simply elongated. The wings of both sexes are brown, short and rounded, and are rarely used for flight.*

[*Menura novaehollandiae victoriae*, Healesville Sanctuary, Melbourne, Australia. Photo: D. Parer & E. Parer-Cook/Ardea]

*The male **Superb Lyrebird** is a famously accomplished songster, interspersing his loud vocal signal with a remarkable range of accurate mimicry. Apart from seven species-specific elements, the repertoire of each male contains a large number of sounds copied from a wide range of sources, such as birds, mammals (including humans) and machines. Males sing throughout the year, but in the breeding season their output increases so that half their time is spent singing. Females produce far less complex songs than males, and only sing under duress, such as when their nests are in danger.*

[*Menura novaehollandiae victoriae*, Healesville Sanctuary, Melbourne, Australia. Photo: Jürgen & Christine Sohns/FLPA]

contrast, the tail is fanned in a 180-degree arc, thrust forward over the back and head and vibrated. It consists of 16 highly modified feathers. The outer feather on each side is known as a lyrate; these feathers are curved in an S-shape, and together they resemble the frame of a lyre, from which the species derives its name. The two lyrates have club-shaped, black tips and a series of chestnut-coloured, semi-transparent bands at intervals along their length. Between the lyrates are twelve filamentaries with long, flexible barbs that mostly lack barbules, so that they have a lacy appearance. The two central median feathers are long and almost devoid of barbs and barbules, giving them a quill-like appearance. They curve upwards at the tip and cross over near their origins. The tail feathers are brown on the upper surface, but underneath they are silvery white, which greatly enhances the visual stimulus created when the tail is inverted in display.

Although the male Albert's Lyrebird also has an impressive tail, this is shorter and less spectacular than that of its congener. The lyrates are unornamented, and the filamentaries and medians are grey rather than white on the underside. The tail simply curves upwards when the bird is not displaying.

In both species, the female's tail is far less modified. Although the lyrates of the female Superb Lyrebird do have some chestnut notches, these are less pronounced than the prominent bands shown by the male.

Juvenile lyrebirds have a plumage similar to that of adult females, except that the rectrices are narrower and more tapered and the throat is more rufous. Male Superb Lyrebirds gradually acquire the characteristic adult tail over their first six to eight years, in a widely varying schedule; females acquire full adult plumage in about their fifth year.

Adult Superb Lyrebirds undergo a complete moult annually. After breeding, males moult all of their tail feathers over a period of 1-3 weeks in spring and early summer, and then replace them in about 14 weeks. Females undergo a more gradual annual replacement of the tail feathers. The primaries are replaced from the inner ones outwards, in spring. In both adults and immature birds, moult of the head and neck feathers occurs in summer and autumn and takes about a month; the body plumage is replaced over a more extended period lasting from spring to summer and even into winter.

Habitat

The family Menuridae is restricted to moist forest habitats in eastern Australia, where it ranges from extreme south-east Queensland southwards to the south-eastern half of Victoria. The discovery of the fossil species *Menura tyawanoides* in the Riversleigh deposits in north-west Queensland, near the border with Northern Territory, indicates that the family's range was probably more extensive in former times. The two extant lyrebirds are found from sea-level to about 1500 m, but they occur principally in the Great Dividing Range and associated mountains.

The Superb Lyrebird inhabits mainly rainforest and wet sclerophyll forest. In subtropical rainforest, it is commonly associated with watercourses where there is a dense understorey that includes ferns, shrubs, vines and epiphytes, but farther south it also inhabits cool temperate rainforest with a more open understorey. It is widespread in wet sclerophyll forests dominated by various eucalyptus (*Eucalyptus*) species, including mountain ash (*E. regnans*), alpine ash (*E. delegatensis*) and mountain gum (*E. dalrympleana*) at higher altitudes and narrow-leaved peppermint (*E. robertsonii*), brown barrell (*E. fastigata*) and manna gum (*E. viminalis*) at lower elevations. In north-eastern New South Wales and south-eastern Queensland, the species is also found in a quite different habitat type, that of dry sclerophyll forest with only a sparse understorey of hard-leaved shrubs interrupted by numerous granite boulders. In addition, it occurs in alpine snow gum (*E. pauciflora*) woodland and coastal eucalypt forests in which banksias (*Banksia*) are prominent. Superb Lyrebirds can live in logged forest, although not in the earliest regeneration stages, and they survive at low densities in forest remnants in cleared farmland. Between 1934 and 1949, this species was deliberately introduced to Tasmania, where it became established in temperate rainforest dominated by beech (*Nothofagus*) and in wet sclerophyll forest.

Albert's Lyrebird, which is distributed over a range of 100 km in south-east Queensland and north-east New South Wales, is confined to subtropical rainforest and wet sclerophyll forest with a very moist understorey of shrubs and vines. Like the Superb Lyrebird, it occurs both along watercourses and on the slopes and ridges of steep mountain ranges. Key factors promoting higher densities of this species are the presence of a eucalypt canopy, higher rainfall, lower temperatures, and more forest-floor litter.

Although lyrebird habitats typically have a dense understorey, the birds require areas of bare forest floor for foraging. Their foraging behaviour (see Food and Feeding) promotes the growth of shade-producing plants, and these help to keep such areas clear of ground cover and hence maintain an accessible food source. It is conceivable that lyrebirds prefer younger forests precisely because the higher tree density reduces ground cover. Equally, however, the males' display sites are commonly surrounded by quite dense vegetation, often resulting from a natural break in the canopy and greater light penetration. This may be important in providing displaying males with protection from predators. The nests of lyrebirds are built in steep-sided watercourses, as well as on slopes and ridges away from creeks.

General Habits

Although lyrebirds spend most of the day on the ground, they roost at night in trees, often 20-45 m above the ground. The ascent at dusk involves a series of clumsy leaps accompanied by wing-flapping, and the morning descent is made in a series of glides from branch to branch. Lyrebirds are normally extremely wary and unapproachable, this being especially true of Albert's Lyrebird, the ecology and behaviour of which are consequently poorly documented.

In the case of the Superb Lyrebird, two-thirds to three-quarters of the sightings made in one extensive investigation were of single individuals. Adults, in particular, are solitary throughout the year. Non-territorial, immature birds, however, often associate in small, single-sex and mixed-sex groups, which may be joined transiently by adults whose territories they traverse, especially in the non-breeding season. There is much social interaction, including display and chasing, within these groups, and the members sometimes roost together at night.

The agonistic behaviour of lyrebirds is aural and visual. Male territorial song seems both to attract mates and to repel rivals. Adult male Superb Lyrebirds also react to territorial intrusion by rival males with a "skypointing display", in which the neck is extended and the head is pointed almost vertically upwards and jerked from side to side. This is often followed by prolonged chasing accompanied by calling. "Full Display" (see Breeding) can form part of agonistic interactions among males, too. Such interactions sometimes escalate into fighting, in which the combatants strike each other with the bill and claws. Similarly, adult females sometimes threaten and fight one another quite vigorously.

When alarmed, lyrebirds commonly pause, visually scan their surroundings, listen and vocalize. Intense alarm stimulates piercingly loud whistles, immediately after which the birds either rapidly flee or seek cover and freeze. Various other reactions to potential danger in the vicinity of the nest are mentioned below (see Breeding).

Bathing is probably a daily activity for the Superb Lyrebird. This usually takes place in shallow streams and pools of water, the birds at times travelling long distances to reach them. After wading into the water, the lyrebird immerses its entire body, spreads its wings and ducks its head beneath the surface, while splashing about vigorously. It then leaves the water and jumps up to a perch, where it shakes the water droplets from its plumage and proceeds to preen, a process which includes the drawing of the entire length of each tail feather through the bill. Head-scratching is by the indirect method, with the foot brought over the top of the wing. In addition, the Superb Lyrebird preens at other times of the day, at favoured sites in its territory; indeed, it is claimed that it may indulge in up to eight bouts of preening daily. Members of groups of immatures often bathe together.

Lyrebirds make further use of pools and streams as sources of fresh water for drinking. They also drink from water trapped in hollows in logs, fungi and tree forks.

Voice

One characteristic for which the lyrebirds are renowned is their spectacular vocal behaviour, particularly the male's song with its large component of mimicry. Males sing at all times of the year,

*The bulk of the **Superb Lyrebird**'s diet is made up of adult and larval invertebrates, including earthworms, centipedes, cockroaches, beetles, earwigs and the like. In addition, a few small vertebrates are eaten, such as frogs and lizards. All these items are picked from the ground or from rotting bark and logs. The usual technique is to clear away leaf litter and dig into the soil with the powerful feet, to depths of up to 15 cm. Although individuals generally forage alone, they are often accompanied by smaller passerines, such as Pilotbirds* (Pycnoptilus floccosus)*, which are attracted to the insects disturbed by the lyrebird's diggings.*

[*Menura novaehollandiae*, Barrington Tops National Park, New South Wales, Australia. Photo: Roland Seitre]

but with maximum frequency and intensity during the peak period of the breeding season, in June-August. At this time, the diurnal singing rhythm exhibits early-morning and mid-afternoon peaks, although the midday decrease in vocal activity is less pronounced at the height of the egg-laying period. Each day during the main part of the breeding season, males spend more than four hours, over 50% of the daytime, in song, and they even sing at the roost before dawn and after dusk. Song is loud and complex, and it carries for 1 km or more under ideal conditions. Adult males respond to playback of song by approaching the amplifier and displaying aggressively, even if the recording is of their own song or of song from which all the species-specific elements have been removed.

The song of the male Superb Lyrebird consists of 70-80% mimicry interspersed with seven species-specific vocalizations, which include "Territorial Song", "Twanging", "Galloping" and "Clicking" calls. Bouts of song last from a few minutes to more than 40 minutes. Territorial Songs are evenly dispersed within song, last 6-10 seconds, and may themselves contain fragments of mimicked calls, such as the initial part of the Laughing Kookaburra's (*Dacelo novaeguineae*) laughing call or calls of the Yellow-tailed Black-cockatoo (*Calyptorhynchus funereus*). Males at a particular location often share several versions of Territorial Song, the shared repertoire being stable over at least a few years. There are, however, marked geographical dialects in Territorial Song, and many dialects may exist within a relatively small area if the lyrebird's populations are sufficiently acoustically isolated by habitat discontinuities or topography. The Twanging calls given in song sound like metal wires being struck, Galloping calls resemble the hoof sounds of a galloping horse, and Clicking comprises a series of soft clicks that may last for several minutes.

Most of the mimicry contained in the male Superb Lyrebird's song is of native and introduced birds. The preferred sounds are usually brief songs or call notes, or fragments of more complex songs. An individual's repertoire is extensive and can regularly include calls of twenty or more other bird species; collectively, up to 25% of the local avifauna may be mimicked by the males in a particular location. A few mammals, including the koala (*Phascolarctos cinereus*), the dingo (*Canis dingo*) and the common brush-tailed possum (*Trichosurus vulpecula*), are also mimicked. In addition, male Superb Lyrebirds mimic other natural sounds, such as the wingbeat noise of a flock of parrots (Psittacidae), the ripping of wood by feeding cockatoos or the creaking of a tree limb. The degree of control of timing in mimicry is remarkable. Males can, for example, imitate the antiphonal calling of a group of kookaburras or a pair of Eastern Whipbirds (*Psophodes olivaceus*). They also interrupt their own singing to mimic vocalizations produced concurrently by another species or another lyrebird and then resume where they left off, as though there had been no interruption. Spectrographic analysis shows that mimicked calls are in most cases very accurate representations of the model species' calls.

The degree of mimicry of man-made sounds by Superb Lyrebirds living in the wild has been exaggerated, and the phenomenon is, in fact, quite rare. Nevertheless, there are a few reasonably credible records of imitation of human whistles and speech fragments by wild individuals, as well as some authentic accounts of captive males mimicking sounds produced by vehicles, musical instruments and a camera motor drive.

Vocal mimicry by male Superb Lyrebirds also exhibits geographical dialects, the species mimicked reflecting variations in local avifaunas. Clearly, mimicry is for the most part learnt from other males in the population, rather than being directly copied from the model species. The best evidence for this is provided by the introduced Tasmanian populations of the Superb Lyrebird, which have retained for more than a generation their mimicry of mainland species that are absent from the island. As Tasmanian endemics were also being mimicked within twenty years of the introductions, however, some direct imitation of model species does occur. Young birds typically take a year or more to perfect their mimicked repertoire.

Males give a subdued version of song directly to females throughout the year. In this version, termed "Whisper Song", mimicry is more restricted and may include calls of bird species less commonly mimicked in the full song.

Compared with that of its congener, the song of the male Albert's Lyrebird has fewer species-specific components, the most prominent being Territorial Song and "Gronking Song". Each loud Territorial Song lasts up to ten seconds; as with the Superb Lyrebird, males at a given locality share several slightly different themes, the common repertoire is stable over many years, and there are regional dialects. Gronking Song commonly consists of repeated loud "gronk" notes, which are preceded by crackling and cracking sounds and succeeded by a series of soft, rhythmic notes. The remaining 70% of the song is pure mimicry, but with a smaller number of species mimicked than is the case with the Superb Lyrebird. Typically, three to eight co-existing bird species are mimicked, as also are some other natural sounds, but mimicry of the Satin Bowerbird (*Ptilonorynchus violaceus*) is dominant and even its local dialects are reproduced. In contrast to the Superb Lyrebird, Albert's Lyrebird utters mimicked sounds in a stereotyped order, rather than randomly. As with its southern congener, mimicry of domestic animals, tools and vehicles has been reported, and mimicry is probably culturally transmitted, because some species are mimicked in their complete absence. A degree of mimicry is also incorporated into both Territorial and Gronking Songs.

Females of both lyrebird species occasionally sing, although less "skilfully" than males. Their songs consist mostly of varied mimicry, lacking the species-specific elements of the males' songs, and they are generally given only in situations of danger or threat to the nest or young.

In addition to their famous songs, lyrebirds have several other vocalizations. These include high-pitched alarm whistles and guttural, clucking calls. In situations of intense alarm, as when a predator is close to the nest, the female utters an extremely loud, shrill shriek or scream.

Food and Feeding

Very little is known about the diet and foraging behaviour of Albert's Lyrebird. The following details, therefore, apply almost exclusively to the Superb Lyrebird. The principal food of this species is adult and larval invertebrates, which are obtained from the soil and from beneath bark on rotting vegetation. It occasionally captures invertebrates from litter trapped in epiphytes and tree forks.

Analyses of the stomach contents of adult Superb Lyrebirds have revealed the presence of a number of prominent dietary items. These are earthworms, woodlice (Isopoda), millipedes (Diplopoda), centipedes (Chilopoda), scorpions (Scorpiones), spiders, cockroaches (Blattodea) and their egg cases, both adult and larval beetles (Coleoptera), earwigs (Dermaptera), two-tailed bristletails (Diplura), fly larvae, bees, ants, and adult and larval moths. Prey eaten in smaller numbers include snails, the small terrestrial crustaceans known as amphipods and decapods, bugs (Hemiptera), stick-insects (Phasmatidae), small frogs, lizards of the family Scincidae, and the seeds of several plants. Adult and nestling diets strongly overlap. Additional prey items recorded as being fed to nestlings are the arthropod *Peripatus*, springtails (Collembola), crickets (Gryllidae) and grasshoppers (Acrididae), but more extensive sampling of the adult's diet may identify these items, too. The abundance of the soil invertebrates eaten by Superb Lyrebirds varies spatially and seasonally, being lowest in winter, when the birds start breeding, and higher in spring and, especially, autumn. The Superb Lyrebird has a slow passage rate of food through the gut, but assimilates energy from its diet very efficiently.

Superb Lyrebirds forage mainly on the ground and solitarily. In the summer and early autumn, they seek food more in the moist gulleys than on the drier slopes. They first clear away any litter or large, dead branches and then dig down into the soil, using both of their powerful, clawed feet, to depths of up to 15 cm. During steady, prolonged foraging bouts, their excavation sites are, on average, less than 2 m apart and 0·25-0·5 m^2 in area. Typically, a bird spends about 1·5 minutes at a site and

*The rarer of the two species, **Albert's Lyrebird**, inhabits a small range in the far south of Queensland and the far north of New South Wales. The males of this northern form are slightly smaller than their southern cousins, and the lyrate feathers in their tails are simpler in design. During the breeding season they construct a platform of twigs, raised just above the forest floor, and from this podium they sing and perform displays. In format, the displays of the two species are similar, differing only in the details of their execution. Likewise, Albert's Lyrebird is capable of copious loud singing and mimicry, although its voice is slightly less complex than that of the Superb Lyrebird, and the mimicry tends to be given in a more stereotypic, less random fashion.*

[*Menura alberti*, near Wilsons Peck, Queensland, Australia. Photo: Wayne Lawler/ Auscape]

catches 25-30 prey. About five digging movements are required for the capture of each prey item. Feeding is fairly unselective, the birds taking all suitably sized prey encountered. Foraging routes can be straight or very circuitous, although the bird rarely retraces its steps during any single bout of foraging. By burying leaf litter beneath the soil when foraging, lyrebirds probably hasten its breakdown and speed up nutrient-cycling in the forest. Various other birds, including Pilotbirds (*Pycnoptilus floccosus*), Eastern Yellow Robins (*Eopsaltria australis*) and White-browed Scrubwrens (*Sericornis frontalis*), sometimes accompany foraging Superb Lyrebirds, exploiting flushed prey that the lyrebird misses.

From the few data available, it appears that the feeding behaviour of Albert's Lyrebird is similar to that of its congener. Its diet is very poorly known, but seems to consist mainly of adult and larval insects and other soil-dwelling invertebrates. Despite the paucity of information, it is perhaps rather surprising that earthworms have not been confirmed as being eaten by Albert's Lyrebirds. Although a female was seen to take earthworms that had been placed out for her, she fed these to her nestling, rather than consuming them herself.

Albert's Lyrebird generally forages singly, and in relatively open areas lacking dense shrub cover. It scratches through litter and other ground debris, and has been observed to dig into the soil to a depth of 5 cm with its powerful legs and feet. A most intriguing observation, however, was made in September 2001, on the Lamington Plateau, in Queensland. In the early hours of the morning, R. H. Loyn and J. A. Loyn watched a male Albert's Lyrebird as it sat quietly about 8 m above the ground on the base of an epiphytic bird's-nest fern (*Asplenium australasicum*). The bird began to scratch vigorously and to peck at what was presumed to be invertebrate prey; after a few minutes, it flew to the base of another epiphytic fern some 10 m up in a nearby tree, where it repeated the behaviour. A pair of Eastern Yellow Robins quickly took its place on the first fern. From subsequent enquiries made by the observers, it appears that Albert's Lyrebirds have been seen to forage in the same way by other reliable ornithologists. Epiphytic ferns, which are abundant in the rainforest of the region, trap substantial quantities of dead leaf litter and other debris before it reaches the ground. Loyn and Loyn speculated that, as many birds compete for food on the forest floor, a species could gain an advantage by exploiting a different substrate in the subcanopy. A good deal of additional field study is required, however, before one could determine to what extent, if any, this may apply to Albert's Lyrebird.

Interestingly, there is a similar record for the Superb Lyrebird, a species which is far less restricted to rainforest. An individual was seen to forage almost 5 m above the ground in a messmate (*Eucalyptus obliqua*), where it scratched in debris which had collected where two large branches joined the trunk.

*This male **Superb Lyrebird** is busy on one of its dancing grounds, vocalizing with gusto and performing its spectacular courtship display. During the full version of this display the tail is fanned out into a 180° arc, and spread over the head like an umbrella. The filamentous plumes are vibrated rapidly to accentuate the visual effect, and, as if this shimmering veil were not quite impressive enough, he hops from side to side, and leaps several times into the air. This expert choreography is set against a vocal accompaniment impressive in its power and variety. Taken as a whole, the performance is one of the most extraordinary examples of sexual selection and exaggerated courtship ritual in birds.*

Breeding

Breeding begins in the austral winter, generally in June, and ends in early November, but nest-building can commence in the autumn, sometimes as early as March.

Female Superb Lyrebirds first breed when they are 5-6 years old, with males starting at 6-8 years of age. As adults can live for 20-30 years, and as females nest once every year, they potentially have the opportunity to make up to about 25 breeding attempts in their lifetime.

During the breeding season, adult Superb Lyrebirds are solitary and the two sexes defend separate all-purpose territories. A male's territory can encompass, either wholly or partly, those of up to six females, and the boundaries with neighbouring males' territories are narrow zones, rather than abrupt lines. The typical size of a male territory varies among areas, but 2·5-5 ha is the common size range. Each adult male constructs within his territory 20-83 display sites. These are bare, slightly domed, earth mounds measuring 1-2 m in diameter and on which males perform courtship display, especially from June to September. Females visit these mounds for the purpose of copulation.

The male Superb Lyrebird's spectacular courtship display centres on his modified tail (see Morphological Aspects) and his remarkable vocal ability (see Voice). The tail is an extravagant trait that is thought to have evolved through intersexual selection. When a female approaches the mound, the male first gives clicking calls and then performs an "Invitation Display", in which the tail, which is kept folded, is thrust forward, held horizontally

While Albert's Lyrebird (Menura alberti) *builds a stage of sticks on which to dance, the* ***Superb Lyrebird*** *scrapes away leaf litter and digs earth to form a bare, raised mound. Each male constructs large numbers (20-83) of display mounds on his territory, and circulates around these, trying to attract females. When females visit, males display in frenzied fashion until the female consents to copulate, or moves off to assess another male. Males can copulate with several females in a breeding season, but in each case they play no further role in raising the offspring. The female builds the nest, incubates the egg, and raises the fledgling alone.*

[*Menura novaehollandiae victoriae*, Sherbrooke Forest, Victoria, Australia. Photo: Hans & Judy Beste/Ardea]

over the head and back and vibrated rapidly. This is followed by Full Display, in which the tail is fully fanned so that it forms a lacy curtain of about 1·5 m^2 around the male's head and the front of his body. The tail is vibrated as the male first moves from side to side with short, rapid steps and then, with his wings held loosely at the sides, jumps in the air several times. The performance is accompanied by some striking calls and song containing much mimicry (see Voice).

Copulation takes place on a mound after lengthy bouts of male display. Male Superb Lyrebirds appear to be promiscuous, and in the course of a single breeding season they will copulate with several females without forming durable bonds with any of them. Females, when choosing a mate, sometimes visit more than one male and may temporarily leave their territory in doing so. The mating system of the species can be characterized as dispersed male-dominance polygyny, and the males take no part in the building of the nest, the incubating of the eggs and the rearing of the young.

Male Albert's Lyrebirds are also territorial. They, too, perform courtship displays, but on platforms of vines and twigs lying on or just above the forest floor. They scratch the soil beneath the platform a little, but do not build mounds. In the initial phase of courtship, the male holds his tail more open than does the Superb Lyrebird, and he sways from side to side. Full Display closely resembles that of the Superb Lyrebird, the fully open, fanned tail forming a shimmering curtain over the bird's head and body as he executes a high-stepping dance. Courtship display is accompanied by loud singing, which includes interspecific mimicry (see Voice), and the vegetation surrounding the platform often vibrates, possibly as a result of direct manipulation by the male. Copulation probably takes place on the platform. The mating system of Albert's Lyrebird is unknown, but probably resembles that of the species' southern relative.

Lyrebirds' nests, sited in steep-sided watercourses or on slopes and ridges, are bulky and enclosed, with a side entrance that sometimes has an access ramp. The base of the nest comprises a platform or cradle of sticks, and the walls and roof are made from rootlets, small twigs, bark, fern fronds, plant fibre, leaves and moss. The lining consists of fine plant materials and body feathers, which the female is thought to pluck from her own plumage. Sometimes, a sprig of green vegetation is placed on the roof. The completed nest of the Superb Lyrebird weighs 14 kg and takes up to 160 hours to build, the construction work being spread over a period ranging from less than one month to several months. Most lyrebird nests are on the ground or within 2 m of it, but some are situated at heights of up to 20 m or more in trees. Nest-sites include the base of trees, earth banks, boulders, rock faces, fissures and crotches of living and dead trees, clumps of wiregrass (*Tetrarrhena*) or sword-sedge (*Lepidosperma*), exposed tree roots and fallen trunks. For the Superb Lyrebird, the site and the height of the nest do not seem to influence nesting success.

Most female lyrebirds lay between June and August, the clutch consisting of a single egg. Occasional records of two-egg clutches are probably the result of replacement laying, rather than constituting a genuinely larger clutch size. The majority of females, however, make only one breeding attempt annually, even if this fails quite early on. The oval egg has a grey or brown background colour, and irregular dark grey or brown markings over much of the shell. It is approximately the size of a chicken's egg, and that of the Superb Lyrebird weighs about 62 g, on average.

The reproductive cycle of lyrebirds, from egg-laying to the time when the young leave the nest, is unusually protracted. Although many of the relevant details for Albert's Lyrebird are poorly known, they are probably very like those of its relative. The incubation period of the Superb Lyrebird is about 50 days, which is 70-80% longer than would be predicted on the basis of the size of the bird and that of its egg. This surprisingly long period may be partly due to the fact that the female spends less than 50% of the daytime in incubating; in particular, she usually takes two recesses daily, the first of which generally lasts for 3-6 hours. The maximum daily ambient temperature at this time is usually below 10°C, and so, during the long recess, the embryo cools down over about three hours to a level close to ambient temperature, and remains at this level until the female returns.

Because these temperatures are below physiological zero temperature, embryonic growth is effectively suspended for several hours every day and development is consequently protracted. The extended incubation period does not, however, result in the egg losing more water than would be needed to facilitate effective hatching. This is because the porosity of the shell is comparatively low.

Once it has hatched, the Superb Lyrebird nestling also grows at an unusually slow rate. The nestling period lasts for about 47 days, rather than the 29 days predicted allometrically from adult body mass. Again, exposure to low temperatures when the female is not brooding the chick in the early stage of development, before it is endothermic, could be a contributing factor. The low feeding frequency, with respective averages of 16 and 32 feeds daily in the early and late stages in the chick's development, may also be involved. It is not known, however, whether the evolution of the female's brooding and provisioning regimes was shaped by the slow growth of the chick or whether the reverse is the case. The mother carries food to the nestling in her cheek pouches, and each meal comprises, on average, 44 prey items, with a total energy content of about 9 kJ. With this feeding regime, the nestling typically increases from 5% of the adult female's weight to 63% during its development. The female deposits most of her nestling's faecal sacs in a nearby stream or buries them in the soil.

Fledgling care is similarly very protracted, and may commonly last for 8-9 months. The fledgling is fed by its mother about 3·5 times as often as it was in the late stage of the nestling period, but the meals are now much smaller. When the adult females commence nest-building, they are sometimes still accompanied by their offspring from the previous year; successful breeding can, therefore, involve more than one year's commitment.

Incubating females usually flee silently when a human approaches the nest, but during the nestling stage the females show a variety of responses to the presence of a predator or a human in the vicinity of the nest. These include tail display, quiet song incorporating interspecific mimicry, running around while giving alarm calls, and physical attacks on the intruder. Older nestlings often respond to humans by standing, bracing themselves against the back or roof of the nest, and emitting ear-shattering screams that usually attract the mother if she is absent from the nest. Animals that evoke anti-predator behaviour, especially if they are near the nest, include foxes, snakes, kookaburras, ravens (*Corvus*) and various raptors.

The few published estimates of nesting success for the Superb Lyrebird vary from 11-20% to 64%. Some of this variation stems from differences in methods of estimating success. Predation is the main cause of nestling mortality; exotic mammals are strongly implicated in this, but native birds, such as ravens and currawongs (*Strepera*), are probably also involved.

It is likely that the single offspring's slow development is crucial in permitting effective single parenting by the mother and facilitating male parental emancipation and polygyny. Breeding during the winter months is an uncommon phenomenon among Australian birds. In the lyrebirds, it has probably evolved as a consequence of male parental emancipation and single-parent brood care by females, rather than being a selection pressure favouring those behavioural traits.

Movements

Studies of individually recognizable birds, combined with the temporal stability of song types (see Voice), indicate that Superb Lyrebirds are sedentary in all parts of their range. Adults are territorial throughout the year, although territory boundaries are relaxed a little in the non-breeding season, during which some short local movements may be undertaken. Young immature birds are not territorial and move over a much larger area. Natural dispersal is usually over distances of less than 10 km. Superb Lyrebirds will, however, flee considerable distances from bush fires, often unsuccessfully (see also Status and Conservation).

The Superb Lyrebird's weak powers of flight and its sedentary nature may partially account for its slow rate of range expansion in Tasmania. Since its introduction there in the 1930s and 1940s (see Habitat), its spread has averaged only about 1 km annually and may have been particularly slow until the late 1980s.

Knowledge of the movements of Albert's Lyrebird is negligible, but the species is thought to be sedentary. Nevertheless, some post-breeding dispersal over short distances seems possible.

Relationship with Man

Aboriginal people appear not to have hunted lyrebirds to any significant extent, and these birds, unlike many other native animals, do not feature greatly in their rock paintings. Even so, indigenous Australians were obviously familiar with the Superb Lyrebird's vocal ability. Of the many names given to the species by aboriginal tribes, "Beleck-Beleck", "Buln-Buln" and "Bullan-Bullan" are clearly phonetic renditions of its calls.

The Superb Lyrebird first became known to Europeans in 1797. A former convict, John Wilson, who had been living with aboriginal people for some years, surrendered to the colonial authorities of New South Wales clad only in a kangaroo-skin apron, and he reported the existence in "the bush" of a strange, pheasant-like bird. In the following year, John Price, a young servant of the colony's governor, collected the first specimen of this bird, in the Blue Mountains. The species was initially referred to as *Menura superba*, which probably meant "the superb bird with the crescent-moon tail" and alluded to the transparent notches in the adult male's tail. Early confusion with regard to the bird's systematic affinities (see Systematics) resulted in its being given many different vernacular names. Ironically, the one that persisted, lyrebird, was given to it by some of the English scientists who examined the early specimens, and who believed that the male's remarkable tail was held in the shape of a lyre throughout display, rather than, as is in fact the case, momentarily.

In the late 1800s and early 1900s, the tail feathers of Superb Lyrebirds became fashionable as household ornaments in the cities of eastern Australia and overseas. As a result, the birds were killed in great numbers (see Status and Conservation).

Albert's Lyrebird was "discovered" by Europeans in the mid-1800s and named after the reigning monarch's consort, Prince Albert. It, too, was hunted for trophies and meat in the early years after its discovery, but to a lesser extent than was its southern congener.

Fortunately, attitudes towards lyrebirds are now dramatically different, and the Superb Lyrebird, in particular, has achieved an almost iconic status in Australia. Most of the pioneering research on this species was conducted in Sherbrooke Forest, in outer Melbourne, where some of these long-lived, normally shy birds have become so accustomed to people that they can be approached and followed at close quarters for long periods of time. The Superb Lyrebird's song was first broadcast from this location to a national audience in 1931, and subsequent gramophone, video and television material has emanated mainly from this site, too. The bird has appeared on postage stamps and is featured on the current Australian ten-cent coin. Its courtship display and song have inspired a ballet, Sir Robert Helpman's "The Lyrebird", as well as passages in the music of the French composer Olivier Messiaen, whose "Saint François d'Assise" and "Eclairs sur L'Au-Delà" incorporate some of the Superb Lyrebird's remarkable vocalizations.

Status and Conservation

Albert's Lyrebird was considered by BirdLife International to be Near-threatened in the early 1990s. Just a few years later, however, in an important publication in 2000, S. T. Garnett and G. M. Crowley estimated that only 3500 breeding adults of this species remained. With a total population consisting of fewer than 10,000 individuals, and the possibility that its numbers might decrease by 10% over the following three decades, Albert's Lyrebird was officially listed as Vulnerable. The Superb Lyrebird, on the other

*The female **Albert's Lyrebird** builds a bulky, domed nest, and into it she deposits a single egg. This egg probably takes well over a month to hatch, after which the nestling grows very slowly: it takes at least 39 days to fledge, and it stays with the female until it is several months old. The population of breeding adults in this species has been reduced to 3500 individuals. As a result of intensive forestry practices, and the replacement of diverse natural forests with eucalyptus or pine monocultures, the population is still declining. However, despite being considered Vulnerable to extinction, many remnant populations of Albert's Lyrebird survive in reserves, and thus their future is relatively secure.*

[*Menura alberti*, Tamborine Mountain, Queensland, Australia. Photo: Lloyd Nielsen/ Oxford Scientific Films]

hand, is currently believed not to be at any risk, and it is still quite common in suitable habitat throughout much of its range.

Historically, both species have been adversely affected by the clearance of habitat for agriculture, forestry and settlement. They do, however, have some ability to survive in harvested forest in which logging events are sufficiently well spaced temporally, and where clearance does not lead to intense invasion by exotic and native ground-cover plants that inhibit feeding. Much of the habitat occupied by Albert's Lyrebird was cleared in the nineteenth century, and suitable habitat for the Superb Lyrebird, too, has been greatly reduced in the last 150 years.

During the nineteenth century and the early decades of the twentieth century, lyrebirds were killed in large numbers by colonists from Europe. Some were hunted for the purpose of providing food, but the great majority were shot for their magnificent tail feathers, which became prized ornaments. The Superb Lyrebird was the main target of the trophy-hunters. In the early 1900s, in one district alone, over 400 were killed in one season, and in Sydney, over a three-year period, two dealers are known to have exported at least 3000 tails of the species. In England, tail plumes were openly sold in London during this period. Adding to these pressures, this lyrebird's eggs were also collected by oologists in considerable numbers in the late nineteenth century. The Superb Lyrebird was accorded full legislative protection in Victoria in 1887, in New South Wales in the early 1900s and in Queensland in 1922, although the fines imposed for breaking the Queensland Act were insignificant. Albert's Lyrebird was also hunted, but on a smaller scale.

At present, the main potential threat to Albert's Lyrebird is intensive forestry practices. Regrowth after logging in wet sclerophyll forest results in increased transpiration, reduced soil moisture and a reduced rainforest subcanopy, as well as an increase in ground cover, often through invasion by lantana (*Lantana camara*). These conditions diminish food availability and accessibility for the birds. Complete replacement of optimal forest habitat by eucalyptus and pine plantations, which are capable of supporting only low densities of lyrebirds, is even more detrimental. Many of the remaining subpopulations of Albert's Lyrebird are fairly secure in reserves, although some may be susceptible to the stochastic and genetic effects to which small populations of animal species are prone.

Habitat loss and alteration are probably the main threats to the Superb Lyrebird, too. Quite a few populations of this species are not presently protected in reserves, and the risk of further deterioration or destruction of native forest is ever present.

In very dry years, bush fires can also represent a threat to lyrebirds. There are several recorded observations of individuals seeking shelter in sites where humans had also sought refuge from the flames and smoke. In addition, both adults and nestlings not infrequently fall victim to predation by mammals, although the extent to which Albert's Lyrebird is preyed upon has been questioned. Predation can, however, have a significant impact on the Superb Lyrebird. Several authors have attributed the decline of this species recorded in Sherbrooke Forest largely to mammalian predation and to increasing urbanization of nearby areas. The mammal species involved are cats and dogs, including dingos, and foxes, but it is unclear whether the impact of these predators exceeds that originally exerted by the native carnivores, such as quolls (*Dasyurus*), which they have displaced.

Lyrebirds fit one classic profile of vulnerable species. They have low reproductive and recruitment rates and they need a lot of habitat in order to satisfy their resource requirements.

Genus *MENURA* Latham, 1802

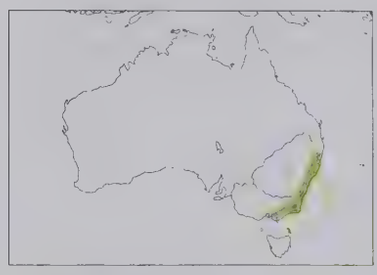
1. Albert's Lyrebird

Menura alberti

French: Ménure d'Albert **German**: Braunrücken-Leierschwanz **Spanish**: Ave-lira de Alberto
Other common names: Prince Albert('s) Lyrebird, Northern Lyrebird

Taxonomy. *Menura alberti* Bonaparte, 1850, Turanga Creek, Richmond River, New South Wales, Australia. Described race *rufa*, from S Queensland, considered undiagnosable. Monotypic.
Distribution. Extreme SE Queensland and extreme NE New South Wales, Australia.
Descriptive notes. 86-93 cm; c. 930 g. Large, with long legs, big strongly clawed feet, and train-like tail. Male has dark grey head and neck, mainly dark red-brown to rufous-brown upperbody and wings; tail 47-57 cm long, comprises ribbon-like central pair of feathers, 12 lacy filamentaries, and a broad outermost pair (lyrates), dark brown above and dark grey below; rufous-brown chin, throat and foreneck, dark grey breast, paler grey abdomen; rear flanks and undertail-coverts bright rufous-brown; bill black; iris dark brown to black, grey orbital ring; legs and feet brownish-grey. Differs from *M. novaehollandiae* in smaller size, more rufous plumage, simpler lyrates. Female is like male, but tail shorter (36-42 cm) and simpler. Juvenile resembles adult female, but rufous coloration brighter, upperparts paler, and rectrices mostly narrower, tapered and pointed; immature as adult female, probably acquires adult tail gradually over several years.

Habitat. Mainly subtropical montane rainforest and wet sclerophyll forest with dense, mesic understorey of shrubs and vines; also inhabits some moderately mature regrowth forest with limited ground cover.



Occurs in gulleys, along watercourses, and on slopes and ridges of steep mountain ranges, mainly above 300 m. Density highest where there is a eucalyptus (*Eucalyptus*) canopy, and increases with increasing rainfall and amount of forest-floor litter and decreasing mean annual temperatures. Absent or at low densities in eucalyptus or pine (*Pinus*) plantations, and absent from dry sclerophyll forest.
Food and Feeding. Very little known. Thought to consume mainly adult and larval insects and other soil invertebrates; diet probably similar to that of *M. novaehollandiae*. Female once seen to feed earthworms to nestling, rather than eating them herself. Forages mostly solitarily, on ground in rather open areas lacking dense shrub cover; scratches through litter, and digs into soil to depths of 5 cm, using powerful legs and feet. Has occasionally been observed to forage above ground, at up to 10 m, in debris trapped in subcanopy epiphytes, e.g. bird's-nest fern (*Asplenium australasicum*).
Breeding. Poorly known. Laying in May-Aug. Mating system unknown; arena behaviour, male sings and displays, raising fanned tail over body and head and dancing, solitarily on terrestrial platform of sticks and vines, copulation probably mainly on platform; nest-building and all subsequent duties by female alone. Bulky nest domed, with side entrance, made from sticks, fronds, leaves and rootlets, lined with moss, fine plant material and feathers; placed mainly on rock face or on the ground, often at tree base, sometimes in tree fork; male territory 5-15 ha, female probably also territorial. Clutch 1 egg; incubation period unknown; nestling period c. 39 days. Longest-lived individual more than 20 years old.
Movements. Poorly documented. Sedentary, both sexes resident in same general area throughout year; possibly move short distances outside territories in non-breeding season. Known to cross small gaps to reach isolated rainforest patches.
Status and Conservation. VULNERABLE. Restricted-range species: present in Eastern Australia EBA. Global population estimated at no more than 3500 mature adults, and thought to be declining. Density in optimal habitat c. 5 "pairs"/km². In 19th century much habitat cleared for agriculture, forestry and settlement, resulting in contraction of range and decrease in numbers. Many subpopulations now found in national parks and other reserves, where fairly secure, but some possibly susceptible to adverse effects that afflict small populations (e.g. genetic inbreeding). Main current potential threat is intense forestry management, especially replacement of optimal habitat by eucalyptus and pine plantations, which support only low densities of lyrebirds.

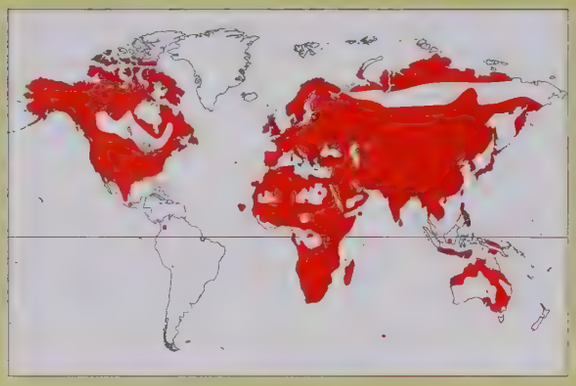
2. Superb Lyrebird

Menura novaehollandiae

French: Ménure superbe **German**: Graurücken-Leierschwanz **Spanish**: Ave-lira Soberbia
Other common names: (Prince) Edward Lyrebird, (Queen) Victoria Lyrebird, New South Wales Bird-of-paradise

Taxonomy. *Menura novaehollandiae* Latham, 1802, upper Nepean River, New South Wales, Australia. Was in the past sometimes referred to as *M. superba*, but that name invalid. Race *victoriae* formerly synonymized with nominate. Three subspecies recognized.
Subspecies and Distribution.
M. n. edwardi Chisholm, 1921 - extreme SE Queensland (Stanthorpe-Killarney region) and NE New South Wales (S, on and E of Great Dividing Range, to R Hunter).
M. n. novaehollandiae Latham, 1802 - SE New South Wales from R Hunter S (on and E of Great Dividing Range) to Victoria border (E of Monaro Tablelands).
M. n. victoriae Gould, 1865 - Australian Capital Territory (Brindabella Range) and extreme SE New South Wales W of Monaro Tablelands, S to E Victoria (S to Dandenong-Strathbogie Ranges and to NE coast).
Introduced (*victoriae*) to Tasmania.
Descriptive notes. Male c. 103 cm, 1100 g; female 76-80 cm, 890 g. Large, with long legs, big strongly clawed feet, and long, train-like tail. Male nominate race has dark grey to brownish-grey upperparts, dull red-brown wash on greater coverts and wings; tail 54-71 cm long, comprises wire-like central pair of feathers, 12 lacy filamentaries, and broad outermost pair (lyrates) with tooth-comb pattern and black club-shaped tip, dark brown above and mostly silvery white below; underparts dark to light brownish-grey, undertail-coverts browner; bill black; iris black, grey orbital ring; legs and feet dark grey. Differs from *M. alberti* in larger size, less rufous plumage, longer tail with more elaborate lyrates. Female is like male, but tail shorter (25-41 cm) and simpler. Juvenile is like adult female, but forehead, chin and foreneck rufous to red-brown, lyrates shorter, narrower and pointed at tip; gradually loses rufous coloration and develops adult tail over several years. Race *edwardi* is generally lighter and greyer than nominate, lyrates slightly less curved; *victoriae* has head, neck and mantle darker, wings slightly darker.



Habitat. Mainly moist forest, particularly cool temperate and subtropical rainforest and wet sclerophyll forest, from sea-level to subalpine zone. Inhabits gulleys, valleys, mid-slopes and ridges; needs bare ground for feeding. In subtropical rainforest, usually associated with dense understorey of ferns, shrubs, vines and epiphytes; in cool temperate rainforest, in areas with more open understorey. Widespread in wet sclerophyll forest with various eucalyptus (*Eucalyptus*) species forming canopy, also in alpine snow gum woodland and coastal eucalypt forest where banksias (*Banksia*) prominent. In Tasmania, introduced population (*victoriae*) now established in temperate beech (*Nothofagus*) forest and wet sclerophyll forest. N populations (*edwardi*) confined to dry sclerophyll forest with sparse understorey of hard-leaved shrubs interrupted by numerous granite boulders.
Food and Feeding. Eats mainly adult and immature invertebrates obtained from soil and under bark; occasionally takes small vertebrates and seeds. Common prey include earthworms, woodlice (Isopoda), millipedes (Diplopoda), centipedes (Chilopoda), scorpions (Scorpiones), spiders, cockroaches (Blattodea), beetles, earwigs (Dermaptera), diplurans, fly larvae, bees, ants and moths; less frequent items include amphipods and decapods, bugs (Hemiptera), stick-insects (Phasmatidae), snails, small frogs, skinks (Scincidae). Additional prey items recorded in nestling diet are the arthropod *Peripatus*, springtails (Collembola), crickets (Gryllidae), grasshoppers (Acrididae). Forages mostly solitarily, on ground; foraging routes straight or winding. Digs in soil to depths of 15 cm, uses powerful feet to rip bark from rotting logs, taking any suitably sized prey encountered. On average, excavation sites used during steady foraging up to 2 m apart, each yielding 25-30 prey items. Prey disturbed by its activity are exploited by other passerines. Foraging thought to play key role in nutrient-cycling and vegetation regeneration. An individual once seen to forage almost 5 m up in a messmate (*Eucalyptus obliqua*), where it scratched in debris trapped where two large branches joined trunk.
Breeding. Laying in Jun-Aug. Male solitary, promiscuous, exhibits arena behaviour, performs courtship with much vocal mimicry on earth mound, tail thrust forward horizontally over head and back and vibrated rapidly, with side-to-side stepping and vertical jumps; copulation on mound, female may visit several males pre-mating; nest-building and all parental care solely by female. Nest bulky, domed, with side entrance, made from sticks, rootlets, twigs, bark, fern fronds, plant fibre, leaves and moss, lined with fine plant materials and body feathers; placed mostly on or within 2 m of ground, sometimes at up to 20 m in tree, main sites include base of tree, earth bank, boulders, rock face, and fissure or crotch of living or dead tree; male territory typically 2·5-5 ha, female territory smaller. Clutch 1 egg; incubation 50 days; nestling period 47 days; independence at 8-9 months after fledging. Success variable, c. 11% to 64%; predation main cause of breeding failure. Female first breeding at 5-6 years, male at 6-8 years. Oldest identifiable individual 25-26 years.
Movements. Sedentary; adults relax territorial boundaries a little in non-breeding season. Young immatures not territorial, move over larger area, often gregariously. Natural dispersal usually less than 10 km. Flees considerable distances from bush fires.
Status and Conservation. Not globally threatened. Formerly hunted, now fully protected. Many mainland populations probably declined in 20th century. Still common in suitable habitat; densities 0·1-0·5 birds/ha. Habitat reduced and degraded by forestry, agriculture and settlement; able to live in forest remnants in farmland, also in logged forest if regrowth more than 5 years old and ground cover limited. Introduced in 1930s and 1940s in Tasmania, where expanded range by c. 1 km annually and expansion continuing. Has low recruitment rate but high longevity. Main threat probably further habitat loss, as some populations not in protected reserves; in addition, predation on adults and nestlings by introduced mammals can have significant adverse impact on numbers.
Bibliography. Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family ALAUDIDAE (LARKS)

- Small to medium-sized terrestrial passerines with drab, mostly brownish or buffish plumage, 10 primaries, outer one often much reduced, long tertials; scutes on posterior surface of tarsus, nail of rear toe usually long and straight, and bill exceedingly variable in size and shape.
- 10-23 cm.

- Africa and Eurasia, with single species in each of Australasia, Madagascar and America.
- Open country, often in arid or semi-arid environments.
- 21 genera, 96 species, 407 taxa.
- 8 species threatened; none extinct since 1600.

Systematics

The honour of heading the sequence of oscine families falls upon the apparently humdrum larks, the Alaudidae, a relatively limited group of small, dun-coloured birds typical of the treeless regions of Africa and Eurasia. This has been the case since the 1930s, when two influential ornithologists, the American A. Wetmore and the German E. Stresemann, independently came to the same taxonomic conclusion. They were united in the conviction that the larks are distinguished by two unique and primitive features which give them a separate identity and point to an evolutionary origin distinct from that of other living oscines.

On the one hand, there is the peculiar morphology of the tarsus, which is latiplantar, having the posterior surface flat and scutellate, covered with prominent scales, instead of being narrow and smooth as in the other families. On the other hand, the syrinx, the organ of voice, is relatively simple in structure, having just five pairs of muscles and with a pessulus, the bony nodule located at the bronchial junction, which is rudimentary. In general, the oscines, or songbirds, have between six and eight pairs of syringeal muscles, as well as a well-developed, ossified pessulus, features which relate to the capacity of such birds to produce complex songs. Nevertheless, the larks, too, are distinguished in the quality of their voices and in their capability as skilled mimics of other birds.

In contrast to these two anatomical peculiarities, which are supposedly primitive and, hence, of particular taxonomic value, other alaudid characters either are too variable within the family as a whole to be diagnostic or are of a comparatively plastic nature, involving, as they do, such features as gait or diet which are all too likely to have produced superficial similarities with other groups as a result of adaptive convergence. For example, the outermost primary, although typically reduced, is very variable in size, perhaps in connection with different migratory habits, and equally variable is the length of the hind claw, which in general is long and straight. The bill is especially variable in shape and thickness, being short and stout in the more granivorous species and long and slender in the more insectivorous ones. Notwithstanding these considerations, earlier taxonomists, such as J. Berlioz, have given weight to the above features and have suggested a placing of the Alaudidae alongside the families of granivorous birds of the nine-primaried group, notably the buntings (Emberizidae), the weavers (Ploceidae) and the finches (Fringillidae), towards the end of the list of oscine families. The contrary ranking, with the Alaudidae at the head of the list, nevertheless prevailed and was adopted in the sequence proposed by E. Mayr and D. Amadon in 1951, and in the "consensus list" which emerged from the XI International Ornithological Congress, which took place in Basel, Switzerland, in 1956.

The "larks-first" tradition has endured to the present day, but there is a growing body of genetic evidence suggesting that the honour belongs instead to several ancient Australasian families. The latiplantar tarsus and the lack of a defined pessulus are probably derived, and not primitive, features. DNA-DNA hybridization studies carried out by C. G. Sibley and J. E. Ahlquist suggest

In larks, as with many passerine families, taxonomic review tends to suggest that the group has been overlumped. One of the most extreme cases involves the Long-billed Lark complex, which has recently been split into five separate species. All these forms, including the ***Benguela Long-billed Lark****, live in southern Africa. The dividing lines between some of these recently split species are still none too clear, notably in the region of Brandberg, where the Benguela meets the Karoo Long-billed Lark* (Certhilauda subcoronata). *Indeed, the latter's local race,* damarensis, *may really belong in the Benguela.*

[*Certhilauda benguelensis kaokoensis*, Brandberg, Namibia. Photo: Andy & Gill Swash]

Described as a species in 1937, ***Barlow's Lark*** *was relegated shortly afterwards to subspecific rank within the* C. albescens-erythrochlamys *complex until analysis of vocal, morphological and genetic differences across the range of this complex led to three species being identified in 1998. The southern coastal race of Barlow's Lark is pale and the southern interior race reddish, corresponding to variations in geology. These plumages look very different, but the populations are identical genetically and vocally.*

[*Calendulauda barlowi patae*, Porth Nolloth, Western Cape, South Africa. Photo: Andy & Gill Swash]

that the closest groups to the larks are, as Berlioz suggested, the Old World sparrows (Passeridae), finches and buntings, and that these form a natural grouping, the superfamily Passeroidea, together with the weavers, the waxbills (Estrildidae), the pipits and wagtails (Motacillidae), the accentors (Prunellidae), the sunbirds (Nectariniidae), the tanagers (Thraupidae) and the New World blackbirds (Icteridae), among others. DNA-DNA hybridization, however, has limited discriminatory capabilities. Other and newer techniques of genetic investigation, such as the sequencing and analysis of conserved genes within nuclear DNA, have now suggested that the affinities of the larks are not with the Passeroidea but rather with another superfamily, the Sylvioidea, a diverse assemblage of passerine families including the long-tailed tits (Aegithalidae), the Old World warblers (Sylviidae), the babblers (Timaliidae), the bulbuls (Pycnonotidae), the white-eyes (Zosteropidae) and the swallows (Hirundinidae). Other families formerly placed in the Sylvioidea by Sibley and Ahlquist now appear rather more distantly related, including the nuthatches (Sittidae), the treecreepers (Certhiidae), the waxwings (Bombycillidae) and the tits (Paridae). Additional support for a link to the warblers was reported in the 1950s by W. J. Beecher, who found a similarity in mandibular musculature between the larks and the *Cisticola* warblers. Be that as it may, the larks provide an excellent example of the caution which is necessary before more or less revolutionary taxonomic changes are adopted.

If the taxonomic affinities of the family remain unclear, still less is known about its internal groupings, despite the fact that much has been written on the subject. The fundamentally cryptic, dun-coloured plumages, lacking striking distinctive features, together with the variability of such characters as bill structure, have frustrated all attempts to identify subgroups on the basis of external morphology. Certainly, some groups are better defined than others. The sparrow-larks (*Eremopterix*), for instance, form a natural group, with marked sexual dimorphism and rather conservative plumage and morphology. Similarly, the crested larks (*Galerida*) are a well-defined group, the six members being characterized by similar displays and some morphological attributes. Relationships among the majority of larks, however, are poorly understood. The large genus *Mirafra*, in which up to one-third of all species were included in the past, is widely accepted as a "dumping ground" for a wide assortment of species, while some monotypic genera may not be sufficiently distinct to be justified; the single-species *Lullula*, for example, could be merged with *Alauda*.

Evidence from ongoing genetic-based studies of lark phylogeny allows the family to be restructured taxonomically. Data derived from mitochondrial-DNA sequencing provide a compelling argument for splitting certain elements from *Mirafra* and *Certhilauda* and resurrecting a separate genus, *Calendulauda*, for them. Unfortunately, not all species have been subjected to genetic sequencing, and in some cases, therefore, there is little alternative but to follow traditional practice. For example, species such as Gillett's Lark (*Mirafra gilletti*) and the Degodi Lark (*Mirafra degodiensis*) may well belong in *Calendulauda*, but for the present they are left in *Mirafra*. The genetic data strongly indicate that convergence has confounded previous phylogenies. For example, Gray's Lark (*Ammomanopsis grayi*), the small, plain-backed lark of gravel plains in the Namib Desert of south-west Africa, has traditionally been placed in the genus *Ammomanes*, along with the desert larks of north Africa and Asia, but genetic evidence clearly suggests that it is much closer to the morphologically quite distinct long-billed larks in the genera *Chersomanes* and *Certhilauda*. Accordingly, it is placed in its own genus, *Ammomanopsis*. The link to *Chersomanes* is intuitively appealing, because both occur in family parties throughout the year, and at least occasionally breed co-operatively, an unusual mating strategy among larks. The genetic data suggest that certain arrangements are not well supported. One example concerns Stark's Lark (*Spizocorys starki*), which many recent authors have placed with Dunn's Lark (*Eremalauda dunni*) in the genus *Eremalauda*, although the genetic evidence indicates clearly that it belongs within the broader group of *Spizocorys*. Unfortunately, no material from Dunn's Lark has been sequenced, and it remains uncertain, therefore, whether *Eremalauda* is a valid genus.

The mitochondrial DNA genes sequenced to date lack the power to resolve deeper relationships among lark genera. For example, the basal genus within the family varies according to the choice of outgroups and the analysis technique used. Intriguingly, in several analyses, *Heteromirafra*, the genus of peculiar short-tailed, big-headed larks with three highly localized species in south and north-east Africa, emerges as basal. Their very restricted and widely scattered ranges are suggestive of an old genus. Another contender that frequently emerges as basal is the Greater Hoopoe-lark (*Alaemon alaudipes*). A study aimed at resolving the deeper relationships within the Alaudidae, and employing more conserved nuclear genes, is currently being undertaken.

Mitochondrial genes have been useful in resolving species-level questions within the lark family. Although there has been considerable debate about the relationships among larks at both the species level and the genus level, even more has been written about the biological significance of geographical variation within

Traditionally placed in the genus Ammomanes, ***Gray's Lark*** *of the Namib Desert now finds itself the sole occupant of the genus* Ammomanopsis, *relocated far from* Ammomanes *in the taxonomic sequence. This shift in fortunes rests on the fact that, according to recent genetic analysis, the apparent similarity between Gray's Lark and the "desert larks" of North Africa and Asia is the result of convergence rather than common ancestry. Short bills and uniform pale upperparts are simply adaptations to life on level sandy or stony plains. Gray's Lark now appears to be more closely related to the longer-billed* Chersomanes *and* Certhilauda *larks, which seem very different morphologically.*

[*Ammomanopsis grayi grayi*, Swakopmund, Namibia. Photo: Andy & Gill Swash]

species. Cryptic species, or sibling species, appear to be widespread within the Alaudidae, and are very difficult to discern within the extensive geographical variation in plumage colour and pattern, linked to adaptation to local soil colour and vegetation density, that is shown by many lark species (see Morphological Aspects). A well-known case is that of the Thekla Lark (*Galerida theklae*) and the Crested Lark (*Galerida cristata*), which for long were confused with each other until C. L. Brehm separated them, in 1858. The vexing question has been that of how to differentiate intraspecific adaptation to local conditions from actual differences at the species level.

Lark taxonomy has followed the classic pattern of oversplitting, lumping, and resplitting of several species. The primary descriptive phase took place mostly during the nineteenth and early twentieth centuries, when many taxa were described as distinct species in accordance with a largely typological species concept. There was then a period of consolidation during the mid-twentieth century, when many taxa were lumped, following the biological species concept; at that time, the number of alaudid species generally recognized fell to about 75. Recent studies have tested the validity of some of these polytypic species by using a diversity of evidence, including vocalizations and reanalysis of morphology, as well as genetic-sequence data. The results have been varied, but, in general, the genetic data have often revealed significant variation among "subspecies", indicating that such taxa have had separate evolutionary histories for perhaps between one million and five million years, as estimated from cytochrome *b* gene divergences of 2-10%. The number of lark species currently recognized has already risen to nearly one hundred.

In some instances, these latest genetic studies have resulted in the original, morphologically based species being upheld and new taxa being "discovered". In the "long-billed lark complex" of southern Africa, for example, genetic evidence led P. G. Ryan and P. Bloomer to support the recognition of three of the four morphologically defined species originally proposed by A. Roberts in the 1930s: the Cape Long-billed Lark (*Certhilauda curvirostris*), the Karoo Long-billed Lark (*Certhilauda subcoronata*) and the Eastern Long-billed Lark (*Certhilauda semitorquata*). It also suggested, however, that two additional species should be recognized. One of these, the Agulhas Long-billed Lark (*Certhilauda brevirostris*), is quite distinct both morphologically and vocally, but the other, the Benguela Long-billed Lark (*Certhilauda benguelensis*), is rather poorly defined in terms of morphology, although, admittedly, it has not been well studied. In a similar investigation, P. Alström found that the "*Mirafra assamica* complex" contained four cryptic species that had hitherto been treated as conspecific; these are the Bengal Bushlark (*Mirafra assamica*), Jerdon's Bushlark (*Mirafra affinis*), the Indochinese Bushlark (*Mirafra erythrocephala*) and the Burmese Bushlark (*Mirafra microptera*).

Nevertheless, not all forms originally described as full species can be maintained as such. In the Karoo Lark (*Calendulauda albescens*) complex of forms living in western South Africa, Roberts considered that the marked change in plumage colour, from pale grey-brown on the whitish coastal sands to rich rufous on the reddish interior sands, warranted the separation of the two populations at the species level; he referred to the pale coastal form as "*C. albescens*" and the rufous interior form as "*C. guttata*". Indeed, the borderline between these two colour morphs is extremely marked, the plumage colour often changing completely within a distance of a few kilometres, and with very few intermediate individuals entirely confined to the transitional zone. In the terms of the phylogenetic species concept, it could be argued that this is a character separating two "species", but, conversely, there is no genetic difference between the two populations, and they share the same morphology and songs. Clearly, in this case, the two are best treated as conspecific, with different subspecies names as convenient labels to describe the observed variation. Interestingly, the same colour switch, from pale to rufous, occurs also in Barlow's Lark (*Calendulauda barlowi*), recently split from the Karoo Lark, which it replaces geographically in the north.

To date, only a few species complexes have been studied by adopting an integrated approach incorporating vocal, morphological and genetic evidence. What can be learnt from these studies? Probably, there are not any general rules, other than that further investigation is likely to result in the recognition of many more lark species, in the sense of evolutionary entities. These "new" species are most likely to be identified among resident species that exhibit high levels of regional variation. Probable candidates in this category include the Crested and Thekla Larks, several of the isolated African populations of which are quite distinctive, as well as the Rufous-naped Lark (*Mirafra africana*).

Most members of the family are dull, dun-coloured birds, predominantly brown or fawn in tone, always paler or even white below. Their earthy tones and counter-coloration provides camouflage in open terrain, where they tend to be well lit from above. In general, the colour of lark upperparts matches the colour of the substrate where they live. Thus, the pallid ***Dunn's Lark*** *lives in pale sandy deserts, whereas the* ***Rufous-tailed Lark*** *lives against a darker background. Even within a given species, mantle colour varies in different parts of the range according to the colour of soils and sands. In general, lark plumage comes in two types. One is variegated and thus camouflaged on broken terrain. Another is uniform and thus camouflaged only where the background is relatively smooth. These two species are of the latter variety. They have the stubby, conical bills typical of granivorous species, with that of the monotypic genus* Eremalauda *being especially blunt-tipped. The more insectivorous larks tend to have relatively slender, sharp or decurved bills. There is also a relationship between bill shape and substrate, with stubbier-billed species usually being birds of harder or rockier ground, and longer-billed species usually living in sandy environments.*

Below: *Ammomanes phoenicura*, Kachchh, Gujarat, India. Photo: Otto Pfister]

Although larks in general are cryptic, some species are much more boldly marked than others. The most piebald patterning is found in members of the genus Eremopterix, *such as the* ***Black-crowned Sparrow-lark****. The sparrow-larks are the only members of the family to exhibit notable sexual dimorphism, males being much more ornate than their dowdy partners. Another genus of boldly patterned larks is* Eremophila, *both members of which have black elongated feathers on either side of the hind crown. These "horns" are much less prominent in females, allowing us to identify this* ***Temminck's Lark*** *as a male. Despite the striking plumage of* Eremopterix *and* Eremophila, *they are often surprisingly well camouflaged, especially as they crouch whenever there is cause for alarm.*

The genus Pinarocorys *contains two species which, were it not for their odd structure, sexual dimorphism and migratory habits, might otherwise be placed in* Mirafra. *Both have striking facial patterns and boldly marked breasts. One of them, the* ***Dusky Lark****, is pictured here in the open country of its wintering range; it breeds in burnt areas in miombo woodland. Due to its bulk and its habit of perching in trees, this species is perhaps more often mistaken for a Groundscraper Thrush* (Psopocichla litsipsirupa) *than any other species of lark. It even looks rather thrush-like in flight.*

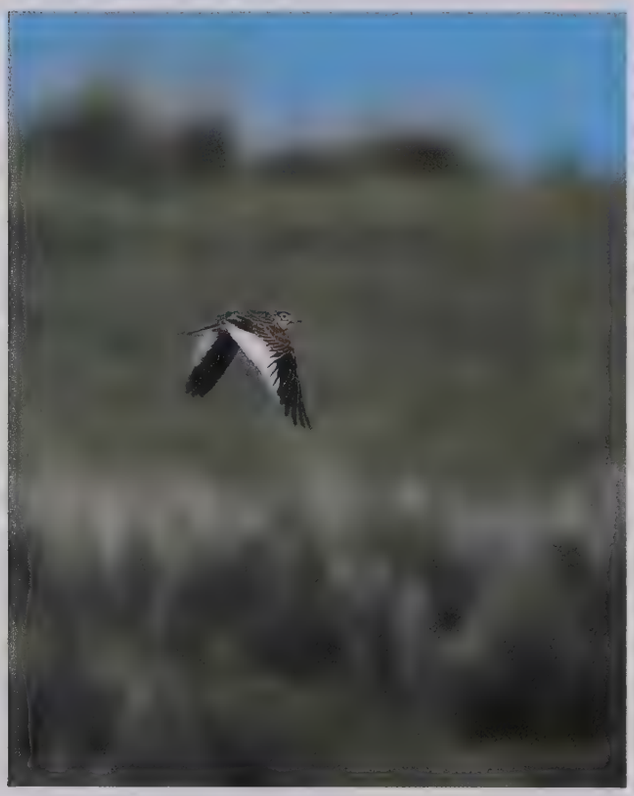
[*Pinarocorys nigricans*, South Africa. Photo: Roland Seitre]

Judging from the distribution of the living species, it seems clear that the evolutionary origins of the Alaudidae were in Africa. Not only do 78, over 80%, of the 96 currently recognized species occur in Africa, but 60 of those are found nowhere else. Eurasia has 36 species, 17 of them endemic. The proportion of species that are endemic to each continent therefore reaches 77% in Africa and 47% in Eurasia. In addition, those species which are not exclusive to one of these two landmasses tend to be shared by both of them. The sole species to have reached the New World, the Horned Lark (*Eremophila alpestris*), extends widely throughout North America south to southern Mexico, and has a very interesting disjunct presence in South America, in the Andean Altiplano near Bogotá, in Colombia. This species, however, is very far from being exclusively American. On the contrary, it has the widest global distribution of any alaudid, being the only one to occupy boreal latitudes and, moreover, extending south in Eurasia through mountain chains from the Moroccan High Atlas to the Himalayas. The only other species occurring outside the strictly African-Eurasian distribution are the Madagascar Lark (*Mirafra hova*), restricted to Madagascar, and the Australasian Bushlark (*Mirafra javanica*), which extends from South-east Asia and the Philippines through Indonesia and New Guinea to Australia. It is clear, therefore, that the larks are principally an African and secondarily a Eurasian family. Their presence in the Americas and Australia is exceptional, and perhaps of relatively recent origin: given the extent and diversity of arid ecosystems there, one might have anticipated a much stronger representation of alaudids.

Larks are resident on numerous islands which either lie near continents, as in the case of Madagascar, or have been joined to the mainland in past epochs when sea-levels were lower, as applies to many of the islands occupied by the Australasian Bushlark. Japan is home to the endemic subspecies *japonica* of the Eurasian Skylark (*Alauda arvensis*), and the family is represented in Taiwan, on Hainan, in Sri Lanka, in the British Isles and on many other islands. All of the major Mediterranean islands hold larks, and several species are present on some of them, there being five breeding alaudids in Crete and Sicily, for instance. As is often the case with island avifaunas, however, there are conspicuous absences of certain species which are common on the nearby continental mainland; for example, on the Balearic Islands, adjacent to the Iberian Peninsula, only the Thekla Lark and the Greater Short-toed Lark (*Calandrella brachydactyla*) breed. The latter species, certainly, is the most widely distributed among the Mediterranean islands, whereas the Lesser Short-toed Lark (*Calandrella rufescens*) is absent from all of them, although the geographical ranges of the two species are otherwise similar. No doubt, the Greater Short-toed Lark, a more migratory species, is better able to colonize islands than is the Lesser Short-toed Lark, which is sedentary. Even so, it is curious that in the Canary Islands, where the former appears frequently on passage, the sole breeding lark species is the Lesser Short-toed Lark. Other noteworthy cases of insular occupation by larks include the island of Socotra, some 250 km from the coast of Somalia, which is inhabited by the Black-crowned Sparrow-lark (*Eremopterix nigriceps*), and the Faeroes, 350 km north of Scotland, which have the Eurasian Skylark. Particularly remarkable is the Cape Verde Archipelago, which lies some 500 km off the African Atlantic coast, and where up to four lark species breed; these are the Greater Hoopoe-lark, the Bar-tailed Lark (*Ammomanes cinctura*), the Black-crowned Sparrow-lark and the Raso Lark (*Alauda razae*), this last having a global range that is confined to just one tiny island of the archipelago.

The distribution of lark species within Africa is far from uniform. There are two "hot spots" of diversity, corresponding to the arid zones of the north-east and of the south-west. The former, which is centred on Ethiopia and Somalia, holds no fewer than 37 species, of which 62% are endemic. The south-western centre corresponds with the deserts and semi-deserts of Namibia, Botswana and South Africa and has 33 species, 85% of which are endemic or near-endemic. Many of the endemics of both these zones are extremely limited in geographical distribution and, for that reason, some of them are among the most vulnerable of all alaudids, although their arid habitats tend to place them under less pressure than is faced by species occupying habitats with greater agricultural potential (see Status and Conservation). These two arid regions are home to a combined total of 65 species, approximately 83% of the African total and 68% of the world's lark species. Bearing in mind that the lark family is essentially adapted to open, arid regions (see Morphological Aspects, Habitat), there would seem to be merit in the hypothesis, perhaps first formulated by R. E. Moreau, that links the high levels of species diversity and endemism to the finding that the aridity of these

*The steppes of Central Asia are home to one of the most distinctive members of the family: the **Black Lark**. Other* Melanocorypha *larks have small patches of black on the plumage, but this one takes melanism to the extreme. The male moults into fresh brown plumage in autumn, but in spring the tips of these feathers abrade, revealing his black breeding dress. This plumage signal must at times be costly, as it renders the male very poorly camouflaged in comparison with the drab female. In flight, he looks long-winged and almost starling-like.*



[*Melanocorypha yeltoniensis*, Kazakhstan. Photo: Tim Loseby]

two corners of Africa is of long standing. As may be supposed, both zones also hold numerous other endemic open-country avian species of believed Afrotropical origin, such as bustards (Otididae), sandgrouse (Pteroclidae), coursers (*Cursorius*), wheatears (*Oenanthe*) and cisticolas. It is, however, in the Alaudidae that both the highest number and the largest proportion of endemic species are found.

These two African zones of maximum lark diversity are currently completely isolated from each other, but they may well have been linked during interpluvial periods of the Pleistocene by a corridor of arid territory through the east of the continent, passing through present-day Kenya, Tanzania, Zambia and Zimbabwe. This would perhaps explain the current existence of species pairs in which the partners are of very closely related ancestry but are now separated geographically by thousands of kilometres, comprising what are termed vicariant species in biogeography. Such cases exist in various bird groups, but the Alaudidae provide excellent examples in the species pairs formed by the Chestnut-headed Sparrow-lark (*Eremopterix signatus*) of the north-east zone and the Grey-backed Sparrow-lark (*Eremopterix verticalis*) of the south-west zone and, equally, by the north-eastern Archer's Lark (*Heteromirafra archeri*) or Sidamo Lark (*Heteromirafra sidamoensis*) and the south-western Rudd's Lark (*Heteromirafra ruddi*). The existence of an arid corridor of this kind could likewise explain the various other instances of vicariance between larks of northern and southern Africa, such as that seen in the two species of *Pinarocorys*, the northern Rufous-rumped Lark (*Pinarocorys erythropygia*) and the southern Dusky Lark (*Pinarocorys nigricans*). For most species pairs for which data are available, however, the magnitude of genetic differences are substantial, suggesting that the taxa in question became isolated from each other during the Pliocene, rather than during the more recent Pleistocene.

Larks are typical inhabitants of the north African deserts. None of the species, however, is exclusive to this region, and the lark community does not have the level of species diversity of the aforementioned zones. Thus, the distributions of the most typically Saharan alaudids, including the well-known Desert Lark (*Ammomanes deserti*), Thick-billed Lark (*Ramphocoris clotbey*) and Greater Hoopoe-lark, extend across the adjacent deserts of south-west Asia, helping to define the boundaries of the Saharo-Sindian region, the belt of arid lands which extends from the Maghreb, in north-west Africa, eastwards to the Sind and other deserts of Pakistan and north-west India. Larks comprise roughly one-fifth of all the bird species of this region.

In Eurasia proper, two zones stand out for the diversity and levels of endemism of their lark communities. The cold deserts of the Caspian-Mongolian region, in the centre of the continental landmass, hold at least 15 species, nearly half of which, comprising five *Melanocorypha* and two *Calandrella* species, are found nowhere else. The Oriental Region, in the south, contains 23 species of alaudid; ten of these, including five *Mirafra* bush-larks, two *Galerida* species, and one representative of each of

*Although most larks are cryptic when perched, many species have bolder patterns on the wings or tail which become visible in flight. Pale outer tail feathers, or pale trailing edges to the wings, are common features, though few bear these badges as strikingly as the **Mongolian Lark**. The prize for the most dramatic wing pattern in the family, however, must go to the **Greater Hoopoe-lark**. These patterns possibly distract predators, and certainly function as signals of identity or individual quality.*

The ability to hover for prolonged periods during song flights is an important sexually selected trait in male larks. Some species are relatively immobile during these hovering displays, but others, such as the ***Greater Short-toed Lark****, slowly circle, meander or undulate. Although males of this species usually hover 30-50 m up, some species display so high above the ground that they are very difficult to see with the naked eye. Male larks of several species regularly spend up to ten minutes hovering in this way, which must represent a major energetic outlay, before plummeting steeply back to earth.*

[*Calandrella brachydactyla brachydactyla*, Greece. Photo: Tomi Muukkonen]

the genera *Ammomanes*, *Eremopterix* and *Calandrella*, are restricted to this region. By comparison, Europe has very little to offer in terms of lark diversity, which is hardly surprising when one considers its marginal position on the Eurasian landmass, its relatively limited extent and, above all, its generally temperate and wet climate, which is unsuited to such birds. Only three members of the family are widely distributed in Europe, these being the Eurasian Skylark, the Woodlark (*Lullula arborea*) and the Crested Lark. More occur around the Mediterranean Basin, with five species on the Italian peninsula, six in the Balkans and eight in Iberia, all of them shared with northernmost Africa. The south-eastern part of European Russia, adjacent to Kazakhstan, has ten species. Both here and in Iberia, the diversity of larks and their prominence within the passerine community increase gradually in a south-easterly direction, in tandem with the increasing aridity of the terrain.

Morphological Aspects

As passerines go, the larks are neither particularly large nor especially small, ranging in size from that of a finch to that of a Common Starling (*Sturnus vulgaris*). Body length ranges from approximately 10 cm, as with some female sparrow-larks in the genus *Eremopterix*, to 23 cm in the case of the largest males of the relatively elongated Greater Hoopoe-lark. The sparrow-larks may weigh as little as 12 g, whereas the Tibetan Lark (*Melanocorypha maxima*) can reach at least 75 g. Within any species or subspecies, weight is, of course, highly variable, being dependent at least in part on food resources and the time of the year. In some species, such as the Woodlark and the Crested Lark, the sexes do not differ appreciably in dimensions. For the majority of the alaudids, however, the males are significantly the larger sex, with mean weights up to 20-25% greater than those of the females. Because of this, it is sometimes possible, with practice, to distinguish in the field between the males and females of lark species that are not sexually dimorphic in plumage. In the southern African alaudids, at least, this sexual size dimorphism may be related to feeding habits, as it is more evident in the most insectivorous species, such as the Spike-heeled Lark (*Chersomanes albofasciata*), than in the more granivorous ones.

Among the passerines, the larks do not stand out as having any striking body proportions. In general, they are relatively robust, large-winged and moderately long-legged. The toes and front claws are relatively short. The hind claw, however, is variably long, straight and narrow, sometimes markedly so, recalling that of other terrestrial passerines such as the pipits (*Anthus*) and longclaws (*Macronyx*) of the family Motacillidae, or the longspurs (*Calcarius*) of the family Emberizidae. Attempts have been made to relate the variation in hind-claw size to the substrate used by each species, but it is odd that short-curved hind claws are found in species such as the Desert Lark and the Greater Hoopoe-lark, which inhabit sandy deserts, and long straight ones in larks of other habitats, for example in the Eurasian Skylark and the Woodlark, the latter being typical, as its name suggests, of fairly wooded terrain. It is possible, although the available information is insufficient to demonstrate it, that there may be a relationship between hind-claw size and the extent to which a species runs, for it could be expected that all claws, including the hind claw, would be shorter and stronger in those species which are capable of fast running, among which the very long-legged Greater Hoopoe-lark is pre-eminent. This species is said to be able to run for extended periods at a speed of 8 km/h.

All larks move with agility on the ground, whether walking or running, and some, such as Dupont's Lark (*Chersophilus duponti*), prefer to run rather than to fly when avoiding terrestrial predators or human observers. Moreover, there seems to be a correlation between leg length and diet: the more insectivorous species have longer legs and are better runners than the specialist seed-eaters, which have relatively short tarsi. This difference would seem to be adaptive, longer legs enabling better running ability when chasing insects and short legs being more suited for the behaviour of searching for small seeds on the ground.

Larks are sometimes seen to hop, especially as juveniles during their first days after leaving the nest; indeed, young Horned Larks hop during nearly the whole of their first month out of the nest. This may indicate that this style of locomotion is more ancient phylogenetically than is walking. In addition, Thick-billed Larks frequently hop, and hopping features in the courtship displays of several species.

The Alaudidae have ten primaries, but the outermost, the tenth when the feathers are numbered descendantly, is very vari-

*This **Greater Short-toed Lark** is immediately identifiable as a juvenile because it is distinctly mottled. In comparison with adult larks, juveniles tend to have paler fringing or tipping to the feathers of the upperparts and crown, and any striking features are usually dull or absent. This all helps to ensure that, for the first 4-6 weeks at least, young birds are well camouflaged. During these early days juveniles usually hop, before they learn to run like adults. Seed-eating larks, such as those in the genus* Calandrella, *tend to have relatively short legs, while insectivorous larks are longer-legged, and thus better adapted for running at high speed.*

[*Calandrella brachydactyla brachydactyla*, Corella, Navarre, Spain. Photo: José Antonio Martínez]

able in development. It is practically vestigial in some genera, as in *Melanocorypha* or *Calandrella*, yet in others it extends well beyond the tip of the longest primary covert, as occurs in *Ammomanes* and *Alaemon*. It seems that, in general, a long tenth primary is associated with short, rounded wings, such as those possessed by the more sedentary species. Hence, it has been hypothesized that the longer, narrower wings of long-distance migrants have evolved from the earlier arrangement, the reduction of the tenth primary being a part of this process. The idea that the short tenth primary may be derived from a longer antecedent may also be supported by the fact that these small feathers are longer and wider in juveniles than in adults. As an example, the tenth primary of the adult Eurasian Skylark falls 10-17 mm short of the tips of the primary coverts, whereas that of the juvenile is between 6 mm shorter and 1 mm longer in relation to the covert tips. Similarly, the narrow and pointed outer primary of the adult Thick-billed Lark falls 4-12 mm short of the primary-covert tips, but the round-tipped outer primary of the juvenile varies in length from almost reaching the tips of the primary coverts to extending 2 mm beyond them. There are many comparable examples within the family.

Differences in wing formula are often very useful in distinguishing between species which are otherwise very similar in appearance. The Oriental Skylark (*Alauda gulgula*), for instance, has the sixth primary 0-6·5 mm shorter than the longest primary, whereas the corresponding figure for the more migratory races of the Eurasian Skylark is 4-13 mm. It is, however, interesting to note that, in the more or less sedentary race *japonica* of the latter, the sixth primary is only 2-8·5 mm shorter than the longest one.

Overall, and taking weights into account, male larks have larger wings than females. This may be adaptive in respect of the male's extended song flights, the high energy costs of which may be mitigated by its having a reduction in wing-loading, that is, in mass supported per unit wing area (see Voice). When migratory and sedentary species are compared, the former are seen to have narrower wings, and hence higher wing-loadings, than the residents, a fact which was noted with surprise by R. Meinertzhagen. In pairwise comparisons of lark species of similar sizes, the migratory Greater Short-toed Lark has a wing-loading of approximately 0·34 g/cm², as opposed to the 0·26 g/cm² of the sedentary Desert Lark; similarly, the Calandra Lark (*Melanocorypha calandra*), a partial migrant, carries 0·32 g/cm², compared with the 0·15 g/cm² of the Greater Hoopoe-lark, a sedentary or, at best, dispersive species. In fact, among birds in general, narrow wings and high wing-loading are associated with fast flight, which is probably of particular value to long-distance migrants.

Strikingly long tertials are a feature of alaudid wings. On larks, as on pipits and wagtails, the tertials cover all of the primaries when the wings are closed, or they allow at most only the tips of a few to be exposed. This cloaking may protect the primaries from abrasion, something which is likely to be especially useful to such terrestrial birds, a consideration which applies to the Motacillidae as well as to the Alaudidae. Lark tertials do, indeed, habitually exhibit a high degree of wear.

Diverse species, among them the Eurasian Skylark, the Greater Short-toed Lark and the Rufous-naped Lark, have a crest composed of a group of longer, erectile head plumes, which the birds raise when excited. In the crested larks in the genus *Galerida*, these crests are long, pointed and permanently raised. The two species of *Eremophila*, the Horned Lark and Temminck's Lark (*Eremophila bilopha*), sport a different type of head adornment in the shape of two little "horns", comprised of long, black, pointed feathers forming upright tufts on each side of the hindcrown, which are particularly prominent on males.

As part of this family's general adaptation to open terrain, lark plumages are always cryptic, predominantly brown or fawn in tone, darker above and paler, sometimes almost white, below. Two types of plumage pattern have been identified, and G. L. Maclean has termed these, respectively, "generalized" and "specialized". The first type, which is exhibited by most species, is distinguished by having a mixture of colours, often with dark streak-shaped or spot-shaped feather centres set against a more or less buff background. The specialized type is more uniform, and involves a close colour match with the background tones of the birds' habitual terrain. Very pale, sandy-desert tones are frequently found in this second type, but rufous, greyish or blackish tones often occur also. The generalized type provides camouflage which is effective in nearly any type of terrain, but the specialized type is effective only where there is a perfect colour match between ground and plumage. It is not surprising, therefore, that, as has been noted in southern Africa, migratory or nomadic larks have generalized cryptic plumages and sedentary species display

Like other passerines, larks are equipped with strong feet, and they perch on twigs with ease. Nonetheless, many species spend most of their life on the ground. When disturbed, the ***Crested Lark****, like other members of the genus* Galerida*, usually flaps away, with its distinctly rounded wings giving it a very characteristic look. Nine times out of ten it will drop back down to the ground, but in this case it has chosen an elevated perch. The hind claw in larks can be very long, as it is in other terrestrial passerines, such as the pipits and wagtails (Motacillidae), and its precise form is probably connected with the normal mode of movement of each species, although to date this remains largely a matter for speculation. Much more conspicuous in this photo is the crest which gives this particular species its name. Many larks, especially those in the genera* Alauda *and* Galerida*, possess erectile crests which they raise when excited or alarmed. None is longer, or used more frequently, than that of the Crested Lark. Across its extensive range this species occurs in a variety of habitats, but typically in dry, dusty or grassy plains, generally with fairly sparse vegetation. It also occurs in semi-desert, but in other areas frequents biotopes heavily modified by the activities of man, especially farmland.*

[*Galerida cristata iwanowi*, Badkhyz Nature Reserve, Turkmenistan. Photo: Gertrud & Helmut Denzau]

All larks are associated with more or less open habitats. Of these, natural grasslands are important, whereas other types of grassland, such as lawns, pastures and cultivation, are less popular. These man-modified habitats have found most favour with members of the genus Alauda, *including the* ***Oriental Skylark****. This species can breed and winter in cultivated fields or grazing lands, but it also favours the margins of wetlands. One of its diagnostic features is shown very clearly in this photograph: the largest tertial almost entirely cloaks the primaries, whereas the primaries project much further beyond the tertials in the Eurasian Skylark* (Alauda arvensis).

[*Alauda gulgula*, Oman. Photo: Markus Varesvuo]

the specialized type. In the Kalahari sandveld, for example, the sedentary larks of the reddish sand dunes, such as the Eastern Clapper Lark (*Mirafra fasciolata*), have rufous plumage tones and those inhabiting areas of grey calcrete soils are themselves greyish, as is demonstrated by the Grey-backed Sparrow-lark. Further, the intensity of dark streaking of the dorsal plumage has a clear correlation with the extent of plant cover, at least in Africa, where the darkest and most densely streaked species are those living in the most vegetated habitats.

Much discussion has centred on the function, or functions, of "desert coloration" among the Alaudidae. That it has the role of an anti-predator device is well supported, and the birds' own behaviour provides some of the best evidence to confirm this. It has long been known that individuals of a given colour endeavour to avoid switching to sites where they would be more conspicuous. In Jordan, for example, two races of the Desert Lark live side by side. One of them, *coxi*, is pale and the other, *annae*, which inhabits lava desert, is very dark. It has been reported that it is impossible to displace the dark larks on to pale terrain or to drive the sandy larks on to the dark lava. This specialization in coloration, which is linked to a sedentary existence and is perhaps reinforced by strong philopatric tendencies, favours reproductive isolation and the resultant emergence of subspecies, which would explain in large measure the considerable interspecific differences in the extent of subspeciation in the Alaudidae (see also Systematics). It is interesting to compare, for example, the congeneric Desert Lark and Bar-tailed Lark, species of similar sizes and distributions, the former having 24 subspecies but the latter only three. This difference may be related to their habitat preferences: the Desert Lark inhabits stony and rocky areas, where the ground colour varies greatly with rock type, whereas the Bar-tailed Lark lives in sandy desert, where the ground colour is far less varied.

It should be noted, nonetheless, that some alaudids have a plumage basically of the generalized, cryptic type, but also occur as numerous subspecies. The Crested and Horned Larks are two such examples. These are species with very wide geographical distributions, and which are migratory in the most northerly parts of their ranges but sedentary elsewhere. Their different races exhibit highly variable amounts of streaking. Thus, in the north there are few subspecies, heavily streaked but similar in plumage over extensive areas, while in the south there are many subspecies, all of which show little streaking, or almost none at all, and have a ground colour which closely matches that of the terrain. This near-absence of streaking in southern subspecies is well demonstrated by the Saharan race *arenicola* of the Crested Lark and the Californian desert race *ammophila* of the Horned Lark.

The plumage of larks often includes areas of contrasting coloration. These parts are typically black and white, but are sometimes rufous, as in the wings of the Red-winged Lark (*Mirafra hypermetra*), or yellow, as on the head of the Horned Lark. Such areas are generally of limited extent, however, and very often they are hidden in the wings and tail and are visible only when the bird takes flight, and so they do not otherwise disrupt the species' normal camouflage. Markings of this sort tend to be used for communication; they function as alarm signals, in species recognition and probably also as indicators of individual fitness, this last involving the degree to which they are well defined and symmetrical. Notable display markings include wing patterns, which are especially striking in the Greater Hoopoe-lark and the White-winged Lark (*Melanocorypha leucoptera*), and frequently tail patterns, as seen on, for example, the Bar-tailed Lark and Gray's Lark. Many members of the family have blackish or black wings and tail, which emphasize the white tail borders or outer rectrices. Such patterns tend to be more noticeable when seen from below, a phenomenon which may be connected with the high-level song flights characteristic of larks. In some cases, black and white marks occur on the head, as with the Thick-billed Lark and the Masked Lark (*Spizocorys personata*), and in others they are present between the neck and the breast, as with the Calandra Lark and the Collared Lark (*Mirafra collaris*). Exceptionally, and in the few species which are sexually dimorphic in coloration, such markings cover more extensive areas. This is the case with the Thick-billed Lark, with the seven species of sparrow-lark, the males of which are black on much of the head and ventral areas, and with the Black Lark (*Melanocorypha yeltonensis*), in which the male is basically black and the female dark brown. It is worth pointing out here that, while the markings of male sparrow-larks may seem conspicuous in illustrations, they are certainly not so in the field; this is partly because the head markings provide disruptive camouflage by breaking up the bird's silhouette, and

Certain species in the genera Galerida *and* Melanocorypha *are very partial to grasslands, usually preferring relatively close-cropped vegetation. In Africa, the* ***Large-billed Lark*** *occurs in a wide variety of grasslands, including rocky uplands with a short sward, as here, and longer-sward pastures in the lower foothills. It also occurs in the South African wheat-belt, where it is especially fond of ploughed fields. In all these habitats it forages for grain and seeds, and uses its robust beak to dig in the ground for small bulbs. In Asia, the* ***Tibetan Lark*** *inhabits high-altitude grasslands in the western Himalaya, where it is found around marshes and bogs on the Tibetan Plateau. Not only is this species one of the largest of all larks, weighing up to 75 g, but it lives at higher altitudes than almost all its relatives, having been recorded 4600 m above sea-level.*

partly because the ventral black areas correspond to parts of the bird's body which are normally in shadow.

Juvenile larks tend to differ in plumage from adults. Typically, they have a mottled appearance resulting from pale feather edging on the crown and back, and any contrasting marks either absent or poorly defined. This first plumage is short-lived, lasting for only a month to six weeks. It is followed by a complete post-juvenile moult that includes even the flight-feathers, something which is relatively infrequent among passerine birds. Adults have a single complete moult which takes place after breeding, in early summer in the Northern Hemisphere, and lasts for a couple of months. The primaries are shed descendantly, commencing with the innermost. In general, this is the sole annual occasion of plumage renewal. Changes in appearance in spring, which are often rather marked, result from wear of the contour plumage, the Black Lark providing a striking example. There is, however, one subspecies of the Greater Short-toed Lark, *dukhunensis*, a native of Tibet and central China, for which a partial moult affecting the body and upperwing-coverts has been described. It is certainly surprising that, within a species, albeit one with many races, there should be just one subspecies which departs from the general moult pattern. An explanation may be found in the particularly windy and abrasive conditions of the desert areas which it inhabits. Two annual moults have also been described for three larks of the Namib Desert of south-west Africa, namely Gray's Lark, Stark's Lark and the Grey-backed Sparrow-lark, although, unlike the previous example, both are complete moults; the usual moult is quite rapid and takes place after breeding, when the birds take advantage of the good food supplies following the rains, but the second is prolonged throughout the dry season. In these instances, too, the double moult is explained as an adaptation to the rapid wear of plumages which are exposed to wind, sand and the desert sun.

In general, it is certainly the case that recently moulted lark plumages tend to change appearance very rapidly, owing to bleaching and abrasion. This fact has in the past complicated and, sometimes, confounded taxonomic studies, as the recognition of subspecies depends on the availability and comparison solely of fresh-plumaged specimens.

A final aspect of lark morphology which cannot be overlooked is that of the bill, which is extraordinarily variable. As is logical, this huge variability is very closely related to the different feeding habits of the members of the family (see Food and Feeding). No other passerines, with the notable exceptions of the vangas (Vangidae) of Madagascar, "Darwin's finches" (Geospizinae) of the Galapagos Islands and the Hawaiian honeycreepers (Drepanididae), provide a better example of adaptive radiation with regard to this feature of morphology. Those alaudids which consume the greatest quantities of invertebrates possess a long, fine bill, often somewhat decurved, and sometimes specialized for unearthing insects and their larvae from sandy ground. The bill of the Greater Hoopoe-lark, at some 3 cm in length, is longer than the rest of the bird's head, and that of the Spike-heeled Lark and various *Certhilauda* larks is also noteworthy in this respect and is associated with soft substrates. In this context, an apparent relationship between the hardness of the ground and the comparative abundance of each species has been reported for the two *Galerida* larks found in north Africa: the longer-billed Crested Lark is more common on softer terrain and the shorter-billed Thekla Lark predominates on harder ground. Dupont's Lark, nevertheless, has a long, somewhat curved bill, but prefers firm substrates to sandy ones; this may be explained by its specialized feeding habits, since a large part of its diet, or at least that of the chicks, consists of ground-living spiders which the birds must extract from deep holes in the soil.

At the other extreme is the short, often conical and robust beak which is characteristic of the most granivorous genera, such as *Eremopterix*, *Spizocorys* and *Calandrella*, and which reaches its greatest development in the aptly named Thick-billed Lark. The latter's bill is some 13 mm deep at the base and about 20 mm long, both mandibles being strongly curved and reminiscent of the beaks of certain finches and buntings. Curiously, though, the mandibular musculature may not amount to much, judging from the weakness of the pecks delivered by individuals held in the hand.

A very interesting aspect of bill morphology concerns the sexual dimorphism which seems to exist in species such as the Spike-heeled Lark and the "long-billed" group, in which males have a relatively larger bill than do females. This difference is considerable in the case of the Raso Lark, the bill of the male being some 25% longer than that of the female, which is reflected in the observation that foraging males spend relatively more time

Most larks avoid active cultivation because crops quickly grow too tall for their taste. However, they are often attracted to agricultural land after harvesting because of the fallen grain and other food items to be found in stubble fields. They are also keen on ploughed areas where the soil has been turned over, and fallow areas where wild grasses are left to seed. Like many of its relatives, ***Erlanger's Lark*** *often visits these habitats, sometimes in large flocks, to take advantage of the rich food supply. Here it is pictured foraging on the dark soils of recently ploughed land in the Ethiopian highlands.*

[*Calandrella erlangeri*, Sululta plain, Ethiopia. Photo: Göran Ekström]

probing for food and less time turning over pebbles. The fact that the two sexes forage as if they were different species must have adaptive significance, probably permitting these birds to exploit more fully the limited resources of their living quarters, a tiny island in the Cape Verde Archipelago.

Habitat

Over their extensive geographical distribution, larks occupy a great diversity of habitats. They are found in African savannas, Asian steppes, Mediterranean scrub, Eurosiberian pastures and high mountain zones, among others, but most of them live in arid or semi-arid zones, such as deserts, steppes, savannas and thin scrub, where the annual precipitation ranges between 100 mm and 800 mm. In all these cases they occur in open, structurally simple environments which offer only low vegetation or, in a few instances, scattered trees, and which have a large amount of bare ground or areas of short grass, which allows them to search on foot for insects or seeds. Habitat selection by alaudids is also greatly influenced by relief, with flat or gently undulating areas being preferred, although some species, such as the Desert Lark, occupy rocky slopes. Larks tolerate climatic conditions ranging from those of extreme desert, with less than 50 mm of annual precipitation and temperatures which may exceed 50°C, as experienced by the Greater Hoopoe-lark, to very cold conditions, as occur in many of the northern and alpine regions inhabited by the Horned Lark.

Although many species nest at sea-level, others do so at high elevations. Thus, in Asia, the Bimaculated Lark (*Melanocorypha bimaculata*) occurs at altitudes between 1600 m and 2700 m, the Tibetan Lark reaches 4600 m in the western Himalayas, and Hume's Lark (*Calandrella acutirostris*), one of the most noteworthy examples, often breeds at or above 5000 m in Tibet. The Horned Lark ascends even higher, nesting up to the snow-line, at 5400 m, in the Himalayas. In Africa, the Large-billed Lark (*Galerida magnirostris*) is common above 3000 m in Lesotho, and it is not unusual to see the Horned Lark above 3000 m in the High Atlas of Morocco. The latter species exhibits a high degree of flexibility in its habitat choice in North America, perhaps because other larks are absent there; it can be found living from sea-level up to altitudes of 4000 m, and in regions varying from very dry ones, which receive less than 100 mm of annual precipitation, to very wet ones with over 1000 mm annually. The upper altitudinal limits of widely distributed northern species, such as the Horned Lark, tend to rise in the more southerly parts of their ranges, and this may be evident over quite short distances. In the Iberian Peninsula, for example, over a distance of barely 700 km from north to south, the Eurasian Skylark can be found nesting at sea-level in the north, mainly at 600-1200 m in the central tablelands, and only on mountain tops in the south, where it reaches 3500 m in the Sierra Nevada.

So, which habitats are particularly favoured by the Alaudidae? Certainly, the predilection of many larks for arid environments is well known and is reflected in the scientific names of various genera, in which combinations of the Greek words *chersos*, *eremos* or *ammos*, which refer to deserts or wastelands, and *philos* or *manes*, which indicate a liking or preference, appear. The available information shows that approximately three-quarters of the Afrotropical species, the most diverse assemblage, reproduce in such habitats, whereas only about a tenth occur in a wide range of habitats and scarcely a further tenth inhabit humid pastures. Among the north African breeding species, nearly half are associated with arid or semi-arid habitats, the remainder being equally divided between those which occur in a broad range of habitats and those which choose moist or fairly humid pastures.

Within this general pattern, different species respond in very diverse ways to a series of environmental factors, notably aridity, vegetation structure and the colour of the substrate. The effect of aridity on species composition in a lark community may be appreciated, for example, on the high plateaux of Morocco and Algeria, a region which is flat or undulating, of uniform altitude and without geographical barriers, but where there is a marked gradient of precipitation between the Mediterranean Sea and the Sahara. Here, ten or so species can be encountered over a distance of barely 200 km, among them the Eurasian Skylark and Dupont's Lark, which predominate in the rainiest zones, and Temminck's Lark and the Greater Hoopoe-lark, which are most frequent in the driest desert regions. Both in this region and elsewhere, it is notable that different species have distinct requirements in terms of vegetation cover and height. Accordingly, the Eurasian Skylark abandons cereal fields when these grow taller

In many regions, fire is a natural component of grassland ecology. To nesting larks these fires can spell disaster, but to foraging larks they are a boon. Insects and seeds are relatively easy to find where the vegetation has been destroyed, and thus some birds are attracted to grassland and shrubland fires. The ***Red-winged Lark*** *is one such species, often arriving in numbers only a few hours after blaze has died out. Fire seems to be especially important to Dusky* (Pinarocorys nigricans) *and Rufous-rumped Larks* (P. erythropygia), *which appear to nest almost exclusively in recently burnt areas.*

[*Mirafra hypermetra hypermetra*, Kenya. Photo: Arthur Morris]

Many larks will venture into rocky terrain, or defend territories in boulder-strewn regions, but they rarely forage directly on rocks. Although the ***Thekla Lark*** *is morphologically very similar to the Crested Lark* (Galerida cristata), *it tends to occupy more natural, and less meadow-like, habitats. It generally shuns agricultural landscapes, and prefers barren and rocky slopes, dry steppes, and shrubland on sandy soils. In foraging terms it has no special association with rocks, although it will take advantage of the panoramic view they afford by perching on them, as this photograph attests. This lark, and many others that are not particularly obsessive about displaying in flight, often sing from vantage points of this kind.*

[*Galerida theklae*, Ethiopia. Photo: Roland Seitre]

than 20 cm, Dupont's Lark prefers scrub 40-50 cm tall, the Red Lark (*Calendulauda burra*) selects tall scrub and grass but where the plant cover is only between 5% and 20%, and Rudd's Lark prefers grassland vegetation shorter than 70 cm. With regard to the type and colour of substrate favoured, the best example is perhaps that of the previously mentioned (see Morphological Aspects) lark community of the Kalahari, with six species of "red lark" typical of areas with reddish sandy soils and three "grey larks" in calcrete zones. The way in which substrate hardness is linked with the excavatory habits of certain species, and how this is connected with bill structure, has already been noted (see Morphological Aspects).

Most Europeans associate larks with pastures and croplands. Larks have, indeed, colonized to their advantage such places, not only in Europe but also in many other parts of the world. Pastures and crops, especially if not cultivated intensively, are a perfect equivalent to natural habitats for certain members of the family, which may achieve very high densities there. Moreover, the historical spread of cultivation has allowed larks to colonize new regions, leading to an enormous increase in the geographical spread and population size of a variety of alaudids; a good example is that of the Horned Lark, which underwent an impressive increase in North America at the end of the nineteenth century and at the beginning of the twentieth. Not all larks, however, have benefited in this way. If one considers those genera which contain the most species, *Calendulauda* and *Certhilauda* hardly make use of cultivation, and perhaps one eighth of *Mirafra* species do so regularly, as do about half of the members of *Eremopterix*, *Melanocorypha* and *Calandrella*. It is only in the genera *Alauda* and *Galerida* that a majority of species favour cultivated zones. In general, those larks which exploit agricultural land tend to be more granivorous and to be larger in size than the family average. Within farmland, it is also normal for larks to select fallow areas and crop stubble in preference to the crops themselves, a pattern which may be observed as much among African species, such as the Grey-backed Sparrow-lark, the Pink-billed Lark (*Spizocorys conirostris*) and the Large-billed Lark, as among Eurasian ones, such as the Bimaculated Lark, the White-winged Lark and the Oriental Skylark.

A frequent question examined by students of larks concerns the extent of overlap in habitat use that may exist between species which live together. In general, it may be supposed that differences in morphology and behaviour permit them to occupy different niches, but, on the other hand, the general adaptability of larks and the broad spectra of their diets suggest that such overlaps do exist and, as seems logical, occur to a greater extent between morphologically similar species. The norms of co-existence of the Crested Lark and the Desert Lark have been studied in the Negev Desert, in Israel. Of the two, the former is a larger, heavier bird and it has a longer beak which is better suited to insectivory. It seems clear that the two species are segregated by niche, but that there is also a degree of ecological overlap between them. While both are essentially seed-eaters, the Crested Lark takes a much wider range of seed sizes and it makes wider use of the available habitats, preferring sandy areas to the stony ones which the Desert Lark utilizes habitually, although some overlap occurs between them. Further, the Crested Lark seems to be more opportunistic, a fact which is also reflected in the greater variability of its population size, whereas the Desert Lark is more specialized and better adapted to desert conditions. In connection with this, the Crested Lark tends to carry larger fat stores than does the Desert Lark, perhaps because the latter's dietary specialization enables it to withstand periods of scarcity better than the Crested Lark, which has then to draw on such reserves to a greater extent. It may also be indirectly relevant that the generalist Crested Lark has a wider geographical distribution than that of the specialist Desert Lark.

The two *Calandrella* larks which meet in the Iberian Peninsula, the Greater Short-toed and Lesser Short-toed Larks, provide a good example of co-existence of two morphologically similar species. On a geographical scale, the relative abundance of the two is predictable in terms of such variables as vegetation cover, latitude, longitude and rainfall, whereas, at the level of micro-habitats, noticeable differences between them are evident in such parameters as vegetation height and structure. Nevertheless, the precise mechanisms by which the observed habitat differences between the two species are produced remain a matter for speculation; they may involve interspecific territoriality, colonial behaviour and dietary competition.

At times, dietary differences among alaudids are certainly important (see Food and Feeding) and, in association with differences in migratory habits, they may explain some instances

Most larks live in deserts or semi-deserts. In fact, three-quarters of Afrotropical larks breed in dry habitats. In the same region, only around 10% of larks are associated with a wide range of environments, and a similar number are associated with humid areas and croplands. Thus, in Africa, the epicentre of lark diversity, there is a strong association with deserts, semi-deserts and dusty or sandy grasslands. In Asia, the family is represented by far fewer species, but the pattern is similar. This photograph of a ***Short-tailed Lark*** *not only shows the dry, baked earth of its preferred habitat, but the unique big-billed and short-tailed profile which places it in a monotypic genus.*

[*Pseudalaemon fremantlii delamerei*, Rift Valley, Kenya. Photo: Michael Gore]

of niche segregation. Even so, it is hard to understand the large diversity of lark species which co-exist in such biomes as the South African Karoo, characterized though the region is by great variation in topography, substrate type and colour, climate and vegetation.

Another interesting but little-studied aspect of habitat selection by larks concerns habitat use at different seasons by those species with migratory habits. The movements of some such species involve occupation of different habitats during the breeding and non-breeding seasons. For example, the Bimaculated Lark nests on the Asian steppes but winters in sorghum (*Sorghum*) cultivation in the Sudan, and the Rufous-rumped Lark in Africa nests in open, broadleaf savanna woodland, pastureland and crops but spends the non-breeding period on arid savannas, where it selects recently burnt zones. Both in Europe and in North America, the Horned Lark passes the winter months on beaches and sand dunes along coasts. Nevertheless, these instances are exceptional, and most migratory larks seem to choose, throughout the year, habitats which are similar to those in which they breed.

General Habits

Most lark species are gregarious when on passage and outside the breeding season. Nevertheless, some appear to exhibit year-round territoriality and are seen only singly or in pairs even when not breeding, particularly Afrotropical species, such as Somali Long-billed (*Mirafra somalica*) and Friedmann's Larks (*Mirafra pulpa*), Pink-breasted (*Calendulauda poecilosterna*) and Sabota Larks (*Calendulauda sabota*), the Cape Long-billed Lark and the Large-billed Lark. A further variation is shown by Spike-heeled Larks, which apparently remain in tight-knit groups throughout the year, and have the interesting habit of keeping sentinels posted while other individuals forage.

Flocks of other members of the family vary considerably in size. Over a third of species occur typically in small groups of just a few individuals to a few dozen birds, but some regularly gather in considerably larger numbers. Flocks of hundreds or thousands of individuals occur among species of *Eremopterix*, *Melanocorypha*, *Calandrella*, *Eremophila* and, to a lesser extent, *Alauda*. Within the genus *Melanocorypha*, in which this behaviour is most marked, the Bimaculated Lark forms parties of some 200 individuals and sometimes as many as 3000, and White-winged Lark flocks usually comprise 30-100 birds but may contain 5000 on occasion; similarly, the Black Lark generally occurs in flocks of 500-1000 individuals, although winter aggregations of over 10,000 have been recorded. Even species which do not normally associate in big groups have been seen in large concentrations under adverse conditions, such as snowfalls, probably because snow-free areas in which to find food are then limited in extent. In Switzerland, for example, in an area of approximately 600 hectares in which 1000-2000 Eurasian Skylarks habitually wintered, as many as 5800 of these birds were counted after a

The ***Bar-tailed Lark*** *occurs in sandy deserts and wastelands, often where these are flat and pebbly. In Morocco, and elsewhere in the western Sahara, it prefers stone-clay* regs *(gravel plains with mixed sandy or grassy areas). It is largely sympatric with the closely related Desert Lark* (Ammomanes deserti), *but the latter species tends to occur in a wider variety of habitats, including rockier slopes and dry mountainous regions. Like most larks, the Bar-tailed is a restless creature when foraging; it rarely stands still for long, pausing only briefly between short scuttling bursts of running.*

[*Ammomanes cinctura arenicolor*, Morocco. Photo: Markus Varesvuo]

Larks have adapted rather better than most birds to extremes of aridity, and some of them live in truly inhospitable habitats. They are amongst the only passerines to thrive in the great deserts of the Old World: the Kalahari, Namib, Sahara, Thar and Gobi. The ***Dune Lark*** *is a denizen of the driest parts of the Namib, a harsh environment where few other species can survive. In fact, it almost never occurs in anything but sandy desert, although always in areas with at least some vegetation. Justifiably famed for its physiological adaptation to aridity, it acquires up to 47% of its water requirements through metabolic efficiency. When the water shortage is particularly severe, Dune Larks tend to eat more invertebrates, presumably as these contain a supply of water. They will also drink dew wherever nocturnal fog-banks have passed over the dunes. In the Sahara, the* ***Greater Hoopoe-lark*** *occupies a similar niche, foraging in desolate country and sandy plains, although it does venture into more densely vegetated areas. These two species are typical sand-dwellers: their relatively long bills are useful tools for digging in the soft substrate.*

Larks of high latitudes or altitudes are sometimes forced to forage in the snow. Some populations of the ***Horned Lark*** *breed in the Arctic, where snowfalls are not uncommon, and they survive by digging to search for seeds. During these conditions larks dig hollows or tunnels into the snow, sometimes as much as 30 cm deep, and there they roost. Using these strategies, Horned Larks can survive temporary snowfalls, but they cannot survive very low temperatures or prolonged snow cover. For this reason northern breeding populations are migratory, moving to southerly climes or lower elevations in the non-breeding season. Indeed, they often winter in coastal habitats, such as beaches, saltmarshes and dunes, where the chance of snow cover is minimized.*

[*Eremophila alpestris flava*, Finland. Photo: Markus Varesvuo]

snowfall, with another 9000 individuals in an adjacent area, together comprising some 25 flocks.

Larks generally form loose flocks in which they maintain individual distances of a few metres or a few tens of metres as they walk and feed on the ground or undertake short flights. Much more compact flocks are formed on migration or when predators are present, although these are never so tightly packed as are those of starlings (*Sturnus*), sparrows (*Passer*) and many other gregarious birds. Even so, a huge flock of 4000 Greater Short-toed Larks, recorded on passage in early April in the Arava Desert, on the Israel-Jordan border, appeared very closely knit; as the birds flew en masse from one patch of vegetation to another, they reminded one of the observers of a closely packed flock of small *Calidris* waders.

Concentrations of larks, in all parts of the world, often consist of several species, and often include members of other bird families. Thus, among those alaudids which have been observed to flock in winter or during the dry season, rather more than 40% form multi-species assemblages, a proportion which is likely to be much higher given that many species are still poorly known. The structural similarity between the component members of such gatherings is very variable, as is the number of species involved. *Eremopterix* sparrow-larks, which are morphologically quite similar, tend to associate with each other, for example, the Black-eared (*Eremopterix australis*) with the Grey-backed Sparrow-lark, and the Chestnut-headed with the Chestnut-backed (*Eremopterix leucotis*) and Black-crowned Sparrow-larks. Nevertheless, the participant species are in most cases morphologically dissimilar. Hence, the White-winged Lark, which weighs about 46 g, associates with the Black Lark, at 64 g a notably larger and heavier bird, and the Bar-tailed Lark forms flocks with Dunn's Lark, but also with Temminck's Lark and the Crested and Lesser Short-toed Larks, species from which it differs conspicuously in size and in bill type (see Morphological Aspects). Where birds of other families are involved, associations have been noted with the Corn Bunting (*Miliaria calandra*) and various finch species, such as the Eurasian Goldfinch (*Carduelis carduelis*); also, with Lark-like Buntings (*Emberiza impetuani*) by Stark's Lark and Black-eared and Grey-backed Sparrow-larks. In North America, the Horned Lark forms mixed winter flocks with such species as the American Tree Sparrow (*Spizella arborea*), the Dark-eyed Junco (*Junco hyemalis*), the Lapland Longspur (*Calcarius lapponicus*) and the Snow Bunting (*Plectrophenax nivalis*). The general observation is that such associations form among the most granivorous species, which may be interpreted as a response to the clumped distribution of seeds on the ground, in addition to being a type of anti-predator behaviour.

In contrast to their behaviour outside the breeding season, larks are territorial during the nesting season (see Breeding). This is well demonstrated, for all those species hitherto studied, by the striking songs of many and by the wing-flapping displays of others (see Voice).

As is already evident, larks are open-country birds (see Habitat). Many areas of open terrain take their form as a result of climatic aridity, and it is not surprising, therefore, that many members of this family are typical of arid zones and that some can be found in the world's most inhospitable deserts. It was long thought that these birds lacked physiological adaptations to desert life but, over the last twenty-five years, it has gradually become apparent that this is not so. Larks, in particular, offer interesting opportunites for such physiological investigations, since they allow comparisons, uninfluenced by phylogenetic considerations, of a diversity of species occurring in a range of habitats which differ widely in aridity. J. B. Williams and B. I. Tieleman have been able to demonstrate clearly that desert-dwelling larks expend less energy and lose less water than do those living in non-arid habitats. They compared the Greater Hoopoe-lark and Dunn's Lark, which inhabit the Sahara and the south-west Asian deserts, with the Eurasian Skylark and the Woodlark, which are widely distributed in the middle latitudes of the Palearctic Region. The first two were found to have metabolic rates which averaged 43% lower than those of the last two species; similarly, the desert in-

Some larks habitually perch in trees or tall shrubs. One such species is the ***Pink-breasted Lark*** *of East Africa which usually lands in acacias or thorn bushes when flushed. It lives in open savanna woodland or brushy areas, and is most easily located by its distinctive song, tirelessly repeated by males from a prominent perch. The rather slender bill and long tail of this lark make it seem somewhat pipit-like, and its plain pinkish face is distinctive. It was previously placed in the genus* Mirafra, *but genetic studies suggest that it belongs in the* Calendulauda *clade.*

[*Calendulauda poecilosterna*, Tsavo National Park, Kenya. Photo: Morten Strange]

habitants had a rate of evaporative water loss which was 27% lower than that of the Eurasian Skylark and Woodlark. Such characteristics would be of great adaptive value in desert conditions, where larks have to cope with intense solar radiation, often very high temperatures, low primary productivity and little or no access to drinking water.

The fact that desert-dwelling larks have very low levels of evaporative water loss had previously been demonstrated. For example, the loss rates of Stark's Lark and the Grey-backed Sparrow-lark, two species living in the Namib Desert of south-west Africa, were cited by E. J. Willoughby as being less than half of that which might be predicted for birds of those sizes. It remains unclear by what physiological means such rates are attained. The differences in metabolic rates have been related to changes in the relative sizes of the internal organs, in connection with their own energy demands and with the quantity of food which needs to be processed in different habitats and climates; logically, a lower amount would be needed in warmer and drier places. Physiological changes have been studied by monitoring two captive groups of Greater Hoopoe-larks, one group acclimatized at 15°C and the other kept at 36°C. After three weeks, the birds of the "cool" group had gained body mass, had significantly larger livers, kidneys and intestines, and had metabolic rates averaging 47 kJ per day, in contrast to the 33 kJ per day of the birds in the other group. So far as water-saving mechanisms go, two have been described for other birds of arid habitats: one is hyperthermia, allowing the body temperature to rise to approach that of the environment, thus reducing the need for evaporative cooling; and the other involves counter-current heat-exchange mechanisms in the nasal spaces. Neither of these would be very effective in the case of larks, as has been shown by laboratory studies. It is now thought that differences among alaudid species may involve differences in cutaneous water loss, related to variation in epidermal lipid composition and changes in cutaneous vascularization.

An additional method of conserving water is to reabsorb as much as possible from the urine and the faeces. Indeed, it has been demonstrated that the normal water content of the excreta of Stark's Lark and the Grey-backed Sparrow-lark is about 75% but that, when the birds are deprived of water, this can fall to little more than 50% and sometimes to as low as 25%. Be that as it may, it is evident that larks seem to need very little water. In fact, there are five species in the arid south-west of Africa which have never been seen to drink at all, and another, the aforementioned Grey-backed Sparrow-lark, which, although it visits water-holes in the wild, has proved in captivity to be capable of surviving indefinitely without water, living solely on a diet of millet seeds. Larks meet much of their water demands by metabolic oxidation of their food; the Dune Lark (*Calendulauda erythrochlamys*), also a Namib species, derives up to 47% of its requirements in this way. Much also is obtained from particular foodstuffs, notably insects and the green parts of plants, which may be sought with special dedication. The Dune Lark, for example, spends about a third of its foraging time in searching for invertebrates, which it must certainly seek in places distinct from those in which it obtains seeds. It seems, moreover, that invertebrates become more important in the diet at times of drought. In Pakistan in winter, when insects are not readily available, the Crested Lark turns to cultivated shoots of rape (*Brassica napus*) and chickpea (*Cicer arietinum*) plants during periods of severe drought, these being the only circumstances in which it is known to damage crops. In the African Kalahari, it is only the most granivorous lark species that visit drinking spots. Dew is another possible source of water in some places, and it is known to be used from time to time by the Dune Lark, which is otherwise famed for its physiological adaptations to aridity. It is also interesting to note that, under arid conditions, some alaudids are capable of drinking brackish water, as has been observed for the Black-crowned Sparrow-lark, White-winged, Black, Crested and Raso Larks, and Eurasian Skylarks.

Together with these sorts of adaptations, there is no doubt that appropriate behaviour is essential for desert larks if they are to avoid overheating and excessive water loss. Unlike mammals such as rodents, which emerge from their burrows only at night, larks are diurnal, but they concentrate their activities during the cooler hours of the day, around dawn and dusk. This is especially so with their foraging efforts and, in particular, their song flights, which demand high levels of energy expenditure (see Voice). Many species begin singing before dawn and again after sunset. In the Namib Desert, Gray's Lark, for example, performs most of its song flights in the period from two hours

No lark can properly be called a forest bird. The ***Woodlark*** *is one of the very few members of the family that comes close to qualifying for this category, but it is more a bird of clearings, heathlands and forest edges, preferring a mix of grassy glades and bare patches amongst shrubs and trees. Unlike most other larks, it often perches on high branches. In the traditional taxonomic sequence, the Woodlark occupies the monotypic genus* Lullula, *and this format is retained here. However, the basis for separating* Lullula *from* Alauda *seems flimsy on morphological grounds, and the best solution might involve a merger of these two genera.*

[*Lullula arborea arborea*, Silchester Common, Hampshire, England. Photo: Andy & Gill Swash]

before dawn until sunrise, with a second song period beginning 30 minutes after sunset. Nocturnal singing also occurs among temperate-zone species such as the Woodlark, which often sings on warm, moonlit nights.

With regard to foraging, a study of the Greater Hoopoe-lark in Arabia has shown that the birds forage for an average total of 5·5 hours daily, as opposed to 6·3 hours spent in resting. They foraged intensively for the first two hours after dawn, approximately from 06:00 to 08:00 hours, and during the last hour before sundown, from 17:00 to 18:00 hours. From 08:00 to 10:00 and from 16:00 to 17:00 hours, they foraged by moving from one patch of shade to another, with short intervening periods of rest or preening. The middle hours of the day were spent almost exclusively in resting. The experimental provision of supplementary food supplies demonstrated, however, that it is food shortage that obliges these larks to extend their foraging into the hotter hours of the day; those which had access to extra food not only reduced their foraging period, by between 13% and 29%, but also began and ended their rest periods at temperatures a couple of degrees lower than usual. It is curious that there is an apparent lack of time-budget studies for alaudids living in habitats other than deserts, but with these species, too, vocal activity and foraging occur mostly in the early morning and in the evening; the middle hours of the day, except in winter, are only partly spent in feeding and are otherwise devoted mainly to resting and plumage maintenance.

Inactivity at midday and the utilization of shade are widely employed strategies among larks, including those species in habitats which are not particularly arid, but there are other methods of combating the effects of heat. In 1957, J. A. Valverde noted that Thekla Larks in Western Sahara perch on bushes much more often than they do in Spain, and that they also choose high positions, well away from the overheated ground, in which they are exposed to the breeze, thus benefiting from a more favourable micro-climate. Similar behaviour has subsequently been recorded elsewhere, involving, for example, the Horned Lark in the Mojave Desert of California, USA, and both Stark's Lark and Gray's Lark in the Namib Desert of Africa. In Saudi Arabia, the Greater Hoopoe-lark cools itself by lying on mats of the tiliaceous plant *Corchorus depressus*. Similarly, in Kuwait, a further three alaudids, Dunn's Lark, the Bar-tailed Lark and Temminck's Lark, make use of *Citrullus colocynthis*, a prostrate plant of the family Cucurbitaceae having long roots which reach the water table and which can therefore cool itself by stomatal transpiration; in the Sahara, the temperature of its leaves has been found not to exceed 41°C when the air temperature has reached 54°C and the ground temperature is 70°C. Some other larks may find refuge from the midday heat in the burrows of other animals. For example, the Spike-heeled Lark in the Kalahari enters those of a ground squirrel, *Xerus inauris*, and in the Arabian Desert up to four species use the burrows of the large lizard *Uromastyx aegyptius*. Among these, the Greater Hoopoe-lark, the biggest species, seems to do so more than the others. The birds descend to a depth of 20-30 cm and remain there for about five-and-a-half hours each day during June and July, when the external air temperature can reach 45°C. Given that the temperature of the burrows does not exceed 41°C at midday, it has been calculated that this strategy may reduce the larks' evaporative water loss by over 80%.

Larks appear to roost at night on the ground. The roosting behaviour of the Crested Lark, in particular, has been well studied, but similar observations have been made on the Thekla Lark, the Greater Short-toed and Lesser Short-toed Larks and the Eurasian Skylark. Each bird uses its bill or legs to excavate a shallow depression of about half its own body size, and spends the night therein, as evidenced by the accumulation of droppings. The location of such roosting places is very variable; sometimes they are on totally bare ground and on other occasions they may be sited in the shelter of a small shrub. The distance between the roosting depressions is also variable, tending to be relatively great during the breeding season, but comparatively small when the birds are flocking in winter or in dry seasons. In the latter circumstances, inter-roost distances of 2-5 m have been noted for the Crested Lark and of only 10-15 cm for the Black Lark. The same depression may be used for several days, up to six consecutively in the case of a captive Crested Lark, but it is more usual for them to be abandoned after one day, especially if there is any disturbance or poor weather. Young Crested Larks construct and utilize roosting hollows from the age of about twelve days. Larks occasionally excavate sleeping hollows in snow, a habit which is well known for the Black Lark, and which has

Although larks are usually pair-living and territorial in the breeding season, they tend to be gregarious at other times of year. When the ***Horned Lark*** *abandons its montane or northerly breeding grounds each winter, it gathers in small flocks. These tend to be rather loosely packed, with a few metres separating foraging birds. In the photograph, however, these Horned Larks are visiting a water-hole in an arid landscape, and here they are packing together more tightly. For some lark species, flocks containing many hundreds of individuals have been recorded, and in the Black Lark* (Melanocorypha yeltoniensis), *Bimaculated Lark* (Melanocorypha bimaculata), *and some* Eremopterix *larks, these loose gatherings can run into tens of thousands; in the non-breeding season, equally impressive flocks of Greater Short-toed Larks* (Calandrella brachydactyla) *can be seen in North Africa and the Middle East. These dense congregations seem to be constantly on the move, especially in spring and autumn, propelled by low bounding flight across wide stretches of desert, cultivation and open water.*

[*Eremophila alpestris*, Washington, USA. Photo: Dave Maslowski/ Maslowski Productions]

also been reported for the Horned Lark and, occasionally, the Eurasian Skylark. The hollows made in snow by the Black Lark are 10-13 cm wide and 5-10 cm deep, usually reaching the ground surface. Those constructed by Eurasian Skylarks have been observed to be somewhat deeper, 20-30 cm, and to have a small terminal chamber.

Dust-bathing is a characteristic aspect of alaudid behaviour. Other passerines, such as sparrows and buntings, also dust-bathe fairly regularly, but the habit seems to be universal among larks, both those of arid and semi-arid zones and those of more northerly distribution. J. D. Delius has described the dusting behaviour of the Eurasian Skylark in some detail. For this species, the process follows a series of seven stages: first, the bird pecks at the ground; it then fluffs up the plumage, spreads the tail and drags the wings on the ground; after this, it uses its claws to excavate the surface, pushing the sand or soil outwards; the wings are then beaten against the ground; in the fifth stage, the lark scatters the soil with the bill; it then adopts a posture as if sun-bathing, remaining immobile for a short time; in the seventh, final stage it repeats the entire sequence. This behaviour is connected with the need to keep the plumage clean and also, perhaps, with the control of parasites. Interestingly, some lark species indulge in a similar sequence of movements and postures, but with the sand or soil replaced by snow, effectively snow-bathing.

Perhaps somewhat surprisingly, there appear to be hardly any reports of larks bathing in water, and such as there are involve very few species. This could be interpreted as one further adaptation of the family to arid environments.

Voice

The complexity and quality of lark song are as noteworthy as the birds' plumages are sober, a combination that is not uncommon among passerines. The possession of dull plumage, as necessitated by the general adaptation of the Alaudidae to steppe habitats and, especially, to nesting on the ground (see Breeding), may have led to a greater investment in song as a means of advertising individual quality among territorial males. This process has met with the problem that the habitats typically exploited by larks have few or no elevated songposts, such as trees or rocks, that would permit songs to be transmitted farther and would reduce the likelihood of singers being surprised by terrestrial predators. The solution is that larks, as a rule, sing in flight, notwithstanding the high energy costs involved. All of the Palearctic species, without exception, have song flights, and the same applies to the great majority of the African and Asian larks, although they may be lacking in some species of *Spizocorys* and *Mirafra*. In any event, there is no doubt that song flights constitute one of the behavioural traits which best characterize the family.

An excellent example of singing in flight is provided by the Eurasian Skylark, the vocal performance of which is surely also the best known and the most studied, given that its originator is a very common bird in the European countryside. The performing male rises silently into the wind and ascends to a height of between 10 m and 20 m before breaking into song. He continues to climb little by little, singing as he does so, following a spiral track and with the tail spread, to attain an altitude of about 100 m, and sometimes considerably higher; a study in southern Sweden, using an optical range-finder, found that the birds reach a height of 120 m on average, with a range of 31-210 m. At the peak of his lofty ascent the male lark remains, singing throughout, with wings flapping at 10-12 beats per second, until the moment of descent, which usually involves a parachute-like, gently spiralling glide on still, open wings. This descent may continue down to the ground, with the bird singing all the way, or may be cut short abruptly, ending with a dive on closed wings. The total duration of the display is very variable, but in general it is surprisingly long in comparison with the aerial displays of other birds. Different studies give average durations of between two and five minutes, but these timings depend in large measure on whether or not the tentative and frequently curtailed song bouts of the ascent are included. The duration is also influenced by the prevailing stage of the reproductive cycle, since the songs are considerably longer during the territory-occupation phase than during incubation and, especially, when the young are being fed. Song flights exceptionally last 10-15 minutes or even longer; in England, 57 minutes was recorded on one occasion and 68 minutes on another, such virtuoso exploits being hard to imagine.

So far as is known, there are no data available on the energy costs of song flights, but no doubt these are very considerable and the birds' behaviour seems designed to reduce them as much

Dust-bathing is a common feature of lark behaviour. It has been reported for most species in the family, and it seems likely that no group of passerines spends more time dust-bathing than larks, with the possible exception of sparrows (Passer). *Before indulging in their characteristic dusting and sunning behaviour, larks choose a warm, open, sunlit spot, as demonstrated by this* ***Bimaculated Lark***. *Here, they fluff up their plumage, spread their wings against the ground, and sometimes flutter dust onto their feathers. This behaviour probably functions in maintaining plumage quality, and reducing parasite load.*

[*Melanocorypha bimaculata*, Sohar, Oman. Photo: Hanne & Jens Eriksen]

*Many larks live in hot, dry places where physiological and behavioural thermoregulation is essential. To avoid overheating, this **Spike-heeled Lark** opens its bill, the normal avian version of panting. This species often spends the middle of the day resting in the shade, sometimes in the underground burrows of terrestrial mammals. In general, larks adapted to arid environments show low levels of energy expenditure and evaporative water loss, characteristics which allow them to cope with a shortage of drinking water and an excess of solar radiation.*

[*Chersomanes albofasciata*, Kalahari Gemsbok National Park, South Africa. Photo: Andy & Gill Swash]

as possible. The aforementioned Swedish study, undertaken by A. Hedenström, determined that the skylarks flew at an optimal speed of some 6 m per second and that they were obliged to circle to maintain height only when wind speeds were lower than that figure; at higher wind speeds, they could maintain station with minimal exertion by facing into the wind. Song-flight duration has been found to have a positive correlation with the length of time spent on the ground immediately afterwards, the birds apparently recuperating after their exertions. It has also been shown that an experimental reduction in wing area leads to shorter song flights.

All in all, it seems evident that the most significant feature of the aerial display of the Eurasian Skylark is its total duration. The staying power of males appears to be the principal indicator used by them in order to advertise their reproductive quality and competitive status to females and rival males, respectively. From an evolutionary standpoint, the length of song flights may be regarded as subject to sexual selection, being a characteristic which has been elaborated upon and exaggerated, in the same manner in which other birds have developed size and plumage distinctions and other forms of behaviour. The question arises, therefore, of the extent to which song-flight endurance can be taken as an "honest" signal, one which is not susceptible to cheating by those males which are in reality inferior to the image which they present of themselves. The evolution of such a feature as a lengthy song flight seems to be accompanied by others which serve to reduce its energy costs, in this case the development of a larger wingspan and a greater wing-and-tail surface area, a distinction which is already evident between males and females. Selection for such cost-reducing traits, the employment of which is more economical than is that of elaborate sexual displays, would seem to facilitate cheating, whereby poor-quality males could pass for what they are not. It appears, however, that this does not apply in this particular instance, as A. P. Møller has shown that, although many individuals with poor displays do have relatively large wingspans, suggesting that they benefit from energy-saving features, it is also the case that the individuals with the longest song flights have the largest wingspans. In other words, the possession of cost-reduction traits such as large wings does not allow poor-quality individuals to offset the costs of protracted song flights, the key indicator of fitness, to the extent seen in genuine high-quality birds. The signal remains honest, therefore, in that the evolution of energy-saving measures is followed by that of a higher quality of display, which itself serves to augment the costs involved, and these higher costs can be met only by the fitter individuals.

It is the essential honesty of this signal that perhaps permits it to be employed effectively in a very different context, that of anti-predator behaviour. A Scottish study of the reactions of Eurasian Skylarks to attacks by Merlins (*Falco columbarius*), carried out by W. Cresswell, showed that the larks may use their songs as a pursuit-deterrent signal. The observer found that the falcons pursued for longer periods those larks which did not sing when fleeing, and they also chased poor singers more than they did the more accomplished ones. In this instance, song is serving as a pointer to body fitness and gives the Merlins a reliable indication of the relative likelihood that an attack will succeed.

So far, nothing has been said about the quality of the song of the Eurasian Skylark, which has been much exalted by poets (see Relationship with Man). It is, indeed, an unending and inspiring melodious stream of clear and well-modulated trills and warbles. Above all, the listener's attention is drawn to the way in which the phrases appear to follow one another so smoothly, and seemingly without pause. If the song is recorded and analysed from sonagrams, however, its continuity is found to be more apparent than real; there are, in fact, distinct phrases separated by brief pauses, perhaps corresponding respectively to the expiratory and inspiratory phases of respiration. The phrase/pause pattern is independent of the wingbeat pattern, which is much faster. Phrase lengths are variable, but there are usually fewer than four per second. The pauses are so short, lasting only 0·03-0·1 seconds, as to be undetectable by the human ear. Sonagrams reveal that within each phrase there are pulsatory bursts, at times with the elements tightly packed but at other times less so, which suggests that respiratory oscillation of the airflow is superimposed on cycles of contraction of the syringeal musculature. Another curious revelation from the sonagrams is that the range of vocalizations is relatively limited, even though these are combined in an enormous variety of different ways, with little repetition. It is very probable that sexual selection has influenced song continuity, song structure and other aspects of these vocalizations, as has been demonstrated for various other bird species. In this

connection, it is interesting to note that female Eurasian Skylarks also sing, both from the ground and in flight, although their songs tend to be quieter, more monotonous and more fragmented than are those of the males.

In common with many other avian families, the Alaudidae often incorporate imitations of other birds, and sometimes other types of sound, into their songs. There is the intriguing instance of a Crested Lark in Germany which was observed to imitate the whistles by which a shepherd controlled his sheepdog; so good was its mimicry that the dog was found to respond appropriately to recordings of the bird. At least as remarkable is the case of a Rufous-naped Lark in Kenya which, while on the ground, uttered exclusively its imitation of the Abyssinian Nightjar (*Caprimulgus poliocephalus*), instead of its own song; this resulted in days of perplexity among the ornithologists who found the bird, and who were baffled at having apparently located a nightjar which sang by day. The Eurasian Skylark mimics the voices of some birds, among them waders such as the *Tringa* species and *Charadrius* plovers, and those of the introduced Australian population have been known to imitate psittaciforms such as the Galah (*Eolophus roseicapillus*) and the Blue-winged Parrot (*Neophema chrysostoma*), but this lark is not especially celebrated as a mimic. Mimicry is better developed in larks of the genera *Melanocorypha* and *Calandrella*. The song of the Calandra Lark, for example, includes continuous, frequent and convincing imitations of a whole range of species; in central Spain, these may include the Common Quail (*Coturnix coturnix*), the Greater Short-toed Lark, the Crested Lark, the Barn Swallow (*Hirundo rustica*), the Spotless Starling (*Sturnus unicolor*), the Eurasian Goldfinch, the Eurasian Linnet (*Carduelis cannabina*) and many others, indeed practically all of the species that share the Calandra Lark's habitat. Some of the African *Mirafra* species, including the Red-winged Lark and the Melodious Lark (*Mirafra cheniana*), seem to be as good or even better at mimicry. For the former, imitations of 20 species were identified in fifteen minutes of recordings from Tsavo National Park, in Kenya, and a single 12-second phrase comprised imitations of five species intermixed with the lark's own whistles. The Melodious Lark, a southern African species, has been credited with imitating at least 57 species, drawn from some twenty different families.

The existence of song flights has paved the way for other kinds of display which, while not strictly vocal, may come to be as effective as song in the contexts of sexual and territorial advertisement. In such activities many larks employ them to a greater or lesser extent. The aerobatics which embellish the celebrated fluting song of the male Greater Hoopoe-lark provide a particularly good example (see Breeding).

Finally, flight provides the opportunity to produce sounds other than vocalizations, as it does with some other groups of birds. With the Alaudidae, these non-vocal sounds are due to the striking together of the wings on the downstroke. Such sounds have been noted for a range of species from different genera, including *Melanocorypha*, *Chersophilus* and *Heteromirafra*, but it is the larks of the genus *Mirafra* in which they are most widespread and in which they are used to the most spectacular effect. Wing-clapping is generally combined with vocalizations, but in three African species, the two clapper larks and the Flappet Lark (*Mirafra rufocinnamomea*), wing sounds predominate to such an extent that it was long thought that the Flappet Lark produced no song at all, although some individuals are now known to do so. As this last species cruises more than 100 m above its woodland territory, its wingflaps are audible over hundreds of metres, and are at least as loud as the vocalizations of other larks. The wing noises are delivered in bursts, the duration and pattern of which vary from place to place and comprise a sort of local "dialect" which remains constant for long periods at a given site, and which is equivalent to the song dialects of other birds. The wingflaps are produced at a frequency of 24 per second, twice as many as in normal flight, indicating that the displaying males incur a very high energy cost, perhaps 16 times greater than their basal metabolic rates. This kind of display is likely, therefore, to be a more than honest indicator of the relative quality of individual males. Of the half-dozen or so wing-clapping larks, the Cape Clapper Lark (*Mirafra apiata*) is the only other one in which the flap rate accelerates greatly during the display. Maximum wing-clap rate varies less than do other display characteristics, with very little variation among the fastest-clapping males, suggesting that there is direct selection for fast clapping.

Aside from songs and mechanical sounds, alaudids do, of course, have a number of vocalizations which they use in differ-

During aggressive interactions or territorial disputes larks tend to hold their wings away from their bodies. They also fluff up their plumage and those that have crests, like this ***Eurasian Skylark****, raise them. This all goes to make them seem as large as possible to their rivals. It is rare for confrontations to develop beyond this stage, but longer-billed larks sometimes grasp each other's bills and tussle on the ground. More often than not, one contestant rapidly concedes and the victor gives chase. In many species, the wing-out display is similar to the postures seen during initial stages of courtship, wherein the wings are drooped and quivered.*

[*Alauda arvensis cantarella*, near Ankara, Turkey. Photo: Hanne & Jens Eriksen]

In sharp contrast to their muted plumage, most larks have conspicuous, distinctive and often beautiful songs. This ***Dupont's Lark*** *is singing from a low perch; the species also performs a song flight, which is of varying duration. Although it sings chiefly around dawn and dusk, it can sing almost throughout the night in spectacular fashion. In the daytime, singing males rise to great heights, sometimes 100-150 m above the ground, where they can deliver prolonged bouts of song. The song itself is a short, powerful and melancholy phrase that carries well across the favoured habitat of this species, the shrub-steppes of Spain and North Africa.*

[*Chersophilus duponti duponti*, Navarre, Spain. Photo: José Luis Gómez de Francisco]

ent behavioural contexts, as, for instance, when flocking. These calls, however, do not appear to differ in any substantial or significant way from the corresponding calls of many other passerines. The repertoire of the Eurasian Skylark, presented in a well-known study by Delius, serves as a typical example. In addition to its songs, this species has at least eight other types of vocalization. A rapidly repeated "tschrr tschrr" is given by the male in advertising display, a quiet, hoarse "gjj gjj" is uttered in threat, a rapidly repeated "schrr" and a plaintive, drawn-out "juu" are contact calls, and a repeated soft "tju tju" is a feeding call. The flight call is a liquid, rippling "tschirit", sometimes transliterated as "chirrup", the latter being a common human spelling of the calls of many bird species. The other vocalizations of the Eurasian Skylark are "tlütütü tlütütü", given by a disturbed individual during brood-rearing, and "iuiu iuiu", which is the food-call of the young.

Food and Feeding

Despite the existence of noteworthy interspecific differences in bill morphology (see Morphological Aspects), the diet of adult larks in almost all cases comprises seeds and invertebrates, although the relative importance of these differs among species. Green vegetation is also taken frequently, as are, to a lesser extent, small bulbs and fruits. Thus, of the 70 or so species for which dietary details are reasonably well known, about 70% consume a mixture of seeds and invertebrates, some 20% additionally eat green vegetation, and only about 10% are specialist insectivores or seed-eaters, although even these last may occasionally consume other material. In nearly all cases, the nestlings are fed exclusively on invertebrates, the few exceptions being found among the most granivorous species, such as Stark's Lark, which feed even tiny young on the seeds of herbaceous plants.

A great diversity of invertebrate groups is represented in the alaudid diet. In addition, certain species, such as the Greater Hoopoe-lark, have been seen to capture small reptiles on occasion. The invertebrate prey normally consists of arthropods, but small or medium-sized snails and other invertebrates are also taken. The contribution made to the diet by different kinds of invertebrate seems to reflect the local abundance of each, in keeping with the generalist nature of most alaudids. Thus, Afrotropical larks rely heavily on termites (Isoptera) and also, to a lesser extent, on ants (Hymenoptera), despite the chemical defences of the latter, although other arthropods, including beetles (Coleoptera), grasshoppers (Acrididae) and spiders (Araneae), are also well represented in their diets. Orthopterans and beetles predominate in the diet of north African species, although ants are also taken by the Greater Hoopoe-lark and the Desert Lark.

The songs of the genus Eremopterix *tend to be simple affairs. They are usually repetitive series of twittering or buzzy notes. They are sometimes given in high song flights, but are more commonly produced from the ground or low perches, as shown here by an* ***Ashy-crowned Sparrow-lark****. Apart from advertising signals, larks tend to have a fairly wide variety of quieter secondary vocalizations used in flight, when flocking or during agonistic encounters. Flocks of* Eremopterix *larks, for example, give a chorus of finch-like chipping or twittering notes when flushed from the ground.*

[*Eremopterix griseus*, India. Photo: Gertrud & Helmut Denzau]

*The song of the **Rufous-naped Lark** is a short and simple three- or four-note phrase monotonously repeated every 2-20 seconds. After about 20 repetitions of one particular phrase, the bird switches to another call type. On this occasion the male is singing atop a bush, but he sometimes performs a short song flight. Not infrequently, especially when excited, he also rattles his wings immediately prior to singing. Mechanical noises such as this are common in larks, with some species basing most (or all) of their advertising signal on wing-clapping rather than vocalizations. Mimicry is rare in the Rufous-naped Lark, but the norm in some of its relatives. In common with all oscines, larks learn their songs when they are young. According to one report, however, they sometimes listen to inappropriate tutors: at a site in Kenya, a Rufous-naped Lark had learned the song of the Abyssinian Nightjar* (Caprimulgus poliocephalus)*, and it repeated this phrase incessantly.*

[*Mirafra africana athi*, Masai Mara National Park, Kenya. Photo: Ferrero-Labat/ Auscape]

*Of the various larks that perform prolonged song flights, the **Eurasian Skylark** is the most famous. A prominent feature of the European spring, its aerial displays have long inspired poets and musicians. For minutes on end they pour out a medley of notes, trills and warbles, sometimes from so high in the air that they are hardly visible. Much as this "flood of harmony" is uplifting to humans, it has a practical function: showing off. The available evidence suggests that females can judge the quality of males by the duration of their song flights, and can thus use these flights to guide their mating decisions.*

[*Alauda arvensis*, Dogubayazit, Turkey. Photo: Hanne & Jens Eriksen]

For four lark species studied in the Iberian Peninsula, namely the Crested and Thekla Larks, the Eurasian Skylark and the Woodlark, beetles comprise the majority of arthropod prey, although grasshoppers, ants, caterpillars and spiders are also included. The seeds taken by larks range in size from cereal grains down to the very tiny ones, and the range of plant species exploited is very broad. Most are grass seeds (Poaceae), but sometimes the seeds of shrubs, weeds or cultivated plants predominate. In common with many other birds, all those larks which are at least partially granivorous also ingest small stones in order to facilitate the breaking-down and digestion of the seeds.

There are sometimes sexual differences in the diets of larks. As already noted, male larks are larger than females, the differences in body sizes and bill lengths being more marked in insectivorous species than in the seed-eaters (see Morphological Aspects). Hence, intersexual dietary differences may logically be expected to exist. In the case of the Spike-heeled Lark, which has been studied in the Namib Desert, the males feed mainly upon tenebrionid beetles and the females on ants and harvester termites. Males of the Raso Lark, which are more given to digging for food, consume more bulbs than do the females, which have a more insectivorous diet.

Another important factor of variation in alaudid diets is the season. Not only are the chicks of nearly all species totally insectivorous but, at least among the Holarctic members of the family, the nesting adults, too, take mainly insects. Data on Spanish Thekla Larks illustrate the progressive dietary change during the course of the breeding season: in April, arthropods comprise 70% of the stomach contents in terms of volume, 20% being seeds and the remainder stones; in May, seeds predominate in some stomachs and invertebrates in others; in June, arthropods make up only 8% of the stomach contents, with seeds representing 60% and green matter 13%. Such seasonal differences seem to be related to the energy content of the different components and to the need of individuals for water. R. E. Green has shown that Eurasian Skylarks in England, after the harvest has taken place, prefer cereal grains to green matter, although they continued to eat other food even when the former were abundant. Green matter, which is comparatively low in energy, dominated in the winter diet, when cereal grains were scarce, although the larks appeared to select fields mostly according to the density and size of the available cereal grains. It seems, therefore, that green vegetation usually comprises a secondary element in the diet, although for desert species, and during periods of drought, it may be important as a source of water.

Given that larks in general have a mixed and varied diet of seeds and insects, it is not surprising that many of them are often seen to explore the dung of herbivores. This material contains numerous undigested seeds, of a considerable variety of sizes, and harbours the adults and larvae of coprophagous beetles, which can be extraordinarily abundant in places where livestock is not treated against digestive parasites or where large wild ungulates occur. Such behaviour has been reported for at least seven genera, with species including the Rufous-naped Lark, Karoo Lark, Dusky Lark, Gray's Lark, Desert Lark, Red-capped Lark (*Calandrella cinerea*) and Crested Lark. The investigation of dung may be habitual among species with a bill morphology suited wholly or partly to insectivory.

The foraging behaviour of larks takes a variety of forms and is related to the morphology of the species. The most granivorous alaudids, with the shortest bill and legs, move slowly while searching the ground meticulously for seeds. The insectivorous ones, with long bill and legs, often run from place to place or, where the substrates are soft enough, dig for insects. It is amazing to watch the Greater Hoopoe-lark as it extracts beetle larvae from the sandy accumulations, known as *nebkhas*, which form in the lee of small desert shrubs; the bird digs furiously and determinedly to a depth of up to 5 cm, leading one to wonder how it is that the lark detects the prey in the first place. Bulb-eaters, such as the Short-tailed Lark (*Pseudalaemon fremantlii*) and the Large-billed Lark, also dig for their food, and the Raso Lark excavates down to 6 cm in order to unearth the bulbs of *Cyperus bulbosus*. Species of snowy regions will also dig through the snow to reach seeds, as does the Black Lark, which excavates tunnels up to 15-20 cm deep, sometimes with side branches.

There are some other styles of foraging behaviour which appear quite specialized. The Karoo Lark, which often digs in sand, seeks termites in the excavations made by the aardvark (*Orycteropus afer*), a mammal with which it associates; the Eastern Clapper Lark occasionally does the same. Dupont's Lark hunts tarantula spiders (*Lycosa*) in their burrows, which are often quite deep and narrow, by inserting its long beak and often also its neck, assuming a leg-up and tail-up posture which recalls the upending behaviour of dabbling ducks (*Anas*). Various alaudids, such as the Raso Lark and Temminck's Lark, use the bill to turn over pebbles in search of insects hidden beneath; the latter spe-

The diet of all larks consists almost entirely of seeds and insects, in varying proportions, depending on species and season. Here we see a ***Rufous-naped Lark*** *carrying a praying mantis, and a* ***Greater Short-toed Lark*** *holding a small worm in its bill. As these images attest, mantids, annelids, and a range of other insects and invertebrates, are eaten by larks, but in almost all cases they are captured more intensively during the chick-rearing phase than at any other time in the life-cycle. In other words, when adults are not breeding, they probably rarely forage on such large living prey. In some cases, even bigger prey is tackled. The Greater Hoopoe-lark* (Alaemon alaudipes) *has been observed capturing and consuming small vertebrates, such as reptiles, on occasion.*

Larks typically detect food items by sight, and pick them from the surface using their bills. Many species, however, dig to reach invertebrates or bulbs, and in this case the food must be located by touch. The ***Sabota Lark*** *is mainly granivorous, but it eats invertebrates when it can, as shown here. Like most larks, it knocks large insects against the ground to break them up into smaller pieces. Interestingly, bill morphology varies between races of this species, and races with bigger bills tend to spend more time digging for food; the bird seen here is one of the larger-billed, western forms.*

cies is known to turn over stones as heavy as its own body. Particularly remarkable is the use of stone "anvils" on which to smash snails before ingesting their soft contents, an activity which has been much studied in the Song Thrush (*Turdus philomelos*) and which has also been described for a number of lark species, including the Crested Lark, the Thekla Lark and the Greater Hoopoe-lark. The feeding style of the Thekla Lark is very similar to that of the Song Thrush. The lark grasps the snail by the shell rim and then smashes it against a small rock in a series of rhythmic sideways blows until the shell breaks, usually along its upperside, upon which the bird seizes the snail's foot in its bill and shakes it brusquely to complete its extraction. Individual Thekla Larks select particular rocks to be used as anvils, as evidenced by the piles of accumulated shell fragments, but they also choose particular snail species according to size and to the hardness of their shells. Hence, the birds in the study area selected only one out of three available snail species, and they took only the smallest individuals of this one. Such selectivity has not been noted among Song Thrushes, and it may be due to the fact that Thekla Larks are considerably smaller birds. The much larger Greater Hoopoe-lark smashes snails by dropping them from heights of up to 25 m, although it also uses anvils when dropped snails fail to break.

Larks are by no means the only seed-eaters that occur in deserts. The gerbils (Gerbillinae), small mammals inhabiting north Africa and the Middle East, are predominantly granivorous and may be supposed, therefore, to be in serious competition with alaudids. Their interactions have been studied in Israel, in the Negev Desert, where the Crested Lark co-habits with Allenby's gerbil (*Gerbillus allenbyi*) and the greater Egyptian gerbil (*G. pyramidum*). A series of experimental trials was carried out in a variety of micro-habitats and substrates, employing baits consisting of seeds mixed with sand, and with seed densities recorded before and after foraging had taken place. This revealed that, when seed densities were very low, the gerbils were more efficient at extracting seeds than were the larks. In theory, Crested Larks could compensate for their relative inefficiency in two ways. On the one hand, and given their mixed diet, they could switch to other prey types when seeds were too scarce to be worth harvesting. Alternatively, they could employ their much greater mobility to locate patches with higher seed densities or to visit habitats, such as rocky hillsides, which gerbils seldom or never exploit.

Breeding

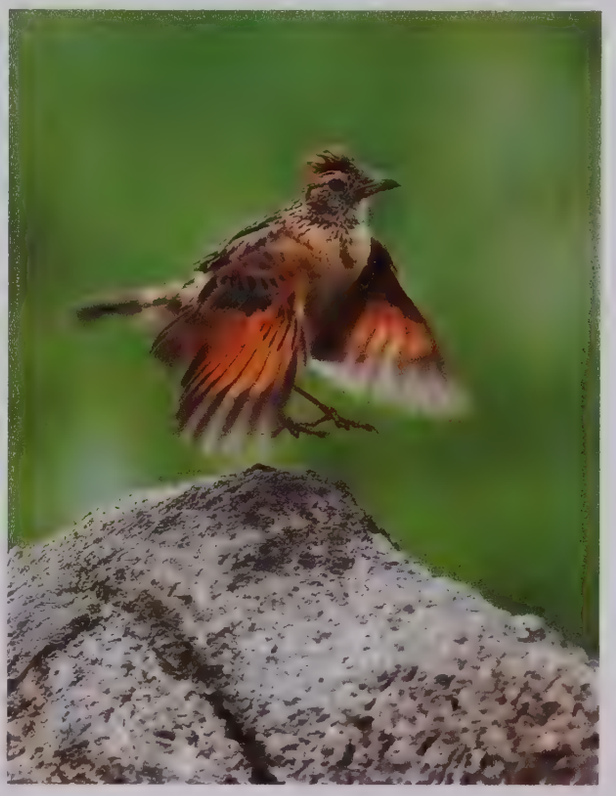
The breeding habits of the Alaudidae, although subject to notable exceptions, may be summarized by stating that: the members of this family are monogamous and territorial; they breed as isolated pairs or in loose colonies; their nests are constructed on the ground, by the females; clutch size varies considerably; the eggs are incubated usually by the females alone; the chicks grow very rapidly and are fed by both sexes; losses of eggs and nestlings are high; and the young depend on their parents for a relatively long period after fledging.

For most members of the family, seeds are a staple. Larks tend to eat a variety of grain sizes, from cereals down to tiny seeds. Most are grass seeds, but seeds of large bushes, small shrubs, and cultivated plants, are also commonly taken. Most seeds are eaten from the ground, this being because larks do not usually perch on the stem of grasses, unlike many granivorous emberizids. The only time they strip seeds from the parent plant is when the stem is very short, allowing the seed-head to be reached from the ground, as shown by this ***Black-crowned Sparrow-lark****.*

[*Eremopterix nigriceps melanauchen*,
Oman.
Photo: Markus Varesvuo]

Many larks dig for their food, but those that dig most avidly are species of sandy deserts, such as the ***Dune Lark****. Because of their habit of sifting through sand for prey, larks adapted to soft substrates tend to have longer bills than those living on harder ground. The longest bill of all belongs to the Greater Hoopoe-lark* (Alaemon alaudipes)*, a species that often digs several centimetres into sand to reach food items. It regularly searches for seeds and insects hidden in banks of sand that build up on the windward side of desert shrubs. Some other dry-country species with shorter bills, such as the Raso Lark* (Alauda razae) *and Temminck's Lark* (Eremophila bilopha)*, habitually flip over stones when foraging. The latter species has been known to turn stones heavier than its own body weight. Perhaps the most remarkable digging feats are performed by larks in deep snow: they sometimes dig burrows 15-20 cm deep to reach the ground, and then tunnel under the snow in search of food.*

[*Calendulauda erythrochlamys*, Sossus Vlei, Namibia. Photos: Josep del Hoyo/ Lynx Edicions]



In dry conditions many larks visit sources of water to drink, probably on a daily basis. This generalization is most accurately applied to species of semi-deserts and grasslands, such as the ***Calandra Lark****. It also tends to be true of species with a high proportion of grain in their diet. Conversely, species that eat insects and green vegetation rarely drink, and larks of true deserts are well adapted to the arid environment. Through a variety of behavioural and physiological strategies, including a highly efficient metabolism, many of them appear to spend their entire lives without ever needing to drink water.*

[*Melanocorypha calandra calandra*, Belchite, Spain. Photo: Jordi Bas]

Whereas many larks are gregarious outside the breeding season, all are territorial when nesting, as indicated by their singing behaviour and, in some cases, their wing-flapping displays (see Voice). Nevertheless, the spatial distribution of territories indicates that many gather to breed in defined zones, forming what may be considered loose colonies. Such a pattern has typically been recorded for mainly granivorous species, including Black-eared, Chestnut-backed, Black-crowned and Grey-backed Sparrow-larks, as well as for Dupont's Lark, the Calandra Lark, Greater and Lesser Short-toed Larks, the Horned Lark and Sclater's Lark (*Spizocorys sclateri*). Others, such as all members of *Certhilauda* and most of *Calendulauda*, in addition to the Eurasian Skylark, the Crested Lark and the Thekla Lark, which are typically more insectivorous, have their territories evenly spread and well spaced. The existence in some species of intraspecific gregariousness in the breeding season poses certain questions. The underlying reason for this behaviour has been explained by two factors, which are not mutually exclusive: the existence of sharp differences in habitat quality; and defence against predation. Although the open terrain which larks inhabit may appear homogeneous, there are in fact often major differences in vegetation structure between areas which may be only tens or hundreds of metres apart. In addition, the rainfall patterns in arid and semi-arid regions can be extremely irregular, and it is the rains that determine food availability. Larks will tend to concentrate in the most "valuable" habitat patches, those in which they are likely to attain the highest reproductive success. As regards anti-predator defence, the benefit of forming loose colonies comes from the shared vigilance and alarm displays which make it less likely that nests or adults will be attacked by predators, thus again increasing overall breeding success. In general, lark nests suffer heavily from predation, which may include the loss of the incubating adults.

Factors which determine the onset of breeding by desert-dwelling larks differ from those applicable to larks of temperate climates. The rains are the trigger to nesting by the former, whereas northern species are more influenced by temperature. Relatively little is known on this subject with regard to Asian and Mediterranean species.

Larks of desert habitats nest during the rainy seasons, when primary production is much higher and insects are at their most abundant. A southern African species, Sclater's Lark, provides a good example. Its preferred food is the seeds of eight-day grass (*Enneapogon desvauxii*), so called because it germinates, grows, flowers and sets seed in just eight days after the onset of the rains, and the reproductive cycle of this lark species is geared to the development of this plant. Nevertheless, reproductive strategies differ from one species to another. In the Namib Desert, Willoughby found that the Spike-heeled Lark, which is sedentary and predominantly insectivorous, has no seasonal pattern to

In common with most members of the family, the male ***Rufous-naped Lark*** *spends much of the breeding season defending its territory or advertising for mates by singing and displaying. Of the various displays used by larks, a small hop into the air from a prominent perch is unique to certain members of the genus* Mirafra. *This hop, captured here, is accompanied by an audible whirr as the bird flutters its wings. It often serves as a precursor to songs or displays, and it is sometimes given in series during longer song-bouts.*

[*Mirafra africana africana*, Ngoye, Kwa-Zulu Natal, South Africa. Photo: Andy & Gill Swash]

Unlike many desert species with patterns of breeding tied to fluctuations in rainfall, ***Stark's Lark*** *has a fixed cycle of gonadal development so that it always breeds in the late summer or autumn. It achieves this constancy by dispensing with a fixed breeding range. Instead, it is nomadic and nests wherever sufficient rain has fallen. As in most larks, the female builds a cup-shaped nest in a suitable depression, sometimes in the open, but more often sheltered by vegetation. In this case, a small clump of grass provides a modicum of camouflage and shade. The genus* Spizocorys *contains six African species, all with dull plumage and finch-like bills.*

[*Spizocorys starki*, near Brandvlei, Bushmanland, Northern Cape, South Africa. Photo: Peter Steyn/Photo Access]

its gonadal development and in its moult, but instead reproduces opportunistically in response to local rainfall. A somewhat different strategy is exhibited by Stark's Lark and the Grey-backed Sparrow-lark, which are nomadic and largely seed-eaters. These two species have an endogenous cycle of gonadal development and moult which is coupled to the rains, so that they tend to nest mainly in late summer and in autumn. Their nomadism makes this possible, since they are able to move rapidly to areas which have received rain. Similar observations have been made in the Kalahari Desert. Nevertheless, the same species may or may not display gonadal cycles, and the Grey-backed Sparrow-lark does not show them in the Kalahari.

The onset of breeding in desert habitats is linked to the quantity of rainfall, and the birds are able to respond very rapidly to appropriate amounts of precipitation. The resident insectivorous larks of the Namib require a minimum of 20 mm of rain for nesting to be triggered, and they are able to begin such activities just seven days after heavy rain. The nomadic seed-eating species require up to 40 mm and they begin nesting two weeks after rain, although this may be delayed for a couple of months, depending on how the vegetation develops. Reproduction is influenced not only by rain but also by temperature, the latter also affecting productivity in desert ecosystems; high temperatures encourage rapid plant growth but the vegetation may be short-lived, whereas low temperatures will reduce plant growth rates and can delay egg-laying. Temperature, through its effects on the endurance of desert plants, can also determine the length of time over which breeding activity lasts; high temperatures may curtail the season and may lead to a high rate of nest abandonment.

Larks, being territorial, have traditionally been regarded as strictly monogamous. This does, indeed, seem to be the case for the Eurasian Skylark, which shows a high level of mate-fidelity from one season to the next. Other species, however, often change their mates annually, the Woodlark being one such example. Other arrangements exist, and co-operative breeding has been recorded in both Spike-heeled and Gray's Larks. There are reports of breeding Crested Larks consisting of trios of adults, and in Spain there are three observations of Lesser Short-toed Lark nests at which two males fed the brood; the possibility that the extra birds were helpers cannot be discarded. The fact that many larks nest semi-colonially, and that constant and obvious conflict between neighbouring males is evident, suggests that extra-pair paternity may occur extensively. Indeed, unpublished Spanish data on the results of DNA testing revealed that the sole chick in one Lesser Short-toed Lark nest was not the offspring of the male nest-owner, although it was the female's, and again, in a brood of three chicks of the Greater Short-toed Lark, the female was the mother of all but the male of the pair was the father of only two of them.

The well-known song flights of alaudids have already been discussed (see Voice). In many cases, the singing male hangs in the air or moves in circles or arcs, or simply drifts around in the air current. In others, however, such territorial advertisement is accompanied by more spectacular aerobatic displays, perhaps the best example of which is that of the Greater Hoopoe-lark. The male of this desert-dwelling species leaps skywards from the top of a shrub or a mound, rises some metres while emitting wonderful fluting sounds and, having attained the high point of its trajectory, spins around and plummets groundwards, bill first, with the wings tightly pressed to the body until the very instant of landing. This flight provides the opportunity, through wing-flapping and the spreading of the tail, for the bird to show off the striking plumage markings, namely the broad black and white bands on the wings, which recall those of its name-giver the Hoopoe (*Upupa epops*), and the white-bordered black tail. Many other lark species reveal display markings during their song flights; these are typically the otherwise hidden black-and-white wing and tail patterns, but in some cases those markings present elsewhere on the body, as with the sides of the neck of *Melanocorypha* larks, the head and neck of *Eremophila* and the underparts of *Eremopterix*.

Aggressive interactions between rival males are frequently observed. These confrontations take two distinct forms. In one, the contestants face up to each other on the ground, each holding the wings spread, the head and chest feathers erect and the body plumage fluffed up so as to make the individual appear larger than it really is. With some species, such as Dupont's Lark, they seize each other's bill and rotate the head violently in an attempt to twist the rival's neck. The second type of contest, which may also be interspecific, involves chasing an intruder or opponent in flight, as occurs among many other

passerines inhabiting open areas. Both types of behaviour are often observed during a single conflict.

The process of pair-bonding is often quite similar in nature to the male's antagonistic behaviour. Aerial chases are most frequent in the early stages of the reproductive cycle, at least in the case of the well-studied Greater Short-toed Lark, whereas interactions on the ground tend to occur once pairs have already formed. These terrestrial displays involve postures with the body held horizontal, the crest, breast and body feathers erected, the tail open and raised and the wings drooped, and movements including wing-quivering and the rapid dancing or running by the male in front of the female, as well as, sometimes, songs and calls. Copulation by Greater Short-toed Larks takes place on the ground, normally after a pursuit-flight.

Nest-construction is generally by the female alone, but the task is shared equally by both sexes of some species, including the Chestnut-backed Sparrow-lark, the Rufous-tailed and Desert Larks, the Malabar Lark (*Galerida malabarica*) and Sykes's Lark (*Galerida deva*). In other cases, the male may simply accompany the female as she gathers nesting material, although occasionally he may bring some contributions for the female to incorporate. The nest is nearly always on the ground, normally in the shelter of a small shrub, tuft of grass or rock. Many species of semi-arid regions, however, site their nests completely in the open and, in contrast, the Cape Clapper Lark and the Collared Lark sometimes build within a clump of grass. Only the Greater Hoopoe-lark builds its nests habitually off the ground in small bushes, although it, too, sometimes nests directly on the ground.

Nest-building begins with the excavation of a small depression in the soil. This is not unlike a roosting hollow (see General Habits) in appearance, but is distinguishable in that it does not contain accumulated faeces and it is somewhat deeper. The female builds a basal platform of small stones, pellets of soil or twigs, before assembling the wall and lining from carefully positioned grass stems. Quite a few Afrotropical larks construct a canopy over the nest, which they begin as soon as the hollow has been dug and which they later extend to include the rim of the nest, before completing the nest cup within. Domed nests of this kind are, in fact, characteristic of certain genera, so much so that they were once considered of relevance for purposes of taxonomy. Almost all *Mirafra* species build them, the sole exception being the Somali Long-billed Lark, the few located nests of which were undomed. Nest canopies are also typical of the genera *Heteromirafra* and *Calendulauda*, although, among the latter, the Pink-breasted Lark seems to be an exception. In *Pinarocorys* they have been noted for the Dusky Lark but not for the Rufous-rumped Lark, and in *Certhilauda* the nests of the Short-clawed Lark (*Certhilauda chuana*) are undomed and those of the Cape Long-billed Lark only occasionally have canopies. The nests of other lark genera are open, although individual birds may build canopies on rare occasions, as has been reported for the Woodlark.

Another intriguing feature of alaudid nests, although not exclusive to this family, is the extension of the nest platform to form an exterior "rampart" or "apron", which can be quite striking when, as with some species, it is built from pebbles. This external adornment may encircle the nest or, as is often the case, form a pathway at the entrance. Some species make the rampart from twigs, but the Black Lark uses the dung of livestock. Nests of the Black-eared Sparrow-lark and Stark's Lark are particularly showy, since the rampart comprises a rim of sand bound with spiders' webs, materials which are also used to a lesser extent by the Pink-billed Lark and the Spike-heeled Lark. The functions attributed to nest ramparts are diverse, and range from a possible protective role against windblown sand to an anti-predator role in camouflaging the site. Nests with ramparts are more widespread among species of arid or semi-arid zones: across the rainfall gradient which runs northwards from north Africa across Europe, all the typically desert species make pebble ramparts whereas, among the typically Mediterranean larks, they are seen at only a minority of the nests of the Thekla, Lesser Short-toed, Greater Short-toed and Dupont's Larks, all of which use sticks. Among the northern species, only the Horned Lark decorates the nest at times with small stones, a habit which is practised more rarely still by the Eurasian Skylark and the Woodlark. All of this suggests that ramparts may help to shelter nests from the highest temperatures reached on desert floors, which may exceed the tolerance of developing embryos or cause overheating of the brood. A comparison has been made of intact Desert Lark nests with others at which the ramparts had been removed experimentally,

Several Afrotropical larks build a modified nest with a domed roof. The nest of the ***Red Lark****, for example, is overarched by an interwoven mesh of fine grass stems. This type of canopy is usually constructed after the hollow has been made, but before the lining of the cup has been added. It conceals the nest contents and thus presumably minimizes predation. Interestingly, the entrance of domed nests is often orientated away from the sun's zenith, and the dome is sometimes absent in well-shaded sites. These facts, coupled with a lack of nest orientation in winter, suggest that shade is an important consideration for larks breeding in hot climates.*

In larks, as in most passerines, the importance of nest camouflage is paramount. Despite extreme differences in breeding habitat, an incubating ***Woodlark*** *is just as inconspicuous on an English heath as an incubating* ***Desert Lark*** *in the wilds of Jordan. The plumage of the former is dark and variegated, while that of the latter is pale and uniform. These features help larks and their nests blend into the background, and increase the likelihood that they will escape the attention of predators. The Desert Lark is among several members of the family noted to build "ramparts" around their nests. This feature, usually a raised rim of pebbles or sand bound with cobwebs, is just visible here. It is thought that ramparts are useful in three ways: they improve camouflage; defend nests against windblown sand and debris; and help to keep them cool. This Desert Lark has tucked her nest against a rock which might cast some shade early or late in the day. Any shade is valuable in the desert, as nest temperatures can exceed 50°C at midday, and adult larks are obliged to shield their eggs from the sun's glare simply to keep them cool.*

[Above: *Lullula arborea arborea*, Sussex, England. Photo: Dennis Green/ Oxford Scientific Films.

Below: *Ammomanes deserti isabellina*, Jordan. Photo: David Hosking/ FLPA]

In most larks, incubation begins with the laying of the last egg and ends 11-13 days later, or a little longer for the larger species. In general, incubation is the responsibility of females alone, although both adults share the task in at least one species of Mirafra *and most* Eremopterix. *This female* ***Thick-billed Lark*** *has positioned her nest beside a small shrub, which provides protection against the strength of the sun for part of the day. Her bold facial markings help to break up her outline and reduce the chances of detection by predators. In addition to a unique head-pattern, this North African lark has much the largest bill of any alaudid, and occupies a monotypic genus as a result.*

[*Ramphocoris clotbey*, Morocco.
Photo: Michel Gunther/Bios]

and the former were, indeed, found to be cooler than those without ramparts during the hottest hours of the day, perhaps because the stones heat up more slowly than the ground. The suggestion, made by Y. Orr, that the pebbles act as storage heaters which serve to incubate the eggs during the cool of the morning, allowing the incubating female to leave the nest and to forage for long periods at that time, is not supported by temperature measurements of the stones themselves. In any event, nest temperatures in the desert can approach 50°C during the hottest hours, which obliges the parents to cover eggs or young in order to shield them from the worst of the heat. Some species, such as the Grey-backed Sparrow-lark, when faced with substrates too hard for them to dig into, will build a large mound of stones, on which they can then form a cup.

Females differ in the quality of their nest structures. The differences have been found to be age-related in the case of the Dune Lark, in which undomed nests are built by females in their first year. Ramparts have been found to be more frequent in the early nests, holding first clutches, of the Thekla Lark, the Lesser Short-toed Lark, the Greater Short-toed Lark and the Iberian populations of the Eurasian Skylark, but are rarely present in replacement nests. It has been suggested that, in the Alaudidae, nest decorations may serve as an indicator of mate fitness. Such a role has been identified in the case of the Black Wheatear (*Oenanthe leucura*), the nests of which also incorporate a stone rampart; with this species, there is apparently a positive relationship between the number of pebbles used and the quality of the male that brings them, the nests with more pebbles enjoying higher reproductive success. Among alaudids, it is the female that builds the nest, but the explanation may be the same: the nest embellishments may indicate to the male the quality of his mate, ideally serving to reinforce the pair-bond and to maintain the male's fidelity. This is important, as the males have a key role in feeding and caring for the brood. A high-quality nest may also indicate the female's capacity to lay replacement clutches, an important consideration in view of the fact that so many lark nests are lost to predators.

The achieving of a favourable nest temperature is also a determinant of nest-siting. Most larks choose a site in the shadow of a shrub or rock, so that, especially in desert environments, the nests are sheltered from solar radiation and the worst of the heat. With the Sabota Lark, domed nests are less frequent among those constructed in the shade. In the case of Afrotropical species south of the equator, the nest entrance faces south, south-east or east, away from the sun when at its strongest. That of Mediterranean larks generally faces north or north-east, but in this region the timing of nesting is also influential; first clutches, laid early in the season when temperatures are more benign, are often in nests which are orientated at random or which have a slight tendency to face south, but second and replacement clutches, laid when temperatures are much higher, are almost invariably in nests which open northwards. In contrast, in cold environments, the Horned Lark sites its nests in such a way as to maximize their exposure to solar radiation. Finally, with regard to nest location, it has been demonstrated that the Lesser Short-toed Lark and the Thekla Lark prefer sites which offer good visibility in the vicinity of the nest, which would appear to be an anti-predator arrangement designed to maximize the likelihood of escaping from or distracting an approaching predator.

Clutch size is highly variable in the family, ranging from a single egg, as is always laid by Sclater's Lark, to up to 6 or 8 eggs in the Calandra and Black Larks. Clutch size appears to be relatively constant within certain genera. In *Mirafra*, *Heteromirafra* and *Calendulauda* it is 2-4 eggs, with an average of between 2·2 and 3·5, the exception being the Dune Lark, which nearly always lays two eggs; in *Pinarocorys* the normal clutch size is also two, whereas in *Ammomanopsis*, *Chersomanes*, *Certhilauda* and *Spizocorys* it is normally two or three. Clutch size is much more variable in the remaining genera. It seems to be clearly related to environmental aridity, even within species, being lower in drier zones. Thus, the Desert Lark lays 1-4 eggs in desert areas, but farther north the clutch is of 3-5 eggs; similarly, the Chestnut-backed Sparrow-lark normally lays two eggs, but in drier Senegambia it lays only one. In Montana, USA, a desert-living race of the Horned Lark has been found to have larger clutches in wetter years than in drier ones, and in some species such as the Grey-backed Sparrow-lark clutch size can increase in relation to rainfall even over just a few days. Alaudids do not seem to comply with "Lack's rule", which states that the clutch sizes of many birds tend to increase with higher latitude. In the

Rates of predation at lark nests are usually very high, often 80-90%, and breeding success consequently tends to be low. Heavy losses are inflicted by reptiles, such as snakes and lizards; birds, such as crows; and terrestrial mammals, for example, foxes, mongooses, weasels and hedgehogs. All of these eat eggs and nestlings, or even adult birds if given half a chance. In response to such pressures, this female ***Thekla Lark*** *has hidden her nest carefully in low vegetation and will not flush until almost stepped on, relying on her camouflage for protection. As might be expected, her eggs are also cryptically patterned with spots and blotches.*

[*Galerida theklae theklae*, Tudela, Navarre, Spain. Photo: José Antonio Martínez]

case of the Eurasian Skylark, at least, the mean clutch sizes of populations in Algeria/Tunisia, Spain and France are all very similar, at 3·76, 3·73 and 3·75 eggs, respectively; these figures are greater than the 3·35 in Switzerland and 3·64 in Britain, and not much smaller than those for Germany, the Netherlands and Estonia, where the respective means are 3·87, 3·92 and 3·97 eggs. In England, it has been noted that clutch sizes of this species are larger in the middle of the laying period than they are at either the beginning or the end of the season.

The number of clutches laid in a season is not known for most members of the family. Among those studied, however, the Chestnut-backed Sparrow-lark, the Desert Lark, the Bimaculated, Calandra and White-winged Larks, the Greater Short-toed and Lesser Short-toed Larks, the Horned Lark and the Woodlark are all normally or often double-brooded, while some species, such as the Greater Hoopoe-lark, are usually single-brooded. Others, including the Crested and Thekla Larks, may raise between two and four broods in a single breeding season, as also does the Eurasian Skylark, which can, on rare occasions, rear as many as five. The Dune Lark, too, although normally regarded as being double-brooded, may raise between one and four, and a similar pattern appears in the Short-clawed Lark. The proportion of females laying different numbers of clutches remains largely unknown, but in the case of the Calandra Lark only 30% of females lay second clutches.

Alaudid eggs are very cryptically patterned, as would be expected for ground-nesting birds. The clutch is laid at the rate of one egg per day. Nest parasitism has been observed among larks, albeit affecting fewer than 1% of nests. Such behaviour has been recorded both within species, as illustrated by the Crested Lark and the Thekla Lark, and between species. Interspecific nest parasitism can involve congeners, as with the Lesser Short-toed Lark parasitizing the Greater Short-toed Lark, or members of different genera, as exemplified by the Lesser Short-toed Lark parasitizing Temminck's Lark, or the Crested Lark laying in the nest of the Sand Lark (*Calandrella raytal*); moreover, it has been noted that parasite young tend to fledge sooner than do those of the legitimate brood. Nevertheless, in contrast to the situation that occurs among ducks, it does not appear that any individual larks specialize in egg-dumping behaviour. It seems most probable that, instead, nest parasitism results from opportunistic laying by females which have lost their own nests to predators during the egg-laying stage, and which find themselves obliged to dispose of eggs which they were about to lay. This circumstance is supported by the fact that abandoned eggs are rather frequently found in small depressions in the soil, these perhaps belonging to females which have lost their own nests and have been unable to find another in which to lay.

For most of the species sufficiently studied, incubation is undertaken by the female alone, although there are exceptions. There is a general lack of relevant information for the genus *Mirafra*, but in the case of the Australasian Bushlark, at least, incubation involves both sexes, as commonly occurs among *Eremopterix* sparrow-larks, and perhaps also occurs with some species of *Galerida*, such as the Malabar Lark and Sykes's Lark, and with one of *Alauda*, the Oriental Skylark. In some species, including the Pink-billed Lark and the Black-crowned Sparrow-lark, incubation begins with the first egg, but in the great majority it starts only when the clutch is complete or, as with the Thekla Lark, when the penultimate egg has been laid. The incubation period is short, lasting 11-13 days in most species, though up to 14 days in the Greater Hoopoe-lark and 15-16 days in the Black Lark. Some sparrow-larks breeding opportunistically in arid areas have extremely short incubation, averaging 9·6-10·2 days, with some records of merely eight days; these are among the shortest incubation periods of any bird.

Nestlings of all lark species are cared for by both parents, which feed them and remove faecal sacs, although it is normally the female that broods the chicks or shades them from the sun when they are between one and four days old. The chicks have a sparse covering of down on the dorsal surface, which is effective in camouflaging them. They grow very rapidly, at or near the fastest rate that is physiologically possible. In nearly all instances, the young are capable of leaving the nest once they are seven or eight days old, although, if undisturbed, they sometimes remain there for up to 12-14 days. Once fledged, the youngsters hide in the vicinity of the nest and continue to be fed by the parents. The post-fledging period of care is relatively long: in all members of the family for which this aspect has been studied, the young take nearly a month to become independent of their parents.

In the first few days after hatching, it is usually the female that broods the chicks at night or shades them from the sun during the day. The chicks themselves have a sparse covering of down on their upperparts, presumably to insulate them from the cold, and to provide camouflage. Despite being several days old, these ***Eurasian Skylark*** *nestlings still wear conspicuous tufts of down on their crowns. As this photograph implies, the skylark is a species of grassy meadows. Given the shortage of natural meadows in Western Europe, many nests are situated in the next best thing: crop fields. Of course, the breeding season is thus truncated by the harvest, and many nests are destroyed at harvest time. In this way, agricultural intensification, in conjunction with shifts in sowing and cropping strategies, underlies the massive decline in skylark populations across Europe. Recent research has shown that breeding success is greatly increased when farmers leave small strips of natural grass and hedgerow between their crops. Skylarks prefer to breed in these strips, and thus far fewer nests are destroyed. This practical approach to lark conservation is promoted by agencies in Britain, even leading to the launch of "skylark-friendly" bread.*

[*Alauda arvensis arvensis*, Rednal airfield, Shropshire, England. Photo: John Hawkins/ FLPA]

*The **Thekla Lark** is relatively common in parts of southern Europe. Here, intensive studies have shed some light on its breeding cycle. The incubation period begins with either the last or the penultimate egg (there being 3-5 eggs in total) and continues for 12 days, after which the chicks hatch. The brood is then raised by both parents, which usually manage to produce two, or even three, broods per season. The species is socially monogamous, in common with most larks. Individuals usually retain their partners for successive clutches, but occasional extra-pair copulation has been recorded.*

[*Galerida theklae theklae*, La Rioja, Spain. Photo: José Luis Gómez de Francisco]

Mortality in the nest tends to be high, and is a factor of great importance in lark population dynamics. Among species living in the least transformed habitats, be they Afrotropical, north African or Mediterranean, as many as 80-90% of nests are lost; those larks inhabiting man-modified environments, such as the Calandra Lark, the Crested Lark and the Eurasian Skylark, normally lose 30-50%. The rates of nest loss also seem to be related to aridity, being greater in drier habitats; the pattern is unclear, however, given that, in Iberia, both Mediterranean and Eurosiberian lark species suffer very high losses. Most nest losses are due to predators, predominantly generalists such as foxes (Canidae) and crows (Corvidae), but mongooses (Herpestidae), weasels (*Mustela*), hedgehogs (Erinaceidae), snakes and large lizards, among others, are also implicated. In arid areas of southern Africa, nest flooding can be a significant cause of failure, for example in the Grey-backed Sparrow-lark and Stark's Lark. Partial losses, involving starvation of some members of a brood, are uncommon.

Inevitably, larks are relatively well adapted to cope with such high losses of eggs and broods. On the one hand, they are capable of laying replacement clutches quite rapidly; a lost nest may be replaced after barely 2-4 days, with re-laying beginning 4-6 days after the initial predation event. In addition, the rapid growth rate of the chicks allows females to begin a second clutch before the first brood fledges, leaving the males to care for the young, a duty in which nest helpers have been found to play a role in the cases of the Short-clawed and Spike-heeled Larks, at least. It has also been suggested that clutch size is adjusted to the likelihood of loss, the high levels of predation favouring smaller clutches; these represent a smaller investment, are exposed to predation for a shorter time during the egg-laying phase, and can be replaced more quickly if necessary. Such a strategy seems to be exemplified by Sclater's Lark, the single-egg clutch of which may be a response to the attentions of mongooses and African polecats (*Ictonyx*). Another anti-predator adaptation shown by this desert species is the siting of the nest in the middle of bare expanses of quartz gravel, despite the heat which it must endure there, instead of in places with shrubs or grasses which, although providing shade and camouflage, are more frequented by predators. Finally, alaudids, in common with many other birds, resort to distraction displays in an attempt to lure predators away from nests. In such situations, they make themselves conspicuous and draw attention to themselves with loud calls, sometimes also performing mock attacks on any intruders. As may be expected, the frequency and intensity of such behaviour increase with the age of the eggs or chicks and, hence, with the parental investment which it represents.

Perhaps also as a consequence of the high mortality at the nest stage, the few available data on the population dynamics of larks suggest that these are long-lived birds, relatively more so than are other passerines of similar sizes. Longevity of up to ten years has been recorded for the Eurasian Skylark in England, where five-year-old birds are frequently encountered, with a mean annual mortality of some 33%. In the USA, a Horned Lark which had been ringed as an adult was recovered seven years later, by which time it must have been at least eight years old. The Dune Lark in the Namib Desert may reach six years of age, and a breeding Lesser Short-toed Lark in Spain was at least five years old.

Sex ratios in the Alaudidae appear to exhibit some interesting features, notwithstanding the fact that they have been little studied. Among Crested Larks in Turkmenistan, for instance, males greatly outnumber females and, moreover, the proportion increases in favour of males during the course of the annual cycle: the ratio of males to females at fledging is 1·9, rising to 2·7 in spring and up to 4·3 in winter. This implies greater mortality among females, perhaps because the males of this species, as those of most larks, do not take part in incubation, when females are especially vulnerable to predation. A similarly skewed sex ratio has been found for the Black Lark; in one study, over two-thirds of fledglings were males. The numerical inequality between the sexes may have added to the selective pressures leading to the evolution of the dramatic aerial displays of male larks (see also Voice).

Movements

Larks exhibit a great diversity of movements, including regular and partial migration, vagrancy and nomadism. Many species, however, are entirely sedentary. Among others, it is often the case that some populations of a single species undertake one kind of movement, while others either perform another type or are sedentary. There are links between the types of movement undertaken and the degree of sociability of a given species, as well as

the nature of its diet. The nomadic larks of the southern African deserts are gregarious seed-eaters, whereas the sedentary species in the same region tend to be solitary and more insectivorous. The same seems to apply among the larks of north Africa. According to statements in the literature, of the ten species which habitually spend the winter months within the north African desert, the two having a bill shape indicative of a predominantly insectivorous diet, Dupont's Lark and the Greater Hoopoe-lark, are sedentary. In contrast, of the three species which have a seed-eater's bill, the Lesser Short-toed and Thick-billed Larks are more or less nomadic and the Calandra Lark undertakes movements of unknown extent.

Most larks are, in fact, residents. This is especially true of the Afrotropical species, 90% of which can be so described. Nevertheless, in general, only around 20% of the world's lark species may be considered to be strictly sedentary. Among the remainder, nomadic or wandering larks are more numerous in Africa and alaudids with migratory populations are more frequent in Eurasia. This situation is obviously related to patterns of food availability, which are more predictable on a seasonal basis on the steppes and in other Eurasian habitats than they are in the arid and semi-arid regions of Africa.

There are few members of the family in which all or most of the populations are migratory. Among the Eurasian species, this applies solely to the Bimaculated, White-winged, Greater Short-toed and Hume's Larks, and even here the southern populations of the last two species may be only partially migratory. The Bimaculated, Greater Short-toed and Hume's Larks travel great distances. The first of these three breeds from Asia Minor and the Near East eastwards to Central Asia, after which it migrates mainly to Pakistan and north-western India, although some of its populations undertake shorter journeys to winter in the Middle East and others reach north-eastern Africa. The Greater Short-toed Lark breeds from the Maghreb and Iberia eastwards to Iran and Central Asia and winters mostly in Africa, south of the Sahel and the Red Sea, between latitudes 17° and 14° N. Finally, Hume's Lark breeds in Asia, from eastern Iran across to central China, and spends the winter months primarily in the north and centre of the Indian Subcontinent, although some of its populations apparently perform only short-distance altitudinal movements. Among Afrotropical alaudids, only the Dusky Lark is known to be entirely migratory, breeding in Central Africa during the dry season, from July to October, and then moving mainly south and east; in South Africa, it is recorded mainly between December and April. The movements of many Afrotropical species, however, are still poorly known.

The tendency for different populations of a species to exhibit different kinds of movement is most marked in widely distributed northern species. This is well illustrated by the Horned Lark, the northernmost populations of which, in both Eurasia and North America, are completely migratory, whereas those farther south are resident or do no more than undertake altitudinal movements or short-distance dispersal. Even among species with a more southerly distribution, such as the Crested, Lesser Short-toed and Calandra Larks, it is noticeable that the north African populations are sedentary or, at best, wander, whereas those breeding farther north, in Russia, are total or partial migrants which travel long distances.

For some alaudids, the types of migratory behaviour have been noted to differ according to sex and age-class. In central Europe, the passage of female Eurasian Skylarks occurs about a week earlier than that of the males, and it appears that, on average, the females travel farther. In contrast, the males return to the breeding grounds in spring ahead of the females, as also occurs among Horned Larks in North America. Young Black Larks disperse farther in winter than do adults.

Migratory movements undertaken by alaudids are often on a broad front, but concentrations can occur at mountain passes or along coastlines. Eurasian Skylarks move largely by day, especially during the first few hours after sunrise, although their calls have been heard as the birds make landfall from sea crossings at night. Horned Larks seem to be entirely diurnal migrants, and this idea is supported by the fact that there are no records of this species flying into such obstacles as masts and lighthouses during the night. They travel in flocks, which often stop to feed.

Relationship with Man

Few passerines are more familiar to people than are larks. This is somewhat surprising in view of the fact that the family Alaudidae contains only a moderate number of species, of sober plumage,

As far as is known, nestlings of all lark species are attended by both their parents, with males and females investing roughly the same amount of effort provisioning their offspring. Sharing of parental duties in members of the genus Eremopterix, *such as the* ***Black-eared Sparrow-lark****, is especially egalitarian as males also carry out about half of the incubation. This species is endemic to the Kalahari and Karoo regions of southern Africa, where it is nomadic. As in several other lark species with erratic breeding ranges, pairs tend to nest in clumped aggregations, sometimes only 20 m apart, wherever suitable conditions prevail.*

[*Eremopterix australis*, near Brandvlei, Bushmanland, Northern Cape, South Africa. Photo: Peter Steyn/ Photo Access]

and inhabiting chiefly parts of Africa and Asia that are sparsely populated by humans. The explanation for this must be sought among a handful of species which, probably since Neolithic times, have accompanied the development of human agriculture. Such species, which include the Eurasian Skylark, the Calandra Lark and the Crested Lark, are closely tied to cultivation, as is suggested by the scientific name of the Eurasian Skylark; *Alauda arvensis* means "lark of the fields". It is in cultivated fields, especially in crops of wheat and other cereals, that they attain high densities, and here they lay claim to the auditory landscape with their incessant songs, delivered on the wing. Their impact on western culture is well known and of long standing, as testified by their ancient Greek names, such as *corytalos* and *calandros*, or Latin ones, such as *galerita* and *alauda*. This last name was adopted by Linnaeus for the single genus in which he placed all the lark species known to him, and it is now the type genus of the family Alaudidae.

Pliny the Elder, the renowned Roman scholar and natural historian, relates that the sonorous name "*alauda*" came to the Romans from the Gauls. Apparently, one of the legions which took part in the Gallic wars came to be so named, according to some, because its members wore their insignia on the peak of the helmet, recalling the crest of a lark, although others claimed that the name was due to the soldiers' constant ebullience, especially at dawn, when they sang their war songs. From *alauda* are derived, among other names, the French *alouette*, the Italian *allodola*, the Catalan *alosa* and the Spanish *aloya* and *alondra*. In contrast, a Germanic root is responsible for the German *lerche*, the Swedish *lärka*, the Icelandic *lævirki*, the Dutch *leeuwerik*, the Galician-Portuguese *laverca*, the Scottish *laverock* and, evidently, the English "lark".

Early written observations of larks date back at least to Aristotle, who commented on some interesting aspects of the lives of these birds, namely that they dust-bathe like chickens and that cuckoos (*Cuculus*) lay in their nests, although, curiously, he does not seem to remark upon their song flights. In order to find an account which first does such behaviour justice, it is necessary to advance to the thirteenth century, to the writings of Albertus Magnus: "*avis est a laude vocata, eo quod musica sereno et calido congaudet tempore... mas ejus musicus est valde et multae modulationis, aestaten primo inter aves praenuntians et diem in aurora promens laude cantus sui*". This passage may be translated as follows: The bird's name derives from *laude*, meaning praise, for its music gives great pleasure in the seasons of peace and warmth... The highly modulated music announces, first among birds, the summer and signals the first light of day with the praising of its song.

From this time onwards, references to the voices of larks become the most frequent allusions to birdsong throughout western literature, with only the nightingale (*Luscinia*) to rival them. References to both of these birds are often made at the same time, the nightingale being cast as king of the night and the lark as "herald of the morn", to quote William Shakespeare. There is the well-known scene in the play *Romeo and Juliet* in which, after the two leading characters' first night of love, the song of a bird startles Romeo, who takes it to be the first lark of the day, whereas Juliet, trying to delay her lover's departure, reassures him that it is but a tardy nightingale. Allusions to larks are legion in English poetry, from Chaucer's "bisy lark, messager of daye" to Shelley's "blithe spirit", and through the works of Tennyson, Gray, Hood, Walton and so many others, all of them marvelling upon this little dun bird which loses itself upon the heights to "pour upon the world a flood of harmony", as wrote William Wordsworth. It is rather odd that, in the Spanish literature, it is the *calandria*, the Calandra Lark, that is initially prominent, appearing in the oldest poetic works, such as *Los Milagros de Nuestra Señora*, by the thirteenth-century poet Gonzalo de Berceo, and the fourteenth-century work *Libro de Buen Amor*, by Arcipreste de Hita, not forgetting that beautiful romance, by an unknown hand, in which a captive, languishing in the darkness of his prison cell, roundly curses the crossbowman who has killed the small bird which told him when it was day. Later, the *alondras* take over from the *calandrias* in Spanish literature, receiving in their turn abundant attention from poets, from Juan Meléndez Valdés to Antonio Machado and Gerardo Diego. By way of paying brief homage to other European literature, it is relevant to close this section by quoting from the immortal verses of Goethe's *Faustus*:

"Es ist wohl jedem eingeboren,
daß sein Gefühl hinauf und vorwärts dringt,
wenn über ihm, im blauen Raum verloren,
ihr schemetternd Lied die Lerche singt".

*This **Calandra Lark** has just fed one of its chicks a large invertebrate. Indeed, invertebrates make up the bulk of food intake in nestlings of all but the most granivorous of larks. At least in temperate regions, adults also themselves consume many insects during the breeding season. This seasonal dietary preference seems to be related to energy content, water content, and the requirement of chicks for non-plant matter to supply the proteins necessary for growth; of course, it is also relevant that invertebrates are less readily available in the colder months.*

[*Melanocorypha calandra calandra*, La Rioja, Spain. Photo: José Luis Gómez de Francisco]

Nestling larks grow very rapidly, almost as fast as is physiologically possible. After only 7-8 days the legs of this juvenile ***Red-capped Lark*** *are sufficiently well developed for it to vacate the nest. It will be another week before this particular lark can fly, but adults prefer to scatter the brood as soon as possible, and thus minimize the likelihood of all their offspring being predated together. Juveniles remain dependent for roughly a month before leaving the natal territory altogether. When lark broods are threatened, both adults may perform a distraction display wherein they flutter, feign injury, or wing-clap near the ground.*

[Innate to all, 'tis surely true,
that the heart, uplifted, onward soars
when up aloft, lost in the blue,
its ringing song the lark outpours]

The poetic and musical inspiration lent by larks to humanity has not saved them from persistent persecution, for very material reasons. Sometimes, the desire has been to imprison them as cagebirds, for their songs, as has often been the fate of the Calandra Lark in Mediterranean countries, but often they have simply been eaten. In the words of the popular French song, *Alouette, gentille alouette, alouette, je te plumerai*, a translation of which would run "lark, sweet lark, I shall pluck you". Eurasian Skylarks, in particular, have suffered much hunting in Europe, this being due to their former abundance and to their gregariousness on passage and in winter. Greek vases from the sixth century BC depict scenes of lark-hunting, and such birds were the typical target in the Middle Ages for falconers flying the Merlin, referred to as the ladies' hawk in some countries, or the Eurasian Hobby (*Falco subbuteo*). Larks have been taken with nooses, traps and a variety of nets, as well as with shotguns, often after being attracted by imitations of their calls with whistles and, latterly, recordings, or by using tethered owls (Strigidae). A further method of attracting larks is the use of what are termed "lark mirrors", rotatable devices covered with multiple strips of mirror which reflect the sun. These have been widely employed in many parts of Europe, hence the French term *miroir*, the Spanish *espejuelo* and the German *Lerchenspiegel*, among others. The attractiveness of these mirrors to larks has been much debated, but the reason for it remains unknown; there are those who consider that the reflections may be mistaken for a water spring or a puddle, but, as already noted (see General Habits), larks hardly ever visit drinking places and they appear not to bathe in water. Another traditional hunting technique is nocturnal, and involves the using of a spotlight in order to dazzle the birds at their winter roosts; the hunter uses a cow bell so as to fool the birds into believing that he is a cow.

It is clear that larks, however obtained, were in the past consumed in prodigious quantities in Europe. Early in the nineteenth century, in northern Germany, tax receipts at Leipzig market alone indicate that over 5,000,000 larks were sold annually. Meanwhile, London markets received some 400,000 larks in 1854, and at Dieppe, on the other side of the English Channel, the official records for the 1867/68 winter refer to a total of 255,500 birds as having been handled. Lark-hunting was especially intensive in northern Germany, Denmark, the Netherlands and Belgium. Even today, and despite the official protection afforded to larks by European Community legislation, hunting "traditions" are still tolerated in countries farther south, as in Italy and France. It has been estimated that, in 1997, some 1·5 million larks were captured in each of these two countries. In France, where the *pâté d'alouette*, lark pâté, is regarded as an extraordinary delicacy, larks are caught in the south-west in October and November, the hunters taking advantage of the passage of migrants heading for winter quarters in Iberia and the Maghreb region of north-west Africa. Here, in the French departments of Gironde, Landes, Loir-et-Garonne and Pyrénées Atlantiques, they are caught mainly with special nets known as *pantes*.

The seed-eating habit of the Eurasian Skylark, and the losses which this species was supposed to inflict on agriculture, once provided a justification for hunting it, although this specific excuse proved invalid once the birds' diet was investigated scientifically. In fact, the species is likely to do more harm by eating the green parts of crops than by consuming seed. A study in English sugar-beet fields in spring revealed that cotyledons and the first true leaves of the plants made up 62% of the larks' diet there. The same species in Iraq, in winter, has been found to nibble the young leaves of wheat and barley, which may reduce yields a little, and it also causes severe damage in pastures enriched with lucerne (*Medicago*), resulting in losses of the order of 50% both to plant cover and to seed production. In Israel, too, the Eurasian Skylark is officially considered a pest, being accused of causing damage to fields of sprouting lucerne and wheat and also in plant nurseries.

Despite this, larks generally are not great consumers of grain. This is in part because most of them, unlike such birds as sparrows, weavers, queleas (*Quelea*) and New World blackbirds, do not perch on the plant stems. Instead, they content themselves with fallen seed, taken after the harvest, although flocks of Greater Short-toed Larks in Rajasthan, in western India, have been seen to hover over a field of pearl millet in order to peck the panicles and make the grain fall. The literature on the Alaudidae reports

really serious problems only from Sudan, where, around the 1970s, the Bimaculated Lark was causing severe damage to irrigated sorghum plantations in the semi-desert area of El Butana, near Khartoum. The larks, which are only winter visitors there, gathered in flocks of up to 200 and consumed unripe, milky seeds, which they ripped out of the seedheads, as well as mature grain, which they reached by perching on the plants. The problem was tackled with the use of the avicide fenthion, applied mainly by aerial spraying, which reduced the original estimated population of 200,000 birds by barely 10%. Also in Sudan, the species has been accused of digging up recently planted seed, but, bearing in mind that sorghum is planted in June, whereas the larks do not arrive until October, when the plants are well grown, this charge would not seem to be sustainable.

Status and Conservation

Alaudids provide examples of practically the full range of avian population sizes. Some number many millions of pairs, while others can muster only a few hundred, the differences generally reflecting the very variable extents of their geographical distributions. At one extreme there is the Horned Lark, of Holarctic distribution and arguably one of the world's most abundant passerines. At the other there are several highly localized African species, the future propects of which must give serious cause for concern. Many lark populations are closely affected by human agricultural and pastoral activity, as a result of the modifications which these have imposed upon their habitats.

Lark population densities tend to be relatively low, primarily because of the low productivity which is typical of the open and more or less arid habitats which they generally occupy. Those inhabiting the more productive mesic regions attain higher densities. For example, the Eurasian Skylark in England occurs at between 0·1 and 0·5 pairs per hectare on arable farmland and reaches up to 0·7 pairs per hectare on coastal sand dunes. Similarly, favourable habitats in Spain yield, again on a hectare basis, up to two or three individuals in the case of the Calandra Lark and the Lesser Short-toed Lark, and up to four or five Greater Short-toed Larks. In contrast, desert-dwelling species are often very thinly spread, and it is sometimes necessary to drive many kilometres just to find a few birds. Nevertheless, the nomadic and gregarious desert species can form considerable concentrations in confined areas, where some sparrow-larks, for example, occur at up to 12·5 pairs per hectare. In any event, larks tend to be among the most abundant members of steppe and desert avian communities, often very noticeably so. It is also the case that, although they may occur at low density, the immense geographical expanses occupied by their favoured habitats of tundra, steppe, savanna, desert and arable land result in many alaudids having large or very large total populations.

BirdLife International's *Threatened Birds of the World*, published in 2000, classifies only eight lark species as globally threatened. Since the Alaudidae numbers nearly 100 species, this implies a relatively favourable situation for the family as a whole, given that some 13% of all the world's bird species are considered to be under threat. Furthermore, no larks are known to have become extinct in recent centuries. The eight threatened alaudids are all Afrotropical taxa, and all of them occupy very small, perhaps relict, geographical ranges. Four are from the north-eastern arid zone; these are Ash's Lark (*Mirafra ashi*), the Degodi Lark, Archer's Lark and the Sidamo Lark. A further three, Rudd's Lark, Botha's Lark (*Spizocorys fringillaris*) and the Red Lark, are restricted to the extreme south of the region. The eighth species, the Raso Lark, occupies another "corner of Africa", the volcanic Cape Verde Islands, situated in the eastern Atlantic Ocean 460-830 km west of Senegal; it is a strange lark, formerly placed in the genus *Spizocorys* but now included in *Alauda*. It is very odd that all three species in the very interesting genus *Heteromirafra*, the Archer's, Sidamo and Rudd's Larks, should be among those considered to be at risk. With regard to categories of threat, two species, Rudd's Lark and the Raso Lark, are listed as Critical; two more, Ash's Lark and Botha's Lark, are Endangered; and the remaining four are classed as Vulnerable.

According to BirdLife International, habitat loss or degradation is the principal threat to seven of the eight globally threatened lark species. The exception is the Raso Lark of the Cape Verdes, which occupies an uninhabited islet, of scarcely 7 km² in extent, which is variously named Raza, Razo or Raso. Its total population is very small and fluctuates considerably from year to year, in response, apparently, to the highly variable amount of rainfall. It may number barely 40 birds in drought years, but may rise to 250 in others. In the last reported census, in 2002, be-

*The **Degodi Lark** is restricted to an area of south Ethiopia classified as the Jubba and Shabeelle Valleys EBA. It is thought to number less than 1000 individuals, but this is based on an almost complete lack of evidence. It is very poorly known and no surveys have been undertaken, partly because of security issues within its range. It is one of several larks for which the difficulty of surveying and protecting land in north-east Africa is a chronic problem. Decades of famine, civil war and banditry have severely handicapped conservation action, and in this uncertain situation the Degodi Lark undeniably deserves its rating as Vulnerable.*

[*Mirafra degodiensis*, Bogol Manya, Ethiopia. Photo: Göran Alstedt/ Windrush]

Oddly enough, all three members of the genus Heteromirafra *are threatened with extinction. In view of the disjunction in their ranges, it seems likely that they may be survivors of an ancient lark lineage. One of them, the* ***Sidamo Lark****, is known from only two sites in the South Ethiopian Highlands EBA, and is classed as Vulnerable. The only global estimate of numbers available, 2500-10,000 individuals, is arrived at largely on the basis of inference, and intensive field research is needed. One factor to be kept in mind is that, like other members of the genus, it is difficult to find when males are not calling.*

[*Heteromirafra sidamoensis*, Negele, Ethiopia. Photo: Göran Ekström]

tween 128 and 138 individuals were recorded, of which 61% were males. This uneven sex ratio is possibly related to the sexual dimorphism in bill structure, the bill being longer in males than in females, and to the consequent differences between the sexes in feeding and in the ability to exploit the food available at the time (see Morphological Aspects), although it is worth recalling that imbalances in sex ratios seem to be frequent among larks (see Breeding). The islet is a nature reserve, at least on paper, but it is feared that the fishermen who visit to collect seabird eggs may accidentally introduce such predators as rats (*Rattus*), cats or dogs, which could prove fatal to such a small population. As it is, a near-endemic gecko of the genus *Tarentola* has recently been identified as possibly a serious raider of nests.

Rudd's Lark, the other Critically Endangered alaudid, is patchily distributed in the highland grasslands of South Africa, where its total range covers probably less than 500 km^2. Its habitat, of moderately to heavily grazed humid pastures, receiving over 600 mm of rain annually and situated at altitudes of 1600-1800 m, is under threat of conversion to arable land. The establishment of a Grassland Biosphere Reserve around Wakkerstroom and Volksrust is proposed, and this could afford protection to about 85% of the species' population. The reserve would, in addition, protect important numbers of Botha's Lark, also a species of high pastures and one which is threatened both by agriculture and by afforestation. The third threatened South African species, the Red Lark, occupies a very different habitat, the red sand dunes of the northern Cape Province. The principal problem there is domestic livestock, especially sheep, which damage the fragile dune vegetation by overgrazing and trampling.

In addition to the eight globally threatened lark species, three others are categorized as Near-threatened. All three are confined to the southern parts of Africa. The Melodious Lark has a fragmented range in South Africa, with smaller populations in Zimbabwe and Botswana. Much of its grassland habitat has already been lost to farming and development, and in some parts of its range the remaining areas are heavily grazed. The Agulhas Long-billed Lark is found only in South Africa, where its apparently small total population is restricted to the western Cape. Much of the region in which it occurs has been converted to wheat fields and pasture. Although the lark seems to be fairly well adapted to these unnatural habitats, and may even have benefited from the conversion of the original land, it remains patchily distributed within its range, for reasons unknown. Very little is known about this species' ecology and any potential threats which it may face.

The last of the three Near-threatened species, Sclater's Lark, inhabits arid and semi-arid stony and gravelly plains with scattered grasses and shrubs in the Northern Cape and southern Namibia. Again, it has a highly fragmented range and is generally uncommon and local. In some areas it shows a strong preference for specific sites, where it breeds every year. At the edge of its range, however, its appearance is far less predictable and it seems to lead a nomadic existence, moving in response to rainfall patterns. There is, as yet, no evidence that the populations of Sclater's Lark have declined, but it is thought that increased grazing pressure could have a serious impact on this lark's numbers.

Lack of information is a fundamental problem affecting the protection of threatened African larks, especially those of the north-east, where the dangers posed by the semi-permanent states of war in recent decades must be added to the habitual problems of difficulty of access. Extremely little is known about the one Endangered and three Vulnerable species of this region with regard to their current distributions, their numbers and population trends, their ecology and their conservation problems. The secretive Archer's Lark was discovered in 1922, in Somalia, but it has been seen only once since then, in 1955, nearly half a century ago. The other three were first collected relatively recently, Ash's Lark in 1981, also in Somalia, and the Sidamo Lark and the Degodi Lark both in Ethiopia in, respectively, 1968 and 1971. Many years passed before these three alaudids were again observed in the field, and such sightings have been very few and confined to the type localities or their immediate vicinities.

Absence of information is also reflected in the conservation category of Data-deficient, in which three more African larks are placed. One of these, the Obbia Lark (*Spizocorys obbiensis*), is found only on vegetated sand dunes along the central coastal strip of eastern Somalia, whereas Williams's Lark (*Mirafra williamsi*) is confined to north and central Kenya and Friedmann's Lark has a highly fragmented distribution in East Africa, from south Ethiopia southwards to north Tanzania. The Obbia Lark was reportedly abundant within its small range, but lack of recent surveys hampers any true assessment of its current status. Its apparent reliance on one particular habitat type, of limited extent, would presumably render it vulnerable to any loss or severe degradation of the dune biotope. Williams's Lark lives in rocky desert plains with short grass and low shrubs in the north of its range, but inhabits stands of low *Barleria* shrubs growing on rocky lava desert in central Kenya. It was first discovered in 1955, and in the half-century since then little has been documented with re-

gard to its breeding biology, ecology, distribution and population size. The widely scattered populations of Friedmann's Lark seem to prefer denser grassland with bushes, possibly shunning drier areas, but this is a very poorly known species. It appears certainly to be rare, with very few documented records, most of these from Tsavo National Park, in south-east Kenya, and the adjacent Mkomazi Game Reserve, in north-east Tanzania.

A better taxonomic understanding of larks, especially African ones, may reveal as yet undiscovered "hidden" species requiring attention from conservationists. This may well apply to Beesley's Lark (*Chersomanes beesleyi*) of northern Tanzania, which K. Barnes and N. and L. Baker have recently identified as a new species, genetically distinct from the slightly larger Spike-heeled Lark, with which it had been considered conspecific. Beesley's Lark is found nearly 2000 km to the north of the nearest populations of the latter, and would appear to number barely 100-300 individuals, all confined to two small areas of grassland, subject to heavy grazing and trampling by cattle, in the rainshadows of Mount Kilimanjaro and Mount Meru. Assuming that the taxonomic status of Beesley's Lark is confirmed, this alaudid, instead of representing an interesting disjunct population of a relatively common species, becomes a new Tanzanian endemic and probably the one which is most in need of attention. It is likely to merit the conservation status of Endangered, or even Critical. There is clearly an urgent requirement for both taxonomic and field studies in order to clarify the status of this and other larks.

Some subspecies of alaudids are in serious difficulty. One of these is the nominate race of the Lesser Short-toed Lark, restricted to Tenerife, in the Canary Islands, where it has been driven to the brink of extinction by loss of habitat and by introduced predators. Only two breeding pairs survived in 2002, both within the precincts of Los Rodeos international airport, in the north of the island, in addition to a few captive individuals with which, as a final resort, it is intended to establish a captive-breeding programme. The importance of such a programme is highlighted by the fact that, in 2003, none remained in the Los Rodeos area, although in the south there was still a very small population, numbering fewer than 15 pairs; some doubts had been expressed as to whether these belonged to the nominate race, but a recent genetic study has shown no difference from the latter. Similarly, the endemic Hungarian race *hungarica* of the Greater Short-toed Lark seems to be highly endangered, as the known population within its isolated range numbers only some ten pairs. These are apparently boosted by periodical influxes, a fact which casts serious doubts on the validity of the taxon.

Very few measures are in place to protect threatened larks, and such conservation initiatives often encounter serious difficulties. The siting of potential reserves in arid zones is problematic. In the Karoo, South Africa, protection from overgrazing is regarded as of vital importance, as livestock damages the vegetation to the extent that sheltered nest-sites are eliminated and arthropod abundance is reduced, so much so that the larks' breeding success can fall to zero. Nevertheless, protecting specific sites is ineffective, because these larks are generally nomadic, dependent on habitat patches which flourish briefly after rains and are consequently erratic in both space and time. Relationships between alaudids and livestock may be very different elsewhere, as has been found in Arizona, USA, where a comparison between two similar *mesas* (steep-sided, flat-topped hills), one a livestock ranch and the other ungrazed for many years, revealed that Horned Lark densities were nearly five times higher in the former than in the latter; in other words, grazing had a highly beneficial impact on the larks. A clear relationship between lark populations and vegetation structure has been identified on other occasions, and there is no doubt that the protection of certain species demands a better understanding of the response of vegetation to different grazing pressures. In north Germany, for example, overgrazing by sheep in an area of saltmarsh in Schleswig-Holstein was responsible for a 93% decline in the local population of the Eurasian Skylark over a period of just 13 years.

Moreover, the effects of predation on reproductive success need to be understood. A good example is provided by the situation in the reserve of Las Amoladeras, in the Spanish province of Almería, which was established in order to protect Dupont's Lark, the Thekla Lark and the Lesser Short-toed Lark, among other species. The strict protection regime led to a spectacular growth in the population of rabbits (*Oryctolagus cuniculus*), and these, in turn, attracted numerous foxes (*Vulpes vulpes*) and dogs, the opportunistic foraging of which resulted in an enormous increase in mortality among nesting larks. The reserve became converted into a population sink, apparently dependent for its larks solely, and ironically, on continuous immigration from neighbouring, unprotected zones.

Much more work is currently being undertaken on the conservation of European larks, especially the Eurasian Skylark, than

Like several other larks found on the iron-rich sands of south-western Africa, the ***Red Lark*** *has deep rufous upperparts which provide it with beautiful camouflage. This species is confined to a small area of red sands and clayey soils in Bushmanland. As a result of its small range and low total population of some 10,000 birds, it is currently classed as Vulnerable. Its preferred habitat is susceptible to overgrazing by cattle and other livestock, with local extinction already recorded from some parts of its range.*

[*Calendulauda burra*, Pofadder, Bushmanland, Northern Cape, South Africa. Photo: Andy & Gill Swash]

on the globally threatened species. The fact that this formerly abundant skylark should now find itself in the "Red Books" of such countries as the United Kingdom and the Netherlands is somewhat alarming, and this has triggered numerous studies and a significant increase in our knowledge of this species, and of the biology and ecology of larks in general. Populations of Eurasian Skylarks in Finland, Denmark, Germany, the Netherlands, Britain and France, at least, have been reduced to less than half of their former numbers in the space of twenty years. This apparently inexorable decline, at a rate of over 2% per year, can undoubtedly be attributed to the intensification of modern agriculture, a particular and especially harmful feature of which is the progressive replacement of spring-sown cereals by winter sowing. Such crops as winter wheat provide suitable habitat at the start of the breeding season, in April, but later, once the crops are taller than 20-25 cm, the larks abandon them and settle in tramlines, set-aside zones and other places where, unfortunately, predation is much higher than it is within the fields proper. In general, Eurasian Skylarks prefer sites where the vegetation is neither too tall nor too dense, probably because it affords them a wider field of view and allows them to move more freely when foraging. It has been noted in some places that, within cultivated areas, the larks tend to select fallow fields or patches of stunted growth, which may result from particular topographic or geological features such as karst zones, stony ground and ephemeral pools. Unfortunately, though, the increased use of fertilizers is another feature of intensive agriculture, and this leads to taller and more tightly packed growth on the one hand and to the reduction or elimination of fallow fields on the other. Intensification results in larger fields and a reduction in crop diversity, which is also detrimental to the larks, as they prefer to include three or four different land-use types within their territories. Increased application of insecticides and herbicides is also typical of modern agriculture, and these biocides, obviously, reduce the populations of the insect and weed species on which larks depend for food. With regard to food supplies, the substitution of spring-sown cereals by winter-sown ones has proved to be very deleterious, since only the former produce the stubble fields which are a favourite feeding habitat in winter for larks flocks, which exploit the large quantities of fallen grain available there. These and several other factors have combined to achieve what hunting on a massive scale never did: the endangering of the populations of Eurasian Skylarks. It is paradoxical indeed that this lark, the fortunes of which in Europe grew in historic times with the expansion of agriculture, is now seen as a "flagship species" of a conservation campaign which aims to achieve the fundamental reform of the European Union's Common Agricultural Policy (CAP), and to forestall what is coming to be known as the "Second Silent Spring".

Iberia still boasts a number of more showy flagship species, such as the Great Bustard (*Otis tarda*) and the Pin-tailed Sandgrouse (*Pterocles alchata*), which will also be invoked in this campaign, but even in Iberia several lark species are in some difficulty. The most recent edition of the Spanish Red Book, for example, lists three alaudids: Dupont's Lark is considered "Endangered", the Greater Short-toed Lark is "Vulnerable" and the Lesser Short-toed Lark is "Near-threatened". The negative trends exhibited by these and other larks seem to be due to losses or degradation of long-term fallows and shrub-steppes, resulting from such activities as the ploughing of wastelands, irrigation, the abandonment of grazing, and afforestation.

The value of the Eurasian Skylark as a hunters' target species, combined with its insignificant impact on agriculture and, perhaps, a yearning for its much-loved song, so exalted by the romantic poets of the time (see Relationship with Man), led many nineteenth-century European colonists to introduce the species to other, often far-flung parts of the globe. Skylarks were transported to many places in North America, among them Long Island, New York, where it is known that larks bred in 1887 but became extinct by 1913. They still persist, however, on Vancouver Island, in western Canada, where they were brought from Britain in 1903 at the behest of the British Columbia Natural History Society. The birds prospered there and attained a population of nearly 1000 individuals by the 1960s, when they spread to the neighbouring island of San Juan, in Washington state, USA. Since then, loss of habitat to urban development has reduced the population to barely 30 or 40 pairs, nearly all of them at or near Victoria international airport. The skylarks introduced in Hawaii have had better fortune and now occupy every major island in that group except Kauai, ranging from sea-level to altitudes of over 3000 m. The Eurasian Skylark abounds in south-eastern Australia, around the cities of Adelaide, Melbourne and Sydney, as well as in Tasmania. Finally, New Zealand received 964 skylarks from Britain, in various shipments between 1864 and 1875; by 1900, the species was well established throughout the entire country, and it remains so today. All of these introductions, harmless though they may seem, must be regretted, as should those involving any exotic species anywhere, but especially when places as ecologically unique and fragile as Hawaii or New Zealand are involved.

There can be no doubt that, in today's world, an ever-sharper link exists between the ecology and populations of birds, on the one hand, and ongoing changes in the human socio-economic background, on the other. There is no better example of this among the Alaudidae than that afforded by the Crested Lark. This is a

The South African Grasslands EBA is home to two very rare larks. The commoner of these, ***Botha's Lark****, has a population of 1500-5000 individuals, and is currently treated as Endangered. Not only is it not found in any officially protected area, but its range falls almost entirely within privately owned land, so the success of conservation action hinges on effective communication and co-operation with landowners. Fortunately, it prefers short grassland with bare areas, and is thus favoured by grazing.*

[*Spizocorys fringillaris*,

***Rudd's Lark** is patchily distributed, with a total range of less than 500 km². Even within the core of its range in the eastern Free State and around Wakkerstroom it is localized and thinly spread, although quite why this should be remains unclear. It prefers a mix of moderately and heavily grazed pastures lying at 1600-1800 m above sea-level, and receiving over 600 mm of rain per annum. Sadly, this habitat is threatened by agriculture and afforestation. The proposed Grassland Biosphere Reserve centred on Wakkerstroom and Volkrust would go some way towards protecting a unique grassland ecosystem.*

[*Heteromirafra ruddi*, Wakkerstroom, Kwa-Zulu Natal, South Africa. Photo: Warwick Tarboton]

widely distributed species, essentially an inhabitant of steppe habitats and, in the case of some of its subspecies, true deserts. In Europe, it was traditionally associated with farmland, but here it frequented not so much the fields of crops but, rather, their shrubby margins, as well as tracks and roadsides and the outskirts of villages. The Crested Lark underwent a spectacular northward expansion throughout the nineteenth century and during the early years of the twentieth century, eventually colonizing places as far north as southern Scandinavia. It took advantage, it would seem, of the expansion of the road network, where it fed on insects and semi-digested grain in horse dung, and of industrial and urban development, which gave rise to places of a steppe-like aspect such as building sites, railway stations, airfields, industrial parks, gravel pits and rubbish dumps. It colonized many city centres, making use of Second World War bombsites, and scrounging tamely for food scraps alongside the sparrows in public places. In the last few decades, however, the Crested Lark has experienced a reversal in its fortunes and it now finds itself in retreat, having already disappeared from countries such as Norway, Sweden and Switzerland, and with only a token presence remaining in others, such as Germany. In Niedersachsen, for example, its population in 1998 was estimated at about 1% of that in 1966. The numerous factors invoked to explain this decline include the replacement of horses by motor vehicles, the trend for high-density building, acid rain, climate change and, not surprisingly, changes in farming practices. This last seems to have had a particularly harmful impact on the habitat of the Crested Lark as a consequence of the excessive use of nitrogenous fertilizers. Wastelands which were previously suitable have become overgrown with tall weed growth, producing damper environments and cooler ground temperatures, both of which appear to have a very negative impact on the lark's reproductive success. It is probably habitat scarcity that has made it increasingly common for Crested Larks in Central Europe to be seen to make use of traffic roundabouts and the central reservations of motorways; in recent years, they have, moreover, started to nest on flat rooftops, in some cases, as has been recorded in Moravia, even 14 floors up. These larks, denizens of the steppes but now finding refuge atop high buildings, point to the sad destiny which our implacable transformation of the environment is imposing upon the natural world.

*Of all larks, the **Raso Lark** is perhaps the most likely to slide into extinction. Restricted to the island of Raso, some 500 km off the coast of Senegal, the population fluctuates between 40 and 250 individuals. It cannot increase above this limit because of the island's size (roughly 7 km²). This effectively renders the species highly vulnerable to prolonged drought, or to the accidental introduction of mammalian predators, such as cats or rats. As such, it is classed as Critical and requires constant monitoring.*

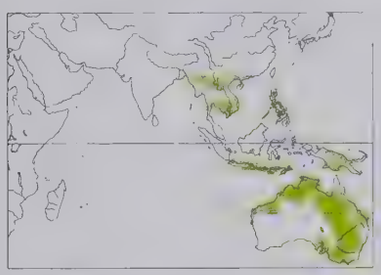
PLATE 53

inches 4

cm 10



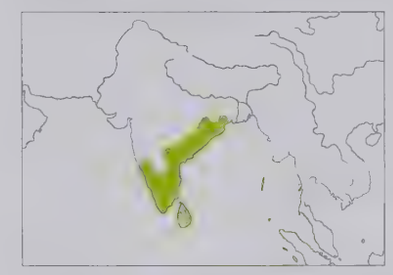
Genus *MIRAFRA* Horsfield, 1821

1. Australasian Bushlark

Mirafra javanica

French: Alouette de Java **German**: Horsfieldlerche **Spanish**: Alondra de Java
Other common names: Australasian Lark, Singing Bushlark(!), Eastern (Singing) Bushlark, Horsfield's Bushlark; Cinnamon Lark (*woodwardi*); Javan Lark (*javanica*)

Taxonomy. *Mirafra Javanica* Horsfield, 1821, Java.
Relationship with African congeners not known. Has sometimes been placed in a superspecies with *M. cantillans*, *M. albicauda*, *M. passerina* and *M. cheniana*, but validity of this grouping remains untested. Often treated as conspecific with *M. cantillans*, and probably closest to and sister-taxon of that species, from which it differs by 1·8% in cytochrome *b* sequences. Geographical variation to some extent correlated with colour of local soil substrate and regional humidity, and there is much presumed convergence in appearance among taxa; only Australian and mainland SE Asian races revised recently, and further study needed. Race *woodwardi* sometimes considered a separate species. Otherwise, described race *beaulieui* (S Vietnam) is synonymized with *williamsoni*, *sepikiana* (N New Guinea) with *aliena*, *subrufescens* (NW Australia) with *forresti*, *normantoni* (NE Australia) with *rufescens*, and *keasti* (SE South Australia) with *horsfieldi*. Sixteen subspecies currently recognized.
Subspecies and Distribution.
M. j. williamsoni Stuart Baker, 1915 - locally in Myanmar, Thailand, Cambodia, Laos, Vietnam and extreme S China (including N Hainan).
M. j. philippinensis R. G. W. Ramsay, 1886 - N Philippines (Luzon, Mindoro).
M. j. mindanensis Hachisuka, 1931 - S Philippines (Negros, Mindanao).
M. j. javanica Horsfield, 1821 - S Borneo, Java and Bali.
M. j. parva Swinhoe, 1871 - Lesser Sundas (Lombok, Sumbawa, Sumba, Flores).
M. j. timorensis Mayr, 1944 - Sawu and Timor.
M. j. aliena Greenway, 1935 – N, NE & S New Guinea.
M. j. melvillensis Mathews, 1912 - Melville I, N Australia.
M. j. halli Bianchi, 1907 - N Western Australia.
M. j. woodwardi Milligan, 1901 - extreme NW Western Australia.
M. j. forresti Mayr & McEvey, 1960 - NE Western Australia.
M. j. soderbergi Mathews, 1921 - N Australia (N Northern Territory).
M. j. rufescens Ingram, 1906 - E Northern Territory, NW Queensland and NE South Australia.
M. j. athertonensis Schodde & Mason, 1999 - NE Queensland (Atherton-Evelyn Tablelands).
M. j. secunda Sharpe, 1890 - S South Australia.
M. j. horsfieldii Gould, 1847 - SE Australia.



Descriptive notes. 13·5-15 cm. Large-billed lark with fairly short tail and wings. Nominate race has fairly indistinct head pattern, with buffish supercilium; rather dark grey-brown above, with heavy but not very contrasting blackish-brown streaks on crown and mantle (but poorly streaked nape), in fresh plumage mantle and scapulars with buffish fringes, notably on edges of inner webs, also blackish-brown upperwing-coverts and tertials with buffish or rufous-buff tips and edges; flight-feathers broadly edged rufous (most noticeable in flight), outer tail feathers extensively white; pale rufous-buff below, more rufous on breast, breast rather sparsely, faintly and finely streaked dark; iris dark brown or dark grey-brown; upper mandible mainly grey, lower mandible pinkish or greyish-yellow; legs dull pink. Differs from *M. cantillans* in darker upperparts. Sexes alike in plumage, female on average smaller. Juvenile differs from adult mainly in having narrow pale buffish tips on crown, back, rump and uppertail-coverts, and lacking broad pale edges of mantle feathers, also has more clearcut pale tips and edges of wing-coverts. Races differ mainly in general plumage coloration and saturation, and strength of streaking: e.g. *woodwardi*, *rufescens*, *melvillensis*, *athertonensis* and *secunda* are notably rufous-tinged, while especially *halli* and *horsfieldii* are markedly grey above and pale buffish below. Voice. Song, either from perch (usually not high) or in towering song flight, of rather short, varied strophes (frequently including imitations of other birds) generally delivered at intervals of c. 1-2 seconds, may continue for lengthy periods. Sharp, rapid, almost explosive alarm calls.
Habitat. Favours open habitats, such as grasslands with scattered bushes and trees, stubble fields and fallow cultivation. Lowlands and middle elevations; to 1680 m in New Guinea.
Food and Feeding. Poorly known. Takes seeds (especially of Gramineae) and insects, e.g. beetles (Coleoptera), ants (Formicidae) and caterpillars. Forages on ground, singly, in pairs or in small, loose groups.
Breeding. Little studied. Season in SE Asia probably mid-Feb or late Feb to at least late Jul; Sept-Apr in Australia (Sept-Jan in S, in N timing depends on onset of rains). Hovering song flight high in sky, with stiff, quivering wings and folded tail. Nest in depression on ground, generally sheltered by tussock, made of grass and rootlets, sometimes hair included, either open or partly or completely domed. Clutch 2-4 eggs; no information on incubation and fledging periods; reports that both sexes incubate require confirmation.
Movements. Mainly sedentary or, at least in Australia, locally and regionally nomadic.
Status and Conservation. Not globally threatened. Locally fairly common through much of range; uncommon in Philippines. No population estimates available for any region.
Bibliography. 2. Jerdon's Bushlark

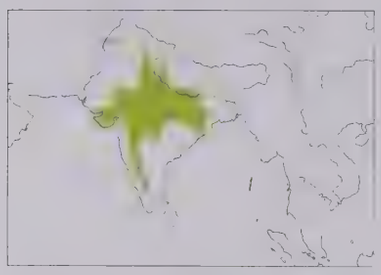
Mirafra affinis

French: Alouette du Dekkan **German**: Jerdonlerche **Spanish**: Alondra de Jerdon
Other common names: Rufous-winged Bushlark; Ceylon Bushlark ("*ceylonensis*")

Taxonomy. *Mirafra affinis* Blyth, 1845, southern India.
Relationship with African congeners unknown. Recently split from *M. assamica* on basis of pronounced differences in, especially, vocalizations, song flight, other behaviour, habitat choice, and cytochrome *b* gene sequences (13·4%); equally large genetic (respectively, 13·7% and 15·1%) and vocal differences from *M. erythrocephala* and *M. microptera*, both of which were also previously merged with *M. assamica*. Sri Lankan population often separated as race *ceylonensis*; further study needed. Monotypic.
Distribution. E & S India and Sri Lanka.

Descriptive notes. 13·5-15 cm. Heavy-bodied lark with large bill, short tail and wings, and rather long legs. Has relatively narrow supercilium, usually buffish in front of eye, paler buffish or whitish above and behind eye; ear-coverts pale grey-brown with inconspicuous dark eyestripe and dark streaks at rear (generally forming dark rear border), variably distinct whitish band on side of nape/rearmost ear-coverts; crown, nape and mantle rufescent grey-brown, heavily streaked; dark grey-brown or blackish-brown upperwing-coverts and tertials with buffish or rufous-buff tips and edges; remiges dark grey-brown or blackish-brown, broad rufous edges of primaries forming prominent patch (most noticeable in flight); tail dark grey-brown, buffy outer edges of, especially, outermost pair of rectrices; underparts buffish (paler when plumage worn), heavy blackish spots on breast; upper mandible mostly dark grey, lower mandible mostly pinkish; legs pinkish. Best separated from *M. erythroptera* by shorter tail, more heavily streaked upperparts (which usually less rufous-tinged in area of sympatry), also slightly longer bill and legs, less distinct head pattern, more buffish underparts (when fresh), darker-centred tertials, wing-coverts and central tail feathers, and less rufous in wings (in flight). Sexes alike in plumage, female on average smaller. Juvenile differs from adult mainly in more extensive and more clearcut dark centres and narrow pale buffish tips on crown, mantle and scapulars. Voice. Diagnostic song a drawn-out, dry, metallic rattle, "zizizizezezezezezezezezezezezezezezezezezeze", delivered from ground or, more often, from perch in top of bush, tree, on telephone wire, fence post etc., at times also in song flight. Calls a thin, drawn-out whistle and a short, thin rattle.
Habitat. Variety of open habitats, such as fallow fields with bushes and trees along margins, and scrub-covered rocky ground, to c. 1500 m. Also commonly in habitats with plenty of scrub, bamboo thickets and trees, such as forest edges, and even in scrubby glades in open forest. Frequently lands in trees when flushed.
Food and Feeding. Diet poorly known; seeds and invertebrates taken.
Breeding. Little studied. Season Dec-May, chiefly from Mar, in India; Mar-Aug/Sept, mainly May, in Sri Lanka. In short, low song flight, male ascends some metres, and then descends with wings held in shallow V-shape, tail spread, legs dangling. Nest a cup of grass, often domed, placed in depression on ground, frequently under a stone or bush. Clutch 3-4 eggs; no information on incubation and fledging periods.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally common throughout range. In Sri Lanka, more numerous in dry zone. No population estimates available.
Bibliography. Abdulali (1978), Ali (1969), Ali & Ripley (1987), Alström (1998, 2002), Alström *et al.* (2004), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Grimmett *et al.* (1998), Rasmussen & Anderton (2004), Ripley (1982), Srinivasulu & Srinivasulu (1997), Stuart Baker (1926, 1935), Vaurie (1951a).



3. Indian Bushlark

Mirafra erythroptera

French: Alouette à ailes rousses **German**: Rotflügellerche **Spanish**: Alondra India
Other common names: Indian/Red-winged(!) Lark, Indian Red-winged/Rusty-winged Lark/Bushlark

Taxonomy. *Mirafra erythroptera* Blyth, 1845, northern portion of Indian Peninsula.
Relationship with African congeners unknown. Mitochondrial DNA data suggest that this species is nested within the "*M. assamica* complex", thus making latter non-monophyletic. Birds from NW of range, supposedly paler and greyer above and whiter below, sometimes recognized as race *sindiana*, but variation apparently individual rather than geographical; others, from Rajkot, in Gujarat (India), described as race *furva* on basis of longer tail and darker plumage than that form; more research needed. Monotypic.
Distribution. SE (possibly also NE) Pakistan and much of India (S Punjab, W Rajasthan and W Gujarat E to Orissa, S to S Karnataka).
Descriptive notes. 13·5-15 cm. Heavy-bodied, large-billed lark with short wings, rather short tail, moderate-length legs. Has prominent whitish or pale buffish supercilium, and band of same colour on nape side/rear ear-coverts (often widening to form whitish patch just below rear of supercilium); crown, nape and upperparts rufescent grey-brown, rather heavily streaked; upperwing-coverts and tertials medium or dark grey-brown with buffish edges; distinctively rufous flight-feathers with

On following pages: 4. Indochinese Bushlark (*Mirafra erythrocephala*); 5. Bengal Bushlark (*Mirafra assamica*); 6. Burmese Bushlark (*Mirafra microptera*); 7. Madagascar Lark (*Mirafra hova*); 8. Singing Bushlark (*Mirafra cantillans*); 9. White-tailed Lark (*Mirafra albicauda*); 10. Kordofan Lark (*Mirafra cordofanica*); 11. Williams's Lark (*Mirafra williamsi*); 12. Rusty Lark (*Mirafra rufa*); 13. Monotonous Lark (*Mirafra passerina*); 14. Melodious Lark (*Mirafra cheniana*); 15. Friedmann's Lark (*Mirafra pulpa*); 16. Ash's Lark (*Mirafra ashi*); 17. Somali Long-billed Lark (*Mirafra somalica*); 18. Red-winged Lark (*Mirafra hypermetra*).

dark tips (most noticeable in flight); tail mostly blackish, central feathers browner, outer edge of outermost pair buffish or buffish-white; whitish or pale buffish underside, breast with large blackish-brown spots; iris warm brown; bill mostly pinkish, grey culmen; legs pink. Differs from *M. affinis* primarily in having longer tail and less heavily streaked upperparts (which usually more rufous-tinged in area of sympatry), also slightly shorter bill and legs, more distinct head pattern, whiter underparts (when fresh), paler-centred tertials, wing-coverts and central tail feathers, and more rufous in wings (in flight); from *M. assamica* in overall paler and more contrastingly patterned plumage. Sexes alike in plumage, female on average smaller. Juvenile has more extensive and more clearcut dark feather centres and more distinct pale buffish tips on crown, mantle and scapulars. Voice. Song, given from ground or low perch or in short, low flight, consists of clear whistles alternating in length and pitch, frequently more drawn-out towards end of strophe; an uncommon song type, delivered in more prolonged song flight, is a rambling mixture of typical song notes and calls. Calls with drawn-out whistles and rattles, often combined.

Habitat. Arid, preferably somewhat scrubby and often rocky areas in lowlands.

Food and Feeding. Diet poorly known; seeds and invertebrates taken.

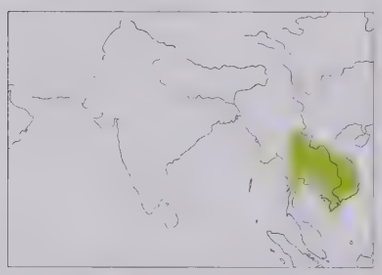
Breeding. Little studied. Mar-Oct, probably mainly May-Jul; often, perhaps usually, at least two broods. In common type of song flight, male rises some metres, then descends with wings slightly raised, tail spread, legs dangling. Nest, believed built mostly by female, a cup of grass, often domed, placed in depression on ground, frequently under a stone or bush. Clutch 3-4 eggs, occasionally 2; female believed to undertake most of incubation, assisted by male, male assists also in feeding of young; incubation and fledging periods not documented.

Movements. Sedentary; possibly some short-distance movements. May be only non-breeding visitor to NE Pakistan.

Status and Conservation. Not globally threatened. Widespread and locally common in most of range. No population estimates. Status in NE Pakistan (Salt Range) uncertain; further fieldwork required.

Bibliography. Ali (1996), Ali & Ripley (1987), Alström (2002), Alström et al. (2004), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Grimmett et al. (1998), Kirkpatrick (1954a), Mukherjee (1995), Pätzold (1994, 2003), Rasmussen & Anderton (2004), Ripley (1982), Roberts (1992), Santharam (1980), Shukla & Shrivastava (1985), Stuart Baker (1926, 1935), Vaurie (1951a).

4. Indochinese Bushlark



Mirafra erythrocephala

French: Alouette d'Indochine **German**: Indochinalerche **Spanish**: Alondra Indochina
Other common names: Rufous-winged Bushlark, Bush Lark

Taxonomy. *Mirafra erythrocephala* Salvadori and Giglioli, 1885, Cochinchina.

Specific name frequently given as *marionae*, but that is predated by present name. Relationship with African congeners unknown. Recently split from *M. assamica* on basis mainly of pronounced differences in vocalizations, song flight, other behaviour, habitat choice and cytochrome *b* gene sequences (14·8%); equally large genetic (respectively, 13·7% and 11·7%) and vocal differences from *M. affinis* and *M. microptera*, both of which were also previously considered conspecific with *M. assamica*. Birds from NW Thailand sometimes separated as race *subsessor*. Monotypic.

Distribution. S Myanmar (Tenasserim), Thailand (except most of peninsula and extreme SE), Cambodia, S & C Laos and S Vietnam.

Descriptive notes. c. 15 cm. Heavy-bodied lark with large bill, short tail and wings, rather long legs. Has whitish supercilium, pale buffish-brown ear-coverts with fairly distinct streaking and quite distinct dark eyestripe and rear border, usually a thin whitish band across upper nape; rather dark greyish-brown or brown-grey above, crown usually more rufous-tinged, crown, mantle and scapulars rather heavily streaked; wings dark grey-brown or blackish-brown, upperwing-coverts and tertials with buffish or rufous-buffish tips and edges, broad rufous edges of primaries forming prominent patch (most noticeable in flight); tail dark grey-brown with indistinct rufous-tinged outer edges, widest on outermost rectrix; underparts dingy buffish, breast heavily dark-spotted; upper mandible mostly dark grey, lower mandible mostly pinkish; legs pinkish. Distinguished from very similar *M. microptera* by darker, greyer, less distinctly streaked upperparts, slightly darker and dingier underparts, whiter supercilium, less buffish and more distinctly streaked ear-coverts, and whitish nuchal band. Sexes alike in plumage, female on average smaller. Juvenile differs mainly in having more extensive and more distinct dark centres and narrow pale tips on crown, mantle and scapulars. Voice. Song quick series of thin, clear, mostly drawn-out notes, arranged in strophes of c. 2-8 seconds in duration, given from ground or, more often, from elevated perch, sometimes in flight. Calls a high-pitched, metallic "tirrrrrrrrrrrrrrrrrrrrrrrr" rattle, also short series of thin, high-pitched, highly variable whistles, often combined with the rattle.

Habitat. Various open, dry areas with scattered trees and bushes, including cultivation, also forest edge with plentiful scrub, bamboo thickets and trees; to 900 m. Often flies to nearby tree perch when flushed.

Food and Feeding. Nothing known of diet; probably similar to that of *M. assamica* and other close relatives.

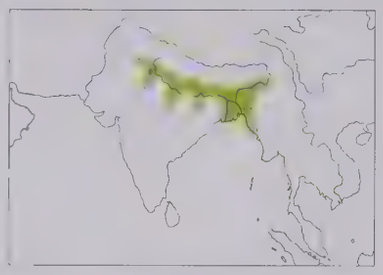
Breeding. Not studied. Season Mar-Aug. Male has short, low song flight, in which he rises some metres, then descends with wings slightly raised, tail spread, legs dangling. No other relevant information available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Locally common throughout range. No population estimates.

Bibliography. Alström (1998, 2002), Alström *et al.* (2004), Deignan (1945), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Duckworth *et al.* (1999), Eames & Robson (1992), Lekagul & Round (1991), Robson (2000), Violani & Barbagli (1999).

5. Bengal Bushlark



Mirafra assamica

French: Alouette d'Assam **German**: Bengalenlerche **Spanish**: Alondra de Assam
Other common names: Bush Lark, Rufous-winged Lark/Bushlark, Collared Lark(!)

Taxonomy. *Mirafra Assamica* Horsfield, 1840, Assam, India.

Relationship with African congeners unknown. Formerly treated as a polytypic species, including *M. affinis*, *M. erythrocephala* and *M. microptera* as races, but differs from all those in vocalizations, song flight, other aspects of behaviour and habitat choice. Mitochondrial DNA data suggest that the "*M. assamica* complex" is non-monophyletic, since *M. erythroptera* is nested within this group, and also that the various taxa diverged a considerably longer time ago than is indicated by the rather small morphological differences (pairwise genetic divergences in the cytochrome *b* gene 11·7-15·1%). More distantly related to *M. javanica* and *M. cantillans*. Monotypic.

Distribution. N India and S Nepal E to Bhutan, Bangladesh and extreme W Myanmar.

Descriptive notes. 16 cm. Heavy-bodied lark with large bill, short tail and wings, rather long legs. Has buffish supercilium (greyish-white when plumage worn); rather dark brown-grey or grey-brown above, crown, mantle and scapulars with moderately distinct dark streaks, nape indistinctly streaked; wings dark grey-brown or blackish-brown, upperwing-coverts and tertials with buffish or rufous-buffish tips and edges, broad rufous edges of primaries forming prominent rufous patch (most noticeable in flight); tail dark grey-brown, outer web of outermost rectrix rufous-buff (pale buffish when worn); underparts rufous-buff (paler when worn), breast with moderately heavy dark streaks; iris brown; bill mostly dark grey above and pinkish below; legs pink. Distinguished from e.g. *M. affinis*, *M. microptera* and *M. erythroptera* in overall darker and less contrastingly patterned plumage. Sexes alike in plumage, female on average smaller. Juvenile differs mainly in showing more extensive and more clearcut dark centres and narrow pale tips on crown, mantle and scapulars. Voice. Song a characteristic monotonous repetition of a thin, slightly harsh, squeaky, disyllabic note, usually given in flight; less common song, mainly from ground or low perch, rarely in flight, a jingle of short, varied notes and mimicry. Call a short, explosive series of mainly high-pitched notes.

Habitat. Open grassland and fields in plains, generally, but not necessarily, with scattered bushes and trees; sometimes rather wet. Almost entirely terrestrial.

Food and Feeding. Diet poorly known; includes seeds and invertebrates.

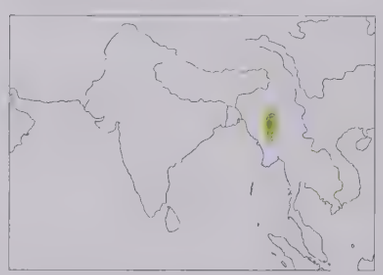
Breeding. Little studied. Mar-Aug, mainly May and Jun. Male has high, undulating, sustained song flight, flies in random "circles", alternating quick wingbeats with short glides on spread and slightly raised wings and spread tail. Nest a cup of grass, sometimes domed, in depression on ground. Clutch 3-4 eggs; incubation and fledging periods not documented.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Widespread and locally common throughout range. No population estimates.

Bibliography. Abdulali (1976), Ali & Ripley (1987), Alström (1998, 2002), Alström *et al.* (2004), Ball (1874, 1878), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Grimmett *et al.* (1998), Inskipp & Inskipp (1991), Khan (1988), Macdonald (1906), McClure (1998), Pätzold (1994, 2003), Rasmussen & Anderton (2004), Ripley (1982), Robson (2000), Sharma (1994), Singh (1994), Smythies (1986), Stuart Baker (1926, 1935), Vaurie (1951a).

6. Burmese Bushlark



Mirafra microptera

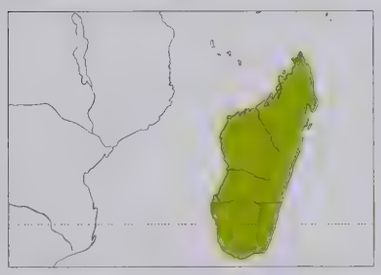
French: Alouette de Birmanie **German**: Burmalerche **Spanish**: Alondra Birmana
Other common names: Rufous-winged Bushlark

Taxonomy. *Mirafra microptera* Hume, 1873, Thayetmyo, Myanmar.

Relationship with African congeners unknown. Formerly treated as conspecific with *M. assamica*, but pronounced differences in, especially, vocalizations, song flight, other behaviour, habitat choice, and cytochrome *b* gene sequences (13·2%); equally large genetic (respectively, 15·1% and 11·7%) and vocal differences from *M. affinis* and *M. erythrocephala*, both of which were also previously considered conspecific with *M. assamica*. Monotypic.

Distribution. C Myanmar.

Descriptive notes. 13·5-15 cm. Heavy-bodied, large-billed lark with short tail and wings, rather long legs. Has prominent buffish supercilium, buffish-brown ear-coverts (usually with dark eyestripe and rear border), whitish band on nape side/rearmost ear-coverts (often widening to form a whitish patch just below rear of supercilium); warm brownish-buff or rufescent grey-brown above, crown, nape, mantle and scapulars heavily streaked; wings dark grey-brown or blackish-brown, upperwing-coverts and tertials with buffish or rufous-buffish tips and edges, broad rufous edges of primaries forming prominent rufous patch (most noticeable in flight); blackish outer tail feathers with pale buffish or buffish-white outer web of outermost rectrix; underparts very pale buffish or whitish, breast heavily dark-spotted; bill mostly dark grey above and pinkish below; tarsus and toes pinkish. Distinguished from *M. affinis* by paler and more uniform underparts, more contrasting black breast spots, slightly more distinct head pattern; from *M. erythrocephala* mainly by paler, browner, more distinctly streaked upperparts, paler and cleaner underparts, more buffish supercilium, more buffish and less streaked ear-coverts, no thin whitish nuchal band. Sexes alike, female on average smaller. Juvenile undescribed. Voice. Three different song types: commonest a short, hurried jingle of varied high-pitched whistles, given from perch (often rather high); another type is series of high-pitched, mostly drawn-out whistles, given in short, low song flight, or from ground, or from low perch; third type,



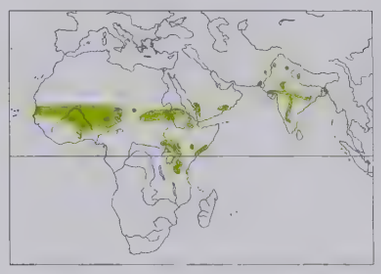
basically like first but with longer strophes and shorter pauses, given in high, prolonged song flight, frequently ends (during descent) with second song type. Commonest calls a short high-pitched "heep" and a series of high-pitched whistled rattles.
Habitat. Open areas with scattered bushes and trees, including cultivation, also more barren habitats such as sandy fallow fields. Frequently perches in trees, and on telephone wires and buildings (e.g. ancient temple ruins).
Food and Feeding. No information on diet; probably similar to that of *M. assamica* and other close relatives.
Breeding. Little studied. Often begins in late Mar, but probably mainly from May-Jun, and may continue until Oct. Male has sustained, high song flight, flies in erratic "circles" with quick, slightly jerky wingbeats and spread tail, rarely also very short glides on spread wings; also short, low song flight, rises some metres, then descends with wings slightly raised, tail spread, legs dangling. Nest a domed cup of grass with side entrance, on ground, often sheltered by tuft of grass, clod of earth or small bush. Clutch 2-4 eggs; incubation and fledging periods not documented.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Locally common to very common, but has small range. No population estimates available.
Bibliography. Alström (1998, 2002), Alström *et al.* (2004), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Robson (2000).

7. Madagascar Lark

Mirafra hova

French: Alouette malgache **German**: Hovalerche **Spanish**: Alondra Malgache
Other common names: Madagascar Bushlark, Hova Lark

Taxonomy. *Mirafra hova* Hartlaub, 1860, St Augustine Bay, Madagascar.
Relationships uncertain; exhibits close affinities to smaller congeners of Africa and Asia. On other hand, has been suggested as belonging in genus *Calandrella*. Monotypic.
Distribution. Madagascar.



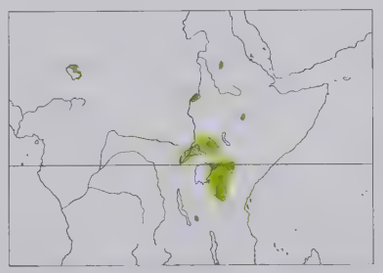
Descriptive notes. 13 cm. Rather small, compact lark with shortish, stout bill. Plumage is pale brown, streaked dark brown, above, contour feathers having buff fringes in fresh plumage (but these often worn away); prominent crown streaking contrasts with broad, pale grey-brown to buffy supercilium; narrow dark eyestripe, and broader moustachial stripe forking under eye and forming distinctive "teardrop" mark; flight-feathers brown with narrow paler fringes; underparts whitish to pale buff, breast with heavy dark streaking, flanks and undertail-coverts washed darker buff; eyes dark brown; bill pinkish to orange-flesh, sometimes with darker grey upper half of maxilla; legs pale, pinkish-flesh to brownish-flesh. Sexes alike. Juvenile undescribed; probably more boldly patterned, with pale feather fringes above and spotted, rather than streaked, breast. Voice. Male has varied, musical song, typically delivered in display-flight, also from perch or even on ground.
Habitat. Virtually any open habitat, ranging from grassland and dry shrubland to open woodland, and roads; from sea-level to at least 2500 m.
Food and Feeding. Diet little recorded; seeds, e.g. grass seeds and rice, and insects, including grasshoppers (Acrididae). Forages on ground, occasionally digging with bill or gleaning from low vegetation. Occurs in small groups of 3-6 individuals when not breeding.
Breeding. Breeding occurs throughout the year. Monogamous. Male advertises territory primarily through aerial display, circling, or flying into the wind, at up to 150 m above ground. Nest an open bowl, lined with fine grasses, built in shallow depression in ground at base of a grass tuft or against a piece of wood, with "apron" of wood, bark or mud clumps around nest edge (especially on unsheltered side). Clutch 2 eggs; no information on incubation and fledging periods; when disturbed at nest, adult often feigns injury, scurrying away with wings fluttering or half-spread.
Movements. Little known; presumably mostly resident.
Status and Conservation. Not globally threatened. Common to abundant throughout Madagascar. Has almost certainly benefited from forest clearance, and has adapted to agricultural lands, including dry rice paddies.
Bibliography. Benson *et al.* (1976-1977), Collin & Collin (1996), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Langrand (1995), Milon *et al.* (1973), Ramanitra (1995), Rand (1936), Sinclair & Langrand (1998), van Someren (1947), Young (1995).

8. Singing Bushlark

Mirafra cantillans

French: Alouette chanteuse **German**: Buschlerche **Spanish**: Alondra Cantarina
Other common names: Singing Lark, Western Singing Bushlark; African Singing Bushlark (*chadensis*, *marginata*)

Taxonomy. *Mirafra cantillans* Blyth, 1845, India.
Has been placed in a superspecies with *M. javanica*, *M. albicauda*, *M. passerina* and *M. cheniana*, but validity of this grouping remains untested. Frequently treated as conspecific with *M. javanica*, and probably closest to and sister-taxon of that species, from which it differs by 1·8% in cytochrome *b* sequences. Some evidence that disjunct nominate race of Indian Subcontinent is distinct from the Afrotropical populations; further study needed. Four subspecies recognized.
Subspecies and Distribution.
M. c. chadensis Alexander, 1908 - Sahel zone of Africa from Senegal E to W Eritrea.
M. c. marginata Hawker, 1898 - S Eritrea, NE Ethiopia, NW & S Somalia, S Sudan, NE Uganda, NW, C & S Kenya and NE Tanzania.
M. c. simplex (Heuglin, 1868) - SW Saudi Arabia, Yemen and W Oman.
M. c. cantillans Blyth, 1845 - N & S Pakistan, India, W Nepal and SE Bangladesh.
Descriptive notes. 13 cm; 15-21 g. Small, compact lark with shortish, stubby bill. Nominate race has prominent whitish or pale buff supercilium contrasting with brownish-buff ear-coverts, latter further accentuated by pale collar separating them from rather dark, heavily streaked neck side; crown and upperparts grey-brown and streaked, mantle and back with broad pale feather edges (less conspicuous in worn plumage); flight-feathers have narrow rufous or sandy-buff margins



(can be lost with wear); tail grey-brown, white outer feathers (obvious in flight); throat white, rest of underparts pale buff, breast browner with small darker spots (variable, spotting sometimes indistinct or lacking); eyes dark brown; bill pinkish-horn, darker and greyer on upper mandible; legs fleshy pink. Distinguished from e.g. *M. assamica*, *M. affinis* and *M. microptera* mainly by much more extensive white in tail, less obvious rufous wing patches and, typically, less heavily streaked breast. Sexes alike. Juvenile has broad pale fringes above, more diffuse, rounded spotting on breast. Races differ primarily in plumage tone and extent of streaking: *simplex* has upperparts somewhat warmer and browner; *marginata* is slightly darker above, more heavily streaked on sides of breast; *chadensis* is paler, more sandy-coloured and less heavily streaked above. Voice. Male's song a varied series of chirps, whistles and buzzes, elements repeated in different combinations, but typically ends with buzzy trill, given either from low perch or ground in series lasting 5-10 seconds, or more or less continuously during aerial display; in Indian Subcontinent (nominate race) song more varied, with longer elements and frequent changes in pace, also accomplished mimicry incorporating song elements of almost all other species found in same range (African races not known to mimic other species). Usually silent when flushed.
Habitat. Fairly short grassland and open acacia (*Acacia*) savanna; also in cultivated land, provided that crops are short and dense enough to provide cover. In Yemen, recorded mostly in cultivated areas. In Africa, breeds in areas of taller, dry grass that have not been burnt recently. Lowlands and foothills.
Food and Feeding. Food a mix of insects and seeds (mostly of grasses). Stomach contents of birds from Senegal mainly insects, with grasshoppers (Acrididae) 85% (mostly instars of *Oedalus senegalensis*), beetles (Coleoptera) 7% and seeds only 5%, also small numbers of caterpillars and solifugids. Seeds increased in diet after crops sprayed for control of insect pests. Forages on ground, picking food from ground surface or gleaning from low vegetation; occasionally digs with bill. Grit regular in stomachs, with greater abundance and frequency in juveniles. When flushed, frequently hovers briefly before dropping almost vertically back into grass.
Breeding. Breeding synchronized with local rains; mostly May-Oct in Sahel (nesting commenced within 6 days of rain in N Senegal), and Nov-Jan and Apr-Jun in E Africa; Mar-Sept (mostly Jun-Sept) in Indian Subcontinent. Probably monogamous. Male advertises territory by aerial or perched singing, has protracted aerial display with single flights lasting 40 minutes or longer. Nest a shallow cup built of grasses, lined with fine vegetation, on ground, usually next to or under a grass tuft, usually with partial or complete dome woven into the tuft; in Senegal, most nests face N or NE, away from prevailing winds (which bend grass tufts towards N, but also provide shade). Clutch 2-4 eggs (mean 3·6 in Africa); no information on parental duties or incubation and fledgling periods. In Senegal study success was low, with hatching 15-24% and fledging 49-55%, giving overall breeding success of 7-13%; predation was thought to be main cause of failure.
Movements. Poorly understood. Sahel population assumed to be partly migratory, at least in W Africa, with post-breeding movement S into more mesic savanna during dry season. Moves into semi-arid areas of E Africa following good rains, but unclear whether this is migration or simply nomadism; scattered records from C Tanzania all outside breeding season, suggesting dispersal S after breeding, as occurs with other species (e.g. *Eremopterix leucotis*). May be only summer visitor in Oman. In Indian Subcontinent some short local movements reported, but little information.
Status and Conservation. Not globally threatened. Locally common or even abundant in Africa; very local in Indian Subcontinent, where scarce in Pakistan and rare in Nepal, frequent but very localized in India. Relative abundance often difficult to assess, as this species is easily overlooked when not displaying; creeps on the ground and is reluctant to flush. Densities of 2-4 males/ha in Africa, but species is patchy and not predictable in many areas. Probably adversely affected locally by poor grazing practices, but it remains common within much of its extensive range. Its reliance on semi-arid areas for breeding results in comparatively little suitable habitat being lost to cultivation.

Ali (1996), Ali & Ripley (1987), Alström (2002), Archer & Godman (1937-1961), Ash (1992b), Ash & Miskell (1998), Bannerman (1953), Barlow *et al.* (1997), Borrow & Demey (2001), Byaruhanga *et al.* (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Grimmett *et al.* (1998), Jennings (1995), Jones (1991), Keith *et al.* (1992), Lees-Smith (1986), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1970), Morel (1981), Mukherjee (1995), Mullié & Keith (1991, 1993), Nikolaus (1987), Porter *et al.* (1996), Ripley (1982), Roberts (1992), Sagar Baral (1998), Short *et al.* (1990), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

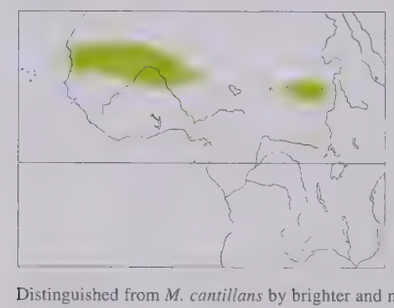
9. White-tailed Lark

Mirafra albicauda

French: Alouette à queue blanche **German**: Weißschwanzlerche **Spanish**: Alondra Coliblanca
Other common names: White-tailed Bushlark, Northern White-tailed Lark/Bushlark

Taxonomy. *Mirafra albicauda* Reichenow, 1891, Gonda, Tabora District, Tanzania.
Has been placed in a superspecies with *M. javanica*, *M. cantillans*, *M. passerina* and *M. cheniana*, although this grouping remains to be tested. Apparently isolated population in SW Tanzania originally separated as race *rukwensis*, but this treatment considered unwarranted. Monotypic.
Distribution. Locally in Chad (L Chad), E Sudan, SC Ethiopia, NE DRCongo, Uganda, NW & SW Kenya and N & SW Tanzania.

Descriptive notes. 13 cm; 20-25 g. Small, compact lark with shortish, stout bill. Has prominent pale lores and supercilium, contrasting with brownish ear-coverts, latter separated from rather heavily streaked neck side by pale collar; crown and upperparts dark grey-brown with broad blackish feather centers, in fresh plumage mantle and back with contrasting paler buff-brown margins, imparting streaked appearance; flight-feathers have pale rufous-buff margins; tail grey-brown, outer feathers with much white; throat white, rest of underparts pale buff, heavily streaked dark on breast; eyes dark brown; bill dark slate above, pale



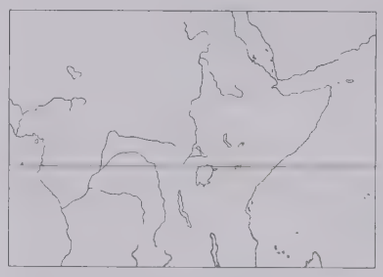
pinkish below, looks slightly upturned; legs flesh-brown. Distinguished from *M. cantillans* (of race *marginata*) by darker appearance of upperparts, more heavily streaked breast, more distinctly two-toned bill, less rufous-looking remiges in flight; from *M. pulpa* by blacker feather centres on upperparts, lacking rufous tones, slightly larger bill. Sexes alike. Juvenile has pale fringes on upperparts, appearing scaled. VOICE. Male display song a long, rambling series of chirps and whistles, less varied than that of *M. cantillans* and typically lacking latter's bubbling trills.
Habitat. Prefers dense, fairly short grassland, usually on black-cotton soils; often found around lake margins. Typically avoids open areas.
Food and Feeding. Food includes insects, e.g. grasshoppers (Acrididae), also seeds and other vegetable matter. Forages terrestrially, picking food from ground or gleaning from low vegetation. When flushed, flies a short distance and then drops sharply into dense grass, much as *M. cantillans*.
Breeding. Recorded Mar-May. Male sings in protracted aerial display, circling over territory and then dropping steeply to ground. Nest a shallow cup lined with dry grass, placed on ground, usually next to a grass tuft, often at edge of fairly open area in dense grassland; apparently does not build dome over nest, but in muddy sites nest may have a distinct mud rim. Clutch 2 eggs, but few nests found; no information on parental duties or incubation and fledging periods.
Movements. Little known. Probably resident.
Status and Conservation. Not globally threatened. Generally uncommon; locally common in parts of E Africa. Often hard to observe on ground and, except when displaying, is easily overlooked. No evidence of habitat loss, but agriculture has probably had adverse effect on the species in at least some areas.
Bibliography. Ash (1992b), Bannerman (1953), Borrow & Demey (2001), Butler (1905), Byaruhanga *et al.* (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1970), Nikolaus (1987), Safford (1993), Short *et al.* (1990), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Vesey-Fitzgerald (1957), Zimmerman *et al.* (1996).

10. Kordofan Lark

Mirafra cordofanica

French: Alouette du Kordofan **German**: Kordofanlerche **Spanish**: Alondra del Kordofán
Other common names: Kordofan Bushlark, Golden Lark

Taxonomy. *Mirafra cordofanica* Strickland, 1852, Kordofan, Sudan.
Monotypic.
Distribution. Mauritania and N Senegal E to Mali, N Burkina Faso and W Niger, also E Chad and C Sudan.



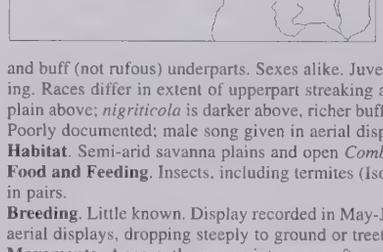
Descriptive notes. 14 cm. Fairly small, compact lark with distinctive golden-rufous upperparts only lightly streaked darker brown. Has buffish-white supercilium and face with only narrow dark eyestripe, giving pale-faced appearance (enhanced by whitish bill); in fresh plumage, some back feathers have narrow pale fringes and darker subterminal bars; tail blackish, central feathers golden-rufous and outer tail white (distinctive in flight); underparts pale whitish-buff, breast washed darker and with a few diffuse darker streaks; eyes dark brown; bill pale whitish horn, slightly darker tip and dorsal side of upper mandible; legs flesh-pink. Distinguished from *M. cantillans* by brighter and more rufous appearance of upperparts, with less distinct streaking, and more striking tricoloured tail. Sexes alike. Juvenile has broader pale feather fringes on back and wing-coverts, heavier dark spotting on breast. VOICE. Male song a series of varied notes, including chirps, whistles and trills, similar to that of *M. cantillans* but with less repetition, given from low perch or ground as well as in aerial display; includes some mimicry of other birds, including ducks (Anatidae), bee-eaters (*Merops*), woodpeckers (Picidae) and prinias (*Prinia*), mostly in aerial display.
Habitat. Arid areas; occurs on red sands in sandy soils with scattered grasses and shrubs. Often associated with specific grasses, including *Stipagrostis uniplumis*, *Cenchrus biflorus* and *Schoenefeldia gracilis*.
Food and Feeding. Seeds and insects; forages on ground.
Breeding. Very little known. Displaying reported May-Aug, associated with summer rains in the Sahel; in Burkina Faso, singing occurred despite absence of rain, when adjacent *M. cantillans* were silent. Male song flight up to 100 m above ground, lasts for up to 35 minutes. Nest and eggs undescribed; distraction displays observed in Mauritania.
Movements. Poorly known. Probably opportunistically nomadic, moving in response to local rain events, but at least some birds make more or less regular movements S into more mesic areas in winter months.
Status and Conservation. Not globally threatened. Uncommon or rare throughout range. No documented records from E Niger and W Chad, but it may occur sporadically throughout this area. Although no specific threats identified, increasing grazing pressure in the Sahel is likely to affect this species adversely.
Bibliography. Bannerman (1953), Borrow & Demey (2001), Butler (1905), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Fishpool *et al.* (2000), Gee (1984), Giraudoux *et al.* (1988), Keith *et al.* (1992), Lynes (1924), Mackworth-Praed & Grant (1960, 1970), Portier *et al.* (2002), Salvan (1968), Sinclair & Ryan (2003), Snow & Perrins (1998).

11. Williams's Lark

Mirafra williamsi

French: Alouette de Williams **German**: Williamslerche **Spanish**: Alondra de Williams
Other common names: Williams's Bushlark, Marsabit Lark

Taxonomy. *Mirafra williamsi* Macdonald, 1956, Marsabit, Kenya.
Monotypic.
Distribution. Locally in N & C Kenya (Dida Galgalu Desert, N of Marsabit, and between Isiolo and Garba Tula).
Descriptive notes. 14 cm. Fairly small, compact, heavy-billed lark with relatively plain upperparts. Has strongly marked head, with pale supercilium and neck-collar contrasting sharply with dark, rich brown ear-coverts; crown dark-streaked rufous, upperparts rich brown with prominent paler rufous feather edges, especially on wing-coverts and flight-feathers; tail brown, outer feathers



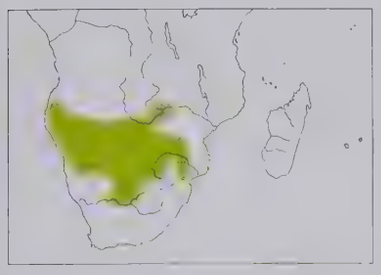
white; buffy white below, breast washed rufous and variably streaked and mottled dark brown and chestnut; eyes dark brown; bill grey-horn above, lower mandible whitish; legs pale flesh. Rarer variant ("dark morph") is almost uniform blackish-brown above. Rufous type distinguished from *M. albicauda*, *M. pulpa* and *M. cantillans* by overall more rufous appearance, especially across breast, with much less streaking above, from *Calendulauda alopex* by slightly smaller size, plainer, less rufous upperparts, appreciably heavier bill and less white in tail; dark form best told from *M. albicauda* by darker breast, heavier bill. Sexes alike. Juvenile undescribed. VOICE. Male song a series of thin, rather scratchy notes, with distinctive "tsir-ééét tsir-ééét" towards end of each series.
Habitat. The two populations are found in slightly different habitats: in N (N of Marsabit) occurs on rocky desert plains and red lava soils with scattered short grass and low shrubs; in S (Isiolo) occupies uniform areas of low *Barleria* shrubs in rocky desert. Altitudinal range 650-1300 m.
Food and Feeding. Food includes seeds and insects. Forages singly on ground, rarely perching on rocks.
Breeding. Males display before sunrise, making low, laboured display-flights. Nest and eggs undescribed.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Data-deficient. Locally common, but has small and restricted range; known from only two areas in N & C Kenya. Secretive, and easily overlooked. Nothing is known about any changes in its population size, or any potential threats to its habitat.
Bibliography. Bennun & Njoroge (1999), Collar & Stuart (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Hockey (1997a), Keith *et al.* (1992), Lewis & Pomeroy (1989), Short *et al.* (1990), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Stevenson & Fanshawe (2002), Turner (1997), Zimmerman *et al.* (1996).

12. Rusty Lark

Mirafra rufa

French: Alouette rousse **German**: Rostlerche **Spanish**: Alondra Rufa
Other common names: Rusty Bushlark

Taxonomy. *Mirafra rufa* Lynes, 1920, Juga Juga, 3000 feet [c. 915 m], 15 miles [c. 24 km] ENE of El Fasher, Darfur, Sudan.
Has been suggested by some authors as forming a superspecies with *M. gilletti*, but no data on molecular genetics for either species; *Calendulauda poecilosterna* (when placed in present genus) suggested as third member of same superspecies. Three subspecies recognized.
Subspecies and Distribution.
M. r. nigriticola Bates, 1932 - E Mali E to WC Niger.
M. r. rufa Lynes, 1920 - SC Chad and W Sudan.
M. r. lynesi C. H. B. Grant & Mackworth-Praed, 1933 - C Sudan.



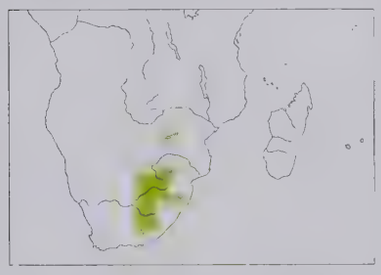
Descriptive notes. 13-15 cm. Small to medium-sized lark with narrow buff supercilium, dark-streaked rufous ear-coverts. Nominate race has crown and upperparts rufous, variably streaked black and buff; tail blackish, central pair of feathers rufous, narrow buff edges of outer feathers (visible at close range); underparts buffy, throat slightly paler, breast streaked and mottled darker brown and rufous; eyes red-brown; bill blackish-horn above, whitish lower mandible; legs grey-brown. Distinguished from other small congeners by slightly longer tail lacking white sides, from more similar *M. rufocinnamomea* by somewhat paler upperside and buff (not rufous) underparts. Sexes alike. Juvenile is paler above with more prominent streaking. Races differ in extent of upperpart streaking and intensity of plumage tones: *lynesi* is almost plain above; *nigriticola* is darker above, richer buff below, with heavier streaking on breast. VOICE. Poorly documented; male song given in aerial display, described as "pleasing".
Habitat. Semi-arid savanna plains and open *Combretum* woodland on rocky ridges.
Food and Feeding. Insects, including termites (Isoptera), and seeds. Forages on ground, singly or in pairs.
Breeding. Little known. Display recorded in May-Jul, also Sept in Chad. Male performs protracted aerial displays, dropping steeply to ground or treetop perch. Nest and eggs undescribed.
Movements. Apparently moves into areas after rain, but this possibly a reflection of its greater conspicuousness when displaying. Single record of race *nigriticola* in N Togo perhaps indicative of some larger-scale movements, but not known whether these are at all regular.
Status and Conservation. Not globally threatened. Locally common in some parts of range, but generally scarce. A poorly known species.
Bibliography. Bannerman (1953), Bates (1934), Borrow & Demey (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Giraudoux *et al.* (1988), Keith *et al.* (1992), Lynes (1924), Mackworth-Praed & Grant (1960, 1970), Newby (1980), Nikolaus (1987), Salvan (1968), Sinclair & Ryan (2003).

13. Monotonous Lark

Mirafra passerina

French: Alouette monotone **German**: Sperlingslerche **Spanish**: Alondra Monótona
Other common names: Monotonous Bushlark, White-tailed Lark(!)

Taxonomy. *Mirafra passerina* Gyldenstolpe, 1926, Damaraland, Namibia.
Sometimes placed in a superspecies with *M. javanica*, *M. cantillans*, *M. albicauda* and *M. cheniana*, but validity of this grouping remains untested. Monotypic.
Distribution. S Angola E to SW Zambia and W Zimbabwe, S to C Namibia, Botswana and NC & NE South Africa.



Descriptive notes. 14 cm; 21-28 g. Medium-small, compact, stout-billed lark with relatively plain, unmarked face. Has buffy supercilium barely contrasting with buffish-brown ear-coverts; buffy brown above, streaked darker brown, with rufous edges of flight-feathers forming rufous wingpanel; white outer tail feathers; throat and belly white (white throat prominent when singing), breast contrastingly buffy with a few dark brown streaks; eyes dark brown; bill dark horn above, paler below; legs pinkish. Differs from *M. cheniana* in slightly larger size, less distinct facial markings. Sexes alike. Juvenile is darker above, with buff-fringed feathers, appearing scaly, has breast more heavily spotted. Voice. Male song a short series of rapid, rather croaky notes run together, variously rendered as "for-syrup-is-sweet" or "tell-it-to-him", each phrase lasting less than 1 second, song repeated monotonously every 2-5 seconds, usually from perch on top of bush or tree, also in short display-flight.
Habitat. Favours rather arid savanna and woodland, including mopane (*Colophospermum mopane*) and acacia (*Acacia*) woodland; often in areas with sparse grass cover, but found also in denser grassland. After good rainfall, irrupts into semi-desert areas, provided that at least some shrubs present for songposts.
Food and Feeding. Insects, spiders and seeds. Feeds on ground.
Breeding. Breeds during summer rains, Oct-Mar, with peak in Jan. Probably monogamous. Advertising male sings incessantly, day and night, from elevated perch, or in short display flight, rising 15-20 m and then dropping back to perch; singing may cease during hottest part of day, but resumes if clouds cover sun; territory c. 2 ha, but as little as 0·5 ha in some areas. Nest a deep cup enclosed by well-developed domed roof, with side entrance, made from grasses, interior lined with dry grass and stems, almost invariably placed within or against a grass tuft, blades of which typically incorporated into roof. Clutch 2-4 eggs, usually 3; no information on parental duties or incubation and fledging periods.
Movements. Poorly known. Relatively few records outside breeding season, leading to speculation by some authors that it is an intra-African migrant; this, however, seems implausible, given absence of records outside known breeding range; much lower reporting rates throughout range in winter, suggesting no systematic movements take place, and it seems more likely that species is simply overlooked when not calling. Nomadic, irrupts into areas outside core range in years of above-average rainfall. Even within areas where breeding takes place regularly, pairs seldom occupy the same places in successive years; this may be linked to localized rainfall patterns.
Status and Conservation. Not globally threatened. Common to locally abundant after rains; up to 2 pairs/ha in favoured areas. Status at other times of year difficult to assess, as species is probably overlooked when not calling. Probably adversely affected by agriculture, as it avoids crop fields and orchards, but remains common in well-managed rangelands. Also, its savanna habitat is well represented in protected areas; an estimated 500,000 individuals occur in the two largest protected areas in South Africa (Kruger National Park and Kgaligadi Transfrontier Park).
Bibliography. Aspinwall (1976), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), Kemp *et al.* (2001), Mackworth-Praed & Grant (1962), Maclean (1993a), Penry (1994), Sinclair & Hockey (1996), Sinclair & Ryan (2003), Tarboton (2001), Thomson (1983), Vernon (1983b).

14. Melodious Lark

Mirafra cheniana

French: Alouette mélodieuse **German**: Spottlerche **Spanish**: Alondra Melodiosa
Other common names: Latakoo Lark, Southern (Singing) Lark

Taxonomy. *Mirafra cheniana* A. Smith, 1843, no locality = Latakoo, northern South Africa.
Sometimes placed in a superspecies with *M. javanica*, *M. cantillans*, *M. albicauda* and *M. passerina*, but validity of this grouping remains to be tested. Monotypic.
Distribution. C Zimbabwe, SE Botswana and E South Africa.

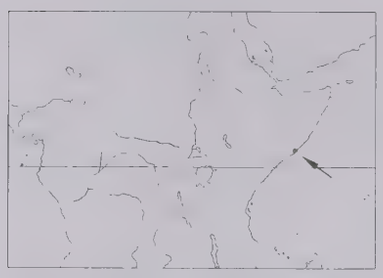
Descriptive notes. 12 cm. Small, fairly compact lark with distinct pale supercilium contrasting with brown ear-coverts. Crown and upperparts are buffy brown, streaked darker brown; flight-feathers have narrow rufous edges, forming rufous panel on folded wing; white outer webs of outer tail feathers; throat white, breast buffy with variable streaking of darker brown, belly creamy buff; eyes brown; bill pale horn; legs pinkish. Distinguished from *M. passerina* by smaller size, more prominent pale supercilium, usually more buffy underparts; from *Spizocorys conirostris* by longer, more slender, horn-coloured bill, longer tail, paler belly. Sexes alike. Juvenile is darker with pale-fringed feathers above, supercilium less marked, bill paler. Voice. Male song, typically delivered in protracted aerial display but also from low perch (including termite mound), long and rambling, surprisingly loud (bird seems closer than it actually is), frequently incorporating calls of e.g. finches (Fringillidae), sunbirds (Nectariniidae), cisticolas (*Cisticola*), plovers (Charadriidae), kites (*Elanus*, *Milvus*), kestrels (*Falco*), pipits (*Anthus*) and swallows (Hirundinidae), as well as other sounds, including hyrax (Procaviidae) alarm calls; at one site six males recorded as mimicking at least 48 birds, and additional 25 species mimicked at other sites; mimetic elements interspersed among basic structure of whistles and trills, each usually repeated 2-4 times, e.g. "chuck-chuck-chuck-ick-ick-ick-trrrrrrrr-eck-eck-errr-errr-errr-chuck-chuck-chuck…"; song becomes shorter as season progresses. Also a soft alarm call, "chuck chuck chucker chuck".
Habitat. Grassland slopes; avoids wetter lowlands. Prefers more open grassland, with open spaces between tussocks, typically where grass less than 50 cm tall. In South Africa found in areas dominated by *Themeda triandra*; in Zimbabwe inhabits areas where *Eragrostis*, *Heteropogon*, *Setaria* and *Loudetia* grasses predominate.
Food and Feeding. Seeds, mostly of grasses, also some insects. Feeds on ground.
Breeding. Sept-Mar (mainly Nov-Jan) in South Africa and Jan-Mar in Zimbabwe. Probably monogamous and territorial; in favoured areas, displaying males spaced 50-100 m apart. In protracted aerial display lasting 30-40 minutes, male sings while climbing steadily from ground, then hangs almost stationary 25-50 m above territory, returning to ground in a series of vertical steps, often singing during each step; sings and displays mostly in morning, on calm days. Nest a domed structure with side entrance, built from coarse grasses, lined with finer grass leaves, placed in shallow depression at base of a grass tuft, or between two tufts, and with distinctive "apron" of grass stems outside entrance; domed roof rather more peaked than in nests of congeners. Clutch 2-4 eggs (mean 2·8); no information on parental duties or incubation and fledging periods.
Movements. Apparently largely resident, but seasonal fluctuations in numbers may indicate some movement; undertakes local movements in response to dry-season fires. Lack of geographical variation across its fragmented range has been interpreted as indicating either that there is sufficient movement to prevent accumulation of regional differences, or that species' range has contracted relatively recently.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted to well-managed grasslands, and hence patchily distributed, with estimated maximum range of 110,000 km². Range has contracted in South Africa in recent years; large areas have been transformed for crop production, as well as by development of urban areas around Johannesburg and Pretoria, and much of the remaining grassland has been degraded by overgrazing; absent from heavily grazed areas. Small, isolated population in Zimbabwe, where currently known from only two sites, both farms listed for resettlement; some habitat in Zimbabwe has been lost as a result of bush encroachment. Known from very few localities in Botswana. This species may also be threatened by climate change, because its preferred grassland habitat requires a specific rainfall regime to prevent it from becoming too dry and invaded by shrubs, or too wet, which is likely to make the grassland too dense.
Bibliography. Barnes (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), English (1995), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Hosken (1990), Hustler & Frost (2002), Keith *et al.* (1992), Mackworth-Praed & Grant (1962), Maclean (1993a), Masterson & Parkes (1993), Robertson (1989), Sinclair & Hockey (1996), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Tarboton (2001), Vernon (1971).

15. Friedmann's Lark

Mirafra pulpa

French: Alouette de Friedmann **German**: Friedmannlerche **Spanish**: Alondra de Friedmann
Other common names: Friedmann's Bushlark, Sagon Lark; Nyiro/Rufous Lark/Bushlark ("*M. candida*")

Taxonomy. *Mirafra pulpa* Friedmann, 1930, Sagan River, Shoa Province, Ethiopia.
Birds from R Nyiro, in NE Kenya, described as species "*M. candida*", but type specimen appears indistinguishable from present species. Monotypic.
Distribution. S Ethiopia, N, C & SE Kenya and NE Tanzania.



Descriptive notes. 13-14 cm; 22 g. Rather small, compact lark. Has pale supercilium, dark-streaked rufous crown; upperparts rufous-looking, with rich rufous and buff edges of feathers, rufous-brown centres of greater coverts, tertials and central tail feathers; rufous wingpanel, white outer tail; white throat (prominent when singing), warm buff below, breast streaked dark brownish; eyes brown; bill dark horn above, paler below, often with pinkish wash; legs dull flesh. Distinguished from extremely similar *M. cantillans* by more rufous appearance above (at close range feather centres rufous-brown, not blackish-brown), heavier streaking on especially nape and mantle, warmer buff underparts, less prominent supercilium, appreciably heavier bill. Sexes alike. Juvenile has broad pale fringes above, breast with diffuse spots rather than streaks; differs from juvenile *M. cantillans* in having more rufous on wings, nape and back. Voice. Song diagnostic, rather stereotyped "hooéééooo" whistle, repeated every 1-2 seconds, quite unlike song of *M. cantillans* and other small larks in its range; given from elevated perch, such as low bush, or in low display-flight.
Habitat. Prefers dense grassland with scattered bushes; recorded also in short, sparse grassland.
Food and Feeding. Grass seeds, also small grasshoppers (Acrididae), beetles (Coleoptera) and other insects. Forages on ground.
Breeding. Little known. Displaying males recorded Nov-Jan and Apr-May; birds in early Aug were in active moult. Low song flight by male, circling 5-10 m above ground, duration usually less than 1 minute; when singing from perch, leans forward with crown feathers raised, throat feathers puffed out; sings and displays throughout day and on moonlit nights; reputed wing-clapping in Ethiopia requires confirmation. Nest and eggs undescribed.
Movements. Assumed to be nomadic or partially migratory, in association with rains. In Kenya, typically recorded in Tsavo only during rainy season, but unclear whether this is because species is much easier to locate when males are displaying; at Ngulia Lodge, two individuals recorded at night in Dec, during trapping of Palearctic migrants.
Status and Conservation. Not globally threatened. Data-deficient. Most records are from Tsavo National Park, in SE Kenya, and adjacent Mkomazi Game Reserve, in NE Tanzania. Is apparently extremely rare, although group of 150 observed in Tsavo West National Park. Uncertain whether great preponderance of records from protected areas is merely a result of greater numbers of observers there, or reflects particular requirements of species that are lacking outside reserves. No specific threats identified, but its preferred habitat of dense grassland is probably prone to overgrazing and to transformation for agriculture.
Bibliography. Ash (1992b), Bennun & Njoroge (1999), Collar & Stuart (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lack (1977, 1997), Lewis & Pomeroy (1989), Pearson *et al.* (1992), Short *et al.* (1990), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

16. Ash's Lark

Mirafra ashi

French: Alouette d'Ash **German**: Ashlerche **Spanish**: Alondra de Ash
Other common names: Ash's Bushlark

Taxonomy. *Mirafra ashi* Colston, 1982, Uarsciek (Uarshek), south Somalia.
Monotypic.
Distribution. E coastal plain of Somalia in area of Uarshek (80 km N of Mogadishu).

Descriptive notes. 17 cm; 31-42 g. Medium-sized to large lark, appearing grey-brown above with only faint wash of rufous. Has narrow, indistinct pale supercilium; in fresh plumage upperparts scaly-looking, with pale fringes and dark subterminal bars; primaries and outer secondaries have rufous margins, forming panel on closed wing; tertials finely barred; tail greyish, rectrices with pale buff margins separated from rest of feather by narrow blackish band, outer tail feathers edged white; underparts whitish, breast and flanks washed pinkish-buff, lower throat and breast faintly streaked rufous-brown, larger and darker streaks at side of breast; eyes dark brown; bill dark grey, paler blue-grey below; legs creamy. Differs from *M. gilletti* in larger size, longer bill and legs, and tail pattern; from *M. somalica* in smaller size, appreciably shorter bill, darker, less rufous and more streaked upperparts, smaller and narrower supercilium not extending far behind eye, narrower white on outer tail. Sexes alike. Juvenile is more heavily streaked above, with broad buffy edges of feathers, slightly richer buff below. Voice. Undescribed; reported as often singing from tops of small bushes.
Habitat. Short, open grassland in stabilized dune systems with a few scattered bushes and fossil coral outcrops.
Food and Feeding. Diet unknown. Runs across open ground between grass tufts; frequently perches on tops of tufts.
Breeding. A female had enlarged ovaries in Jul, but was also in active wing and tail moult. No other information; nest and eggs undescribed.
Movements. Unknown; presumably resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Central Somali Coast EBA. Known to occur only in area just N of Uarshek, where it was reported as locally common in 1980s; almost certainly does not occur farther S, but possibly extends N along coastal plain. Current total range estimated as being 1730 km², with global population of 2500-10,000 individuals and possibly decreasing, but these figures extremely speculative. No recent surveys, but it may be threatened within its tiny range, in which no protected areas exist, by habitat loss and degradation linked to new coastal developments. Conservation targets include fieldwork aimed at determing its total range and status, as well as identifying threats to its habitat. Moreover, this is an extremely poorly known species, with virtually no information on its appearance or behaviour in the field, and no information on its ecology.
Bibliography. 17. Somali Long-billed Lark

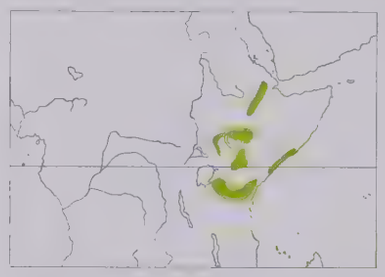
Mirafra somalica

French: Alouette de Somalie **German**: Somaliriesenlerche **Spanish**: Alondra Somalí
Other common names: (Red) Somali Lark, Somali Long-billed Bushlark

Taxonomy. *Certhilauda somalica* Witherby, 1903, Dibbit, Somalia.
Possibly forms a superspecies with *M. hypermetra* and *M. africana*. Suggested that it is allied to *Certhilauda* on basis of structure and undomed nest, but these could be result of convergence; has also been proposed, on basis of limited evidence from displays, that race *rochei* may be a distinct species, with only nominate race belonging in *Certhilauda*. Both races retained in present genus pending sequencing of genetic material and further study. Two subspecies recognized.
Subspecies and Distribution.
M. s. somalica (Witherby, 1903) - N & NE Somalia (S to c. 3° N); probably also extreme E Ethiopia.
M. s. rochei Colston, 1982 - coast of C Somalia (2-3° N).



Descriptive notes. 19-22 cm; 44-50 g. Large reddish lark with long, slender bill; reminiscent of *Certhilauda*, but with rufous edges of flight-feathers. Nominate race has rufous face with darker streaks on ear-coverts, fairly prominent whitish supercilium; crown and upperparts warm rufous-brown, faint white streaks on nape and neck, back feathers with buff on inner edges, rump feathers white-tipped with dark subterminal bar; upperwing-coverts rufous with whitish margins; tertials rufous, edged white, with narrow dark subterminal band; flight-feathers edged rufous; tail dark grey-brown, central pair of feathers rufous-brown with darker central streak and buff edges, white outer web of outer feathers; throat whitish; rest of underparts creamy buff, variable rufous-brown streaking on breast; eyes brown; bill dark horn, base of lower mandible paler; legs whitish or creamy brown. Distinguished from *M. africana* of race *sharpei* by slightly larger size, longer and thinner bill, somewhat paler rufous upperparts, white outer tail, longer and less curved hind claw; from *M. ashi* mainly by larger size, longer bill, paler, more rufous and less streaked upperparts, stronger supercilium. Sexes alike, female on average smaller. Juvenile undescribed. Race *rochei* is darker and more heavily streaked than nominate. Voice. Undescribed; implication that nominate race has a long, clear whistle, similar to that of S African *Certhilauda*; *rochei* reported as singing from tops of bushes in morning and evening.
Habitat. Open grassland, often with open patches of red sand; may occur where there are occasional small shrubs or even a few small trees.
Food and Feeding. Diet unknown. Feeds on ground. Runs rapidly when disturbed, often jumping up on to grass tufts to gain better vantage; when flushed, seldom flies more than 50 m.
Breeding. Little known. Breeding recorded in Jun in N and Sept in S. Apparently solitary or in pairs throughout year. Race *rochei* reported as having short, wing-snapping display-flight up to 5 m above ground. Only one nest described, a shallow scrape in ground next to a grass tuft, virtually unlined but with "apron" of plucked grass around edge. Clutch 3-4 eggs; nothing known about parental duties or incubation and fledging periods.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Reported to be fairly common. Poorly known species; fieldwork required in order to determine its true status, as well as its ecology and biology.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Colston (1982b), Herremans *et al.* (1994), Keith *et al.* (1992), Mackworth-Praed & Grant (1960), White (1956).

18. Red-winged Lark

Mirafra hypermetra

French: Alouette polyglotte **German**: Riesenlerche **Spanish**: Alondra Alirroja
Other common names: Red-winged Bushlark

Taxonomy. *Spilocorydon hypermetrus* Reichenow, 1879, Kibaradja, Tana River, Kenya.
May form a superspecies with *M. africana*, possibly also including *M. somalica*. Sometimes considered conspecific with former, but the two are morphologically and vocally distinct, with no intermediate forms where their ranges meet in Kenya and N Tanzania. Four subspecies recognized.
Subspecies and Distribution.
M. h. gallarum Hartert, 1907 - Ethiopia (Rift Valley S from Awash).
M. h. kathangorensis Cave, 1940 - extreme SE Sudan.
M. h. kidepoensis Macdonald, 1940 - extreme S Sudan and NE Uganda.
M. h. hypermetra (Reichenow, 1879) - Kenya, S Somalia and NE Tanzania.

Descriptive notes. 21-23 cm; 44-68 g. Large, robust lark with fairly long, stout bill and long tail; sometimes shows small crest when singing. Nominate race has prominent buffy supercilium; crown and upperparts rufous-brown (variable, some individuals greyer) and fairly heavily dark-streaked; rufous flight-feathers form rufous panel on folded wing (and conspicuous in flight), although secondaries are browner with paler buff edges; tail feathers brown with buff outer edges (broader in outer tail); underparts variable, rufous to buff, breast with black central steraking passing to dark rufous-brown streaking which coalesces to form dark pectoral patch on breast side (patch often inconspicuous when plumage worn); eyes brown; bill dark greyish-horn above, paler and more pink below; legs pale pink to greyish-white, sometimes brownish-flesh. Distinguished from closely similar *M. africana* by larger size, noticeably longer tail, on average longer bill, and blackish pectoral patches. Sexes alike. Juvenile is darker with pale feather fringes above, has more diffuse spots on breast, reduced dark pectoral patches. Race *kidepoensis* is slightly smaller than nominate, also browner and more chestnut above; *kathangorensis* resembles previous but darker; *gallarum* is paler and greyer, with pectoral patches small or absent. Voice. Song loud, far-carrying whistles, in series 1-15 seconds long (mean 3 seconds), same motif seldom repeated more than five times before switching to new variation, similar to song of *M. africana* but longer and more variable; also protracted song lasting several minutes, including regular mimicry of other birds' calls, one individual recorded as mimicking in 15-minute period 20 species from 16 families, including other larks, cisticolas (*Cisticola*), swallows (Hirundinidae), starlings (Sturnidae), bustards (Otididae), lapwings (*Vanellus*), nightjars (Caprimulgidae), mousebirds (*Colius*), bee-eaters (*Merops*) and hornbills (Bucerotidae), with a single 12-second song containing mimicry of five other species; sings mostly from elevated perch, also from ground and in short display-flight.
Habitat. Savanna and grassland with scattered trees, to 1350 m. Typically in drier habitats and at lower elevations than *M. africana* where their ranges meet; perches on bushes and small trees more often than does that species; the two are not known to co-occur.
Food and Feeding. Insects, including termites (Isoptera), also some seeds. Feeds on ground; occasionally jumps into air in pursuit of flying insects.
Breeding. Breeds in Nov-Jan in E Africa and in Jun in Somalia. Monogamous and territorial, singing throughout year. Male has short, laboured song flight. Nest in shallow scrape on ground at base of a grass tuft, lined with cup of grass and rootlets, these woven into overhanging vegetation to form domed roof. Clutch 1-4 eggs; no information on parental duties or incubation and fledging periods.
Movements. Apparently resident, but may undertake local movements. At Ngulia Lodge, in Kenya, one flew to lights at night in Dec with other nocturnal migrants.
Status and Conservation. Not globally threatened. Locally common in suitable habitat within relatively restricted range.
Bibliography. Ash & Miskell (1998), Bennun & Njoroge (1999), Byaruhanga *et al.* (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1978), Fishpool & Evans (2001), Keith *et al.* (1992), Lack (1985), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Nikolaus (1987), Short *et al.* (1990), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), White (1956, 1960a), Zimmerman *et al.* (1996).

19. Rufous-naped Lark

Mirafra africana

French: Alouette à nuque rousse **German**: Rotnackenlerche **Spanish**: Alondra Nuquirrufa
Other common names: (Red) Somali Lark, Somali Bushlark (*sharpii*)

Taxonomy. *Mirafra africana* A. Smith, 1836, Algoa Bay, Eastern Cape, South Africa.
May form a superspecies with *M. hypermetra*, possibly also including *M. somalica*. Sometimes considered conspecific with former, but the two are morphologically and vocally distinct, with no intermediate forms where their ranges meet in Kenya and N Tanzania. Geographical variation extreme, and future studies likely to reveal that several races, especially among isolated populations in W, C & NE Africa, should be treated as separate species; likely candidates for future splits include *malbranti*, which has a quite distinct aerial display and may be more closely related to *M. angolensis*, and *sharpii*, which has distinctive plumage; conversely, differences among many contiguous races are broadly clinal, and further study may reveal that several taxa are untenable; full review required. Other described races, all considered insufficiently distinct, include *anchietae* (Huíla, in SW Angola), *irwini* (Cuando Cubango, in SE Angola), *zuluensis* (Maputa, in NE KwaZulu-Natal) and *rostrata* (coastal SE South Africa). Twenty-three subspecies tentatively recognized.
Subspecies and Distribution.
M. a. henrici Bates, 1930 - SE Guinea, N Sierra Leone, N Liberia and extreme W Ivory Coast.
M. a. batesi Bannerman, 1923 - SE Niger, W Chad and C (possibly also NE) Nigeria.
M. a. bamendae Serle, 1959 - W Cameroon, possibly also adjacent E Nigeria.
M. a. stresemanni Bannerman, 1923 - C Cameroon (Adamawa Plateau).
M. a. kurrae Lynes, 1923 - W Sudan.
M. a. sharpii Elliot, 1897 - NW Somalia.
M. a. malbranti Chapin, 1946 - E Gabon, SC PRCongo and adjacent SW DRCongo.
M. a. ruwenzoria Kinnear, 1921 - E DRCongo and SW Uganda.
M. a. tropicalis Hartert, 1900 - E Uganda, SW Kenya and NW Tanzania.
M. a. athi Hartert, 1900 - C Kenya and N Tanzania.
M. a. harterti Neumann, 1908 - S Kenya.
M. a. occidentalis (Hartlaub, 1857) - W Angola.
M. a. kabalii C. M. N. White, 1943 - E Angola (Lunda Sul and N Moxico) and NW Zambia (Balovale).
M. a. gomesi C. M. N. White, 1944 - E Angola (E Moxico) and W Zambia (Kabompo).
M. a. chapini C. H. B. Grant & Mackworth-Praed, 1939 - SE DRCongo and NW Zambia.
M. a. nyikae Benson, 1939 - NE Zambia, adjacent SW Tanzania and N Malawi.
M. a. nigrescens Reichenow, 1900 - S Tanzania (Kitulu Plateau).
M. a. isolata Clancey, 1956 - SE Malawi.
M. a. pallida Sharpe, 1902 - S Angola (SW Cuando Cubango) and N Namibia.
M. a. ghansiensis (Roberts, 1932) - E Namibia and W Botswana.
M. a. grisescens Sharpe, 1902 - N Botswana, W Zambia and NW Zimbabwe.
M. a. transvaalensis Hartert, 1900 - S Tanzania and Mozambique S to N South Africa.
M. a. africana A. Smith, 1836 - SE South Africa.

Descriptive notes. 16-20 cm; male 40-55 g, female 33-49 g. Fairly large, robust lark with short erectile crest, rufous flight-feathers forming prominent rufous panel on folded wing (and conspicuous in flight); bill relatively stout for a primarily insectivorous lark. Nominate race has buffish lores and supercilium, with browner ear-coverts; crown dark brown with buff and rufous feather edges (much rufous on hindcrown and nape), hindneck paler; upperparts rufous-brown to brown, streaked, wing-coverts edged rufous and buff; flight-feathers dark brown with rufous at bases and on outer webs; tail dark brown, outer feathers with buff outer webs; throat whitish, rest of underparts rufous to rufous-buff, paler on flanks, breast with dark spots; eyes brown; most of maxilla dark horn to dark grey, with rest of bill paler pinkish, sometimes darker towards tip; legs flesh-pink to straw-coloured. Differs from e.g. *M. angolensis*, *M. apiata*, *M. fasciolata* and *M. rufocinnamomea* in larger size, more robust build, possession of crest; from *M. hypermetra* in being slightly smaller and more compact, with shorter tail, no blackish patch on neck side. Sexes alike. Juvenile typically has darker upperparts with pale feather fringes, larger and more diffuse spots on breast sometimes forming darker pectoral patch. Races vary enormously in plumage colour, and rufous nape is absent or barely visible in many: *transvaalensis* is paler and less streaked above than nominate, paler below; *grisescens* is paler and greyer than previous; *ghansiensis* has pale pinkish-sandy upperparts; *pallida* has upperparts paler, more yellow-brown, variably streaked; *occidentalis* is darker than last, more grey-brown; *chapini* is dark and heavily streaked blackish above, bill larger; *gomesi* is greyer than previous, streaking well defined; *kabalii* is paler, more blue-grey, and less streaked above, bill larger; *malbranti* is remarkably plain, light reddish-brown very little dark streaking above, plain ochre below; *nigrescens* is very large, with longer legs, shorter tail, dark red-brown above with heavy black scaling rather than streaks, dark buff below with large black drop-shaped breast streaks extending to flanks; *nyikae* closely resembles previous, possibly not quite so dark and less extensively marked below; *isolata* is greyish above, tawny below; *tropicalis* is distinctive, has rich orange-red upperparts well streaked blackish, rufous-orange underparts; *ruwenzoria* is greyer and more heavily streaked above than previous; *athi* has grey to buff-grey upperparts streaked blackish, variable, greyest in SE, browner in W, crown rufous in SW; *harterti* resembles previous, but upperpart feathers edged deep orange; *sharpii* is bright rufous-chestnut above with buff-edged feathers, creamy below with chestnut breast streaks; *kurrae* has upperparts vinaceous rufous with heavy black streaking, throat and underparts deep tawny; *stresemanni* is small and dark, has crown and upperparts rich rufous, only very few black streaks, deep cinnamon below; *bamendae* differs from last in heavier streaking above, smaller size; *batesi* is more sandy-coloured and heavily streaked above; *henrici* is also small, very dark and well streaked blackish above, with unmarked crown, belly buffish. Voice. Male (of most races) has short (0·5-0·7 seconds), simple song, "tlee tleeou", "tud tiddle-ooo" or "too too too too", repeated every 2-20 seconds, typically switches call type after 20 or more repetitions, repertoire size not known; song often immediately preceded by wing-rattling; occasionally more complex song, which may include mimicry of other species (but this is rare, compared with *M. hypermetra*), during short aerial display. Peculiarly, in an area of Kenya with few of present species, one or more individuals substituted song of Abyssinian Nightjar (*Caprimulgus poliocephalus*) for the usual one, presumably because the young inadvertently learned incorrect song during their sensitive period. Alarm call "tlew-it" or "twee ki-ree", often given when intruders approach nest.
Habitat. Wide range of grassy habitats from sea-level to 3000 m, including savanna and open woodland, grassland, grassy fynbos, fallow lands and bare areas adjacent to fields. Avoids very dense grassland, preferring areas where at least some bare patches present. In C Africa, prefers dry plains where *M. angolensis* is absent.
Food and Feeding. Insects, including grasshoppers (Acrididae), caterpillars, beetles (Coleoptera), termites (Isoptera), mantids, dipteran larvae, also other invertebrates, including spiders, millipedes (Diplopoda) and earthworms (Oligochaeta); also grass seeds. Forages primarily on the ground, gleaning insects from vegetation or from ground surface; sometimes scratches the earth with its feet or bill. Also searches for food among dung, or in areas where large mammals concentrate. Stands on termite mounds, eating all termites that emerge. Occasionally hawks termite alates but, owing to its laboured flight, seldom successfully.
Breeding. Season mostly Nov-Feb and Apr-Aug; mainly Oct-Feb in S Africa. Monogamous and territorial. Male sings primarily during early breeding season, from low perch, with head thrown backwards 30°-40°; immediately prior to uttering song, often rattles wings, sometimes while jumping a few centimetres into air (this appears to be precursor to wing-clapping display in *M. rufocinnamomea*, *M. apiata*, *M. fasciolata* and *M. collaris*); race *malbranti* has very distinctive display, rising vertically from ground to c. 10 m, where rattles wings and gives 3-note whistle before parachuting back to earth with wings raised and legs outstretched (similar to one of the displays of *M. angolensis*). Nest in shallow scrape, usually at base of a grass tuft or between two tufts, occasionally at base of small bush, lined with grass and other vegetation, this usually woven into overhanging vegetation to form domed roof, thickness of lining and roof varies greatly; in nests with complete roof, access is via a side entrance. Clutch 2-3 eggs, rarely 4 (mean 2·4); incubation apparently only by female, which, when disturbed, is reluctant to return to nest until male signals that it is safe, by calling (often during brief vertical flight); incubation period unknown; chicks brooded by female, but fed by both parents, female bringing more food than male; when disturbed at nest, parents usually creep away mouse-like through grass; chicks leave nest 10-12 days after hatching, before able to fly.
Movements. Resident. Pairs remain on territories and males sing throughout year.
Status and Conservation. Not globally threatened. Generally common; widespread in S, becoming more patchy and localized farther N. Commonest and most widespread lark in E Africa; highly fragmented distribution in W Africa, where local and uncommon to common. Has undoubtedly suffered habitat loss caused by crop-farming; on the other hand, may have benefited from ranching, which tends to reduce grass cover, making rangelands more suitable for this species.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Aspinwall (1979a), Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Byaruhanga *et al.* (2001), Chapin (1953), Clancey (1956a, 1958a, 1964b), Dean (2000), Dowsett (1972b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1978), Elgood *et al.* (1994), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Horne & Short (1998), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1962, 1970), Maclean (1993a), Penry (1994), Short *et al.* (1990), van Someren (1956), Stevenson & Fanshawe (2002), Tarboton (2001), Took (1961), Vernon (1973), White (1956, 1960a), Zimmerman *et al.* (1996).

20. Angola Lark

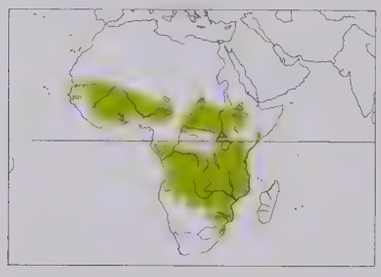
Mirafra angolensis

French: Alouette d'Angola **German**: Angolalerche **Spanish**: Alondra Angoleña
Other common names: Angola Bushlark

Taxonomy. *Mirafra angolensis* Bocage, 1880, Caconda, Benguela, Angola.
Bears close resemblance to *M. africana*, but probably most closely related to the "*M. apiata* complex". Races poorly differentiated; further research may lead to one or more being subsumed. Racial affiliation of birds recently observed in SW Tanzania uncertain, tentatively placed in *marungensis*. Described race *minyanyae* (from NW Zambia) synonymized with *antonii*; birds from S part of Angola (Cuando Cubango) described as race *niethammeri*, but possibly referable to *M. fasciolata*. Three subspecies recognized.
Subspecies and Distribution.
M. a. angolensis Bocage, 1880 - W & C Angola.
M. a. antonii B. P. Hall, 1958 - E Angola, S DRCongo and NW Zambia.
M. a. marungensis B. P. Hall, 1958 - SE DRCongo (Marungu Plateau) and SW Tanzania (near Mumba).

Descriptive notes. 16-17 cm; male 35-42 g, female 30-37 g. Medium-sized, rather dark lark with fairly long, heavy bill. Has buffish lores and indistinct supercilium, dark-streaked brown-buff ear-coverts and neck; crown and upperparts dark reddish-brown, back and wing-coverts with solid blackish-brown centres (not barred or chevroned as in *M. rufocinnamomea*), tertials strongly barred, recalling *M. apiata*. flight-feathers dark brown, edged rufous; tail dark brown, outer rectrices white; underparts buff, with deeper pinkish-buff breast and flanks, breast with well-defined thin streaks; eyes brown; bill dark horn, paler base of lower mandible; legs flesh-brown. Distinguished from *M. rufocinnamomea* by larger size, longer bill, back and wing-coverts with solid dark centres (not barred or chevroned), paler underparts with narrower and more clearly defined breast streaks. Sexes alike. Juvenile has pale-edged feathers above, breast streaks more diffuse and rounded. Races differ in plumage tone, darker and greyer in C of range, more rufous in W & E; *antonii* is darker and greyer than nominate, heavier streaks below; *marungensis* is richer rufous above, more rufous with stronger streaks below. Voice. Male song a series of distinctive, buzzing trills, characteristically varying in pitch, "zi-zi-zi-zi-zi-zu-zu-zu-zu-zi-zi-zi-zi-zi-zu-zu-zu-zu-zu", lasting c. 5 seconds, typically given in aerial display, some-

On following pages: 21. Flappet Lark (*Mirafra rufocinnamomea*); 22. Cape Clapper Lark (*Mirafra apiata*); 23. Eastern Clapper Lark (*Mirafra fasciolata*); 24. Collared Lark (*Mirafra collaris*); 25. Gillett's Lark (*Mirafra gilletti*); 26. Degodi Lark (*Mirafra degodiensis*).



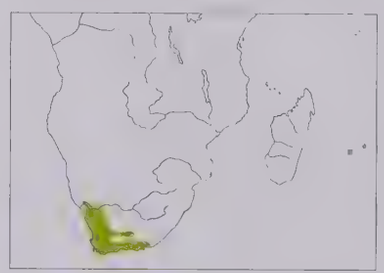
times from ground; also calls "trrp trrp t'tiiiiii tuu" from a termite (Isoptera) mound, followed by ascent with wing-rattling.
Habitat. Montane grassland, usually in damp valleys, in much of range (W Angola, SE DRCongo, SW Tanzania). In C parts (race *antonii*) occurs in dambos and on extensive grassy plains, usually in fairly damp areas, but also in drier sites where *M. africana* is absent. In Zambia, nested in area of short, recently burnt grassland adjacent to a seasonal floodplain on black-cotton soils in area with abundant small termite mounds. Appears to avoid areas where *M. africana* occurs.
Food and Feeding. Insects, including beetles (Coleoptera) and grasshoppers (Acrididae), and seeds. Feeds on ground.
Breeding. Little known. Nest found in Oct; display observed mostly in Jul-Oct, but birds with enlarged gonads in Sept-Jan. Male has short aerial display, rising steeply 25 m into air while singing, then parachuting back to earth; also calls from termite mound, then rises steeply c. 5 m into air, briefly rattling wings at apex of flight. Only one nest found, in shallow depression in ground, thickly lined with grass and rootlets, thinly domed with grass stems woven into the sheltering grass tuft, nest rim decorated with "chopped" rootlets; contained 3 eggs, incubated by female. No other information on parental duties or incubation and fledging periods.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Poorly known species, locally common but apparently rather patchily distributed. Some of its habitat may have been lost to agriculture, but most of its range remains little affected by human activities. Only recently observed in SW Tanzania; no specimens obtained, and further work required in order to determine racial identity of birds involved.
Bibliography. Aspinwall (1979a), Benson *et al.* (1971), Colebrook-Robjent (1988), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Mackworth-Praed & Grant (1962, 1970), Moyer & Sikombe (1992), Moyer & Stjernstedt (1986), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), White (1956).

21. Flappet Lark

Mirafra rufocinnamomea

French: Alouette bourdonnante **Spanish**: Alondra Aplaudidora Canela
German: Baumklapperlerche
Other common names: Cinnamon Bushlark; Buckley's Lark (*buckleyi*)

Taxonomy. *Megalophonus rufo-cinnamomeus* Salvadori, 1865, north Ethiopia.
Closely related to the "*M. apiata* complex", although it overlaps with *M. fasciolata* in N Namibia and N Botswana. Differences among many contiguous races broadly clinal; further study may reveal that several taxa are untenable. Birds from S Tanzania S to C Mozambique named as race *zombae*, but indistinguishable from *fischeri*. Fifteen subspecies recognized.
Subspecies and Distribution.
M. r. buckleyi (Shelley, 1873) - S Mauritania and Senegal E to N Cameroon.
M. r. serlei C. M. N. White, 1960 - SE Nigeria.
M. r. tigrina Oustalet, 1892 - E Cameroon, S Central African Republic and N DRCongo.
M. r. furensis Lynes, 1923 - WC Sudan.
M. r. sobatensis Lynes, 1914 - C Sudan.
M. r. rufocinnamomea (Salvadori, 1865) - N & C Ethiopia.
M. r. omoensis Neumann, 1928 - SW Ethiopia.
M. r. torrida Shelley, 1882 - SE Sudan and S Ethiopia S to N Uganda, C Kenya and N & C Tanzania.
M. r. kawirondensis van Someren, 1921 - E DRCongo, S Uganda and W Kenya.
M. r. schoutedeni C. M. N. White, 1956 - SW Central African Republic, and Gabon E to W DRCongo and S to NW Angola.
M. r. fischeri (Reichenow, 1878) - Angola (except NW) and S DRCongo E to E & S Tanzania, E Kenya and S Somalia, S to N Zambia, Malawi and N Mozambique.
M. r. lwenarum C. M. N. White, 1945 - NW Zambia (Balovale).
M. r. mababiensis (Roberts, 1932) - SE Angola, W Zambia, N Namibia and N Botswana.
M. r. smithersi C. M. N. White, 1956 - SW Zambia, NE Botswana, Zimbabwe and N South Africa.
M. r. pintoi C. M. N. White, 1956 - S Mozambique, NE South Africa and Swaziland.



Descriptive notes. 14-15 cm; 21-32 g. Fairly small, dark lark with indistinct buff supercilium, distinctive wing-clapping display-flight. Nominate race is rufous-red above, heavily patterned with black; flight-feathers with rufous edges; outer rectrices and outer webs of adjacent pair buffy rufous; white throat, rest of underparts rufous, darker and dark-spotted on breast; eyes dark brown; bill dark horny grey above, with much paler and pinker lower mandible; legs flesh-pink. Distinguished from *M. africana* mainly by much smaller size. Sexes alike, female on average slightly smaller. Juvenile has more barred upperparts with feathers pale-tipped. Races vary markedly in plumage coloration, notably ground colour and extent of dark streaking of upperparts, and intensity of colour of underparts: *buckleyi* is dull rufous to cinnamon-brown with black streaks above, creamy buff to orange-buff below; *serlei* is deeper red above and below than last; *tigrina* is less reddish above, heavily marked with black; *furensis* has yellowish-tinged upperparts with reduced black; *sobatensis* is blackish with light buff edgings above, looks scaly; *omoensis* resembles nominate but with heavier black markings above; *torrida* is darker than previous; *kawirondensis* has blackish upperparts with grey-brown edgings; *fischeri* is dark red-brown above, variably patterned with black; *schoutedeni* is paler and browner, and less marked; *lwenarum* is rather pale, pinkish-tinged; *mababiensis* is greyish above; *smithersi* has rather pale brick-red upperparts only lightly marked; *pintoi* is dark with extensive blackish markings above, darker below, especially breast. Voice. Normal song almost entirely replaced by wing-clapping aerial display; occasionally utters thin, wispy song of 4-6 notes during display-flight, or calls "tueee tuee" from ground or low bush.
Habitat. Open woodland, savanna, scrubland, and grassy dambos in closed-canopy woodland, usually in mesic areas. Density typically greater in lightly wooded habitats than in open ones.
Food and Feeding. Mostly insects, including termites (Isoptera), caterpillars, beetles (Coleoptera), grasshoppers (Acrididae) and mantids; also a few grass seeds. In examination of contents of nine stomachs from DRCongo, only one contained seeds. Forages on the ground, seldom digging for food.
Breeding. Season May-Oct in W Africa, May-Aug and Nov-Dec in E Africa, and Sept-Mar in C & S Africa. Apparently monogamous. Male displays sporadically throughout year, mostly during breeding season, circles high over territory, produces usually 2-3 bursts of rapid, machine-gun-like clapping by hitting wings together beneath body (causing bird to rise 1-2 m), repeated every 3-10 seconds; wingbeat frequency more than doubles, from 10-11 Hz to 24 Hz, during clapping; structure of each "song" shares many of characteristics of vocal displays, including individual variation and regional "dialects" which are constant between years. Nest built in shallow scrape at base of a grass tuft or bush, often in rocky area, lined with grass and rootlets, usually domed and with side entrance, sometimes only a partial roof, at other times quite exposed and with little roof at all. Clutch 2-3 eggs, rarely 4 (mean 2·2); incubation period unknown; at one nest found just before hatching, male hovered nearby, wing-clapping in brief bursts, until intruder left, whereupon female crept cautiously back to nest; chicks leave nest 11 days after hatching, before able to fly.
Movements. Resident. Pairs remain on territories throughout year.
Status and Conservation. Not globally threatened. Locally common throughout much of its wide range. Suitable habitat has undoubtedly been lost to agriculture, because the species avoids fields and pastures; nevertheless, large numbers are protected in the many large savanna reserves in its range. Numbers were found to be higher close to stations baited for control of tsetse fly (*Glossina*) than at other monitored sites nearby, but this probably the result of creation of artificial clearings around the bait stations.
Bibliography. Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Bertram (1977), Borrow & Demey (2001), Byaruhanga *et al.* (2001), Chapin (1953), Cheke & Walsh (1996), Clancey (1964b), De Garine-Wichatitsky *et al.* (2001), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Ginn *et al.* (1989), Grimes (1987), Harrison *et al.* (1997), Irwin (1958), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1962, 1970), Maclean (1993a), Nikolaus (1987), Norberg (1991), Payne (1973, 1978, 1981), Penry (1994), Seibt (1975), Short *et al.* (1990), Sinclair & Hockey (1996), van Someren (1956), Stevenson & Fanshawe (2002), Tarboton (2001), Wickler (1967), Zimmerman *et al.* (1996).

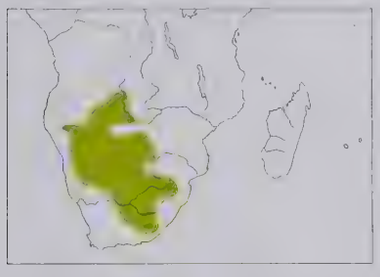
22. Cape Clapper Lark

Mirafra apiata

French: Alouette bateleuse **Spanish**: Alondra Aplaudidora de El Cabo
German: Grasklapperlerche
Other common names: Bar-tailed Lark(!); Agulhas Clapper Lark (*marjoriae*)

Taxonomy. *Alauda apiata* Vieillot, 1816, Swartland = Malmesbury, Western Cape, South Africa.
In the past, has usually been treated as conspecific with *M. fasciolata*; the two were recently resplit on basis of plumage, morphology, display and genetic differences; boundary between the two species in Eastern Cape requires investigation. Race *marjoriae* also genetically distinct, but plumage differences from nominate slight; further study needed. Nominate shows clinal variation in overall coloration, from generally more rufous birds in extreme W South Africa (proposed race *adendorffi*) towards darker birds in S, but these extremes virtually matched by notable individual variation at any one site. Proposed race *algoensis* (Port Elizabeth area) very similar to nominate, and not reliably separable, especially in view of marked individual variation within nominate. Two subspecies recognized
Subspecies and Distribution.
M. a. apiata (Vieillot, 1816) - SW Namibia and W coastal plain and interior of South Africa (Northern Cape and Western Cape E to Grahamstown).
M. a. marjoriae Winterbottom, 1956 - coastal plain of Western Cape (from Cape Town E to Knysna).

Descriptive notes. 12-14 cm; 23-33 g. Fairly small, compact lark with plain face, rather dark plumage, distinctive fast wing-clapping display. Is heavily mottled chestnut, dark brown and grey above, individual feathers on crown, back, wing-coverts and tertials barred dark brown and rich chestnut, variable, in NW (Namaqualand) on average more chestnut above and sometimes having almost uniform chestnut crown ("*adendorffi*"); flight-feathers mostly dark brown, edge of outer webs rufous; outer tail feather edged buffy white, this extending variably on to inner web; throat whitish, rest of underparts rich buffy, breast variably spotted with dark brown, spots usually extending on to throat; eyes brown; bill dark greyhorn, with paler base to lower mandible; legs flesh-brown. Distinguished from *M. fasciolata* by slightly smaller size, darker and less rufous appearance, less rufous on flight-feathers, also faster display-clapping. Sexes alike. Juvenile has pale-tipped upperpart feathers. Race *marjoriae* is darker than nominate, with broader dark brown bars and narrower chestnut bars on upperpart feathers. Voice. True song replaced by aerial wing-clapping display, accompanied by a simple, ascending whistle, "phoooeeee" (most populations); *marjoriae* gives two descending whistles, "tseeoo tseeuuu", which commence earlier in display, could be confused with song of *Certhilauda brevirostris*. Occasionally mimics other species, but much less frequently than does *M. fasciolata*. Singing occurs mostly in morning and evening, but often continues after dark, especially on moonlit nights.
Habitat. Prefers densely vegetated habitats; favours areas with restios such as sand-plain fynbos and arid mountain fynbos, but also Renosterveld shrubland and Karoo scrub. Also occurs in fallow fields, and occasionally in dense cereal crops, where these abut natural vegetation. Generally avoids strandveld vegetation along coast.
Food and Feeding. Little known. Probably mostly insects and some seeds. Feeds on the ground. Rather unobtrusive; if approached, prefers to creep away rather than to fly.
Breeding. Aug-Oct. Probably monogamous; territorial. Display tends to be strongly seasonal, linked to breeding activity; displaying male moves slowly around territory, or makes circuits during flights, rises steeply from ground or low perch, clapping wings together beneath body, rate of clapping rises from initial 12-14 beats per second to more than 25 per second at peak of ascent, whereupon it whistles and parachutes to ground; usually 10-15 seconds between displays, but sometimes multiple displays in same flight, with bird undertaking extended display-flights similar to those of *M. rufocinnamomea*; maximum clap rate varies less than other display characteristics, and very little variation among fastest-clapping males, suggesting that direct selection for fast clapping exists. Nest in shallow depression in ground, usually at base of a plant, cup lined with grass, rootlets and other vegetation, this usually extending over top to form a domed roof, or sometimes completely enclosing nest to leave only a single side entrance. Clutch 2-3 eggs; no information on parental duties or incubation and fledging periods.
Movements. Resident. Atlas survey records strongly seasonal, but this reflects seasonal differences in species' detectability.
Status and Conservation. Not globally threatened. Common in many parts of range. Present in Etosha National Park, Namibia. Despite extensive habitat loss to agriculture in coastal lowlands of



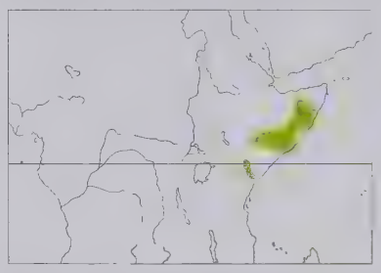
Western Cape, it remains reasonably common in many areas. Its range has contracted significantly on the flats near Cape Town as a result of urban expansion, leading to increasing isolation of the very small population in Cape Point sector of the Cape Peninsula National Park.
Bibliography. Cardwell & Dunning (1971), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Hester (2000), Keith *et al.* (1992), Macdonald (1952a), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Maclean (1993a), Quickelberge (1970a), Ryan & Marshall (1998), Sinclair & Hockey (1996), Tarboton (2001), Vincent (1946).

23. Eastern Clapper Lark

Mirafra fasciolata

French: Alouette fasciée **German**: Ostklapperlerche **Spanish**: Alondra Aplaudidora Oriental
Other common names: Damara Clapper Lark ("*damarensis*"); Namaqua Clapper Lark (*fasciolata*)

Taxonomy. *Alauda fasciolata* Sundevall, 1850, Vaal River, Transvaal, South Africa.
Scientific name for species formerly given as *rufipilea*, but that name is apparently indeterminate. In the past, was usually treated as conspecific with *M. apiata*; the two were recently resplit on basis of plumage, morphology, display and genetic differences; boundary between the two species in Eastern Cape (South Africa) requires investigation. Geographical differences broadly clinal; further study may lead to several races being subsumed, especially in N of range (where only small series of specimens obtained); *damarensis* possibly an intergrade between *deserti* and *reynoldsi*. Name *hewitti* is a junior synonym of nominate. Birds from W Botswana (Ngamiland and Kalahari) described as race *kalaharica*, but not consistently different from *deserti*. Five subspecies currently recognized.
Subspecies and Distribution.
M. f. reynoldsi Benson & Irwin, 1965 - SW Zambia, N Namibia and N Botswana; probably also SE Angola.
M. f. jappi Traylor, 1962 - W Zambia.
M. f. nata Smithers, 1955 - NE Botswana.
M. f. deserti (Roberts, 1926) - EC Namibia and W, E & S Botswana.
M. f. fasciolata (Sundevall, 1850) - C & E South Africa.



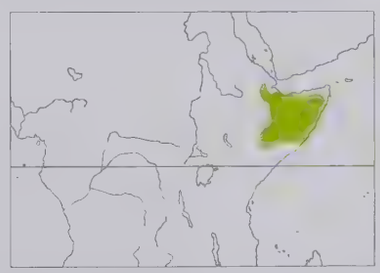
Descriptive notes. 13-15 cm; 26-44 g. Medium-sized, compact lark with a fairly short, stout bill, indistinct weak supercilium, and distinctive wing-clapping display. Nominate race has crown and upperparts rich rufous, upperparts finely barred dark and, in fresh plumage, with white tips of feathers; broad rufous bases of primaries (forming distinct rufous patch in flight); outer tail feather edged buffy white, this colour extending variably on to inner web; throat whitish, rest of underparts rufous-buff, with some indistinct brown spotting on breast; eyes brown; bill dark grey-horn; legs flesh-brown. Distinguished from *M. apiata* by larger size (on average c. 10% bigger), heavier and paler bill, plainer and more rufous plumage, less extensive spotting below, also slower wing-clapping in display; from *M. rufocinnamomea* by appreciably larger size, paler plumage, heavier bill; from *M. africana* mainly by smaller size, shorter bill, plain or finely barred upperparts lacking strong dark streaks. Sexes alike in plumage. Juvenile has pale-tipped upperpart feathers. Races vary markedly in plumage colour, upperparts becoming paler and greyer and underparts whitish in N: *deserti* is larger and paler than nominate; *reynoldsi* is ash-grey with variable pale sandy tinge above, typically pale creamy with irregular buff-brown tinge below, underparts sometimes darker brown; *nata* resembles previous, but mantle paler, greyish to light sandy-brown, crown usually reddish (variable); *jappi* is darker with browner barring above, browner below. Voice. Displaying male gives ascending whistle, "phooeeee", similar to that of *M. apiata* but with less change in pitch, also extra notes frequently added, e.g. "phooeeee weeter-eeter-eerrr"; mimics other birds more often than does *M. apiata*.
Habitat. Tall grassland, often in rocky areas, in S; sparse, semi-arid grasslands in Kalahari Desert; grassy margins of pans and plains farther N. Generally avoids croplands, but occurs in lightly grazed rangelands.
Food and Feeding. Insects, including termites (Isoptera) and ants, also other invertebrates; also seeds. Forages on ground. Occasionally follows aardvarks (*Orycteropus afer*), searching their diggings for termites.
Breeding. Season Sept-Feb. Monogamous and territorial. Displaying male rises steeply from ground and claps wings beneath body, uttering whistle at peak of ascent, before parachuting back to ground, or, more often, conducts extended flights with repeated clapping for up to 10 minutes; unlike *M. apiata*, no acceleration in wing-clap rate during display. Nest built in shallow depression in ground, at base of a grass tuft, between two tufts or next to a rock, lined with grass or other vegetation, with domed roof sometimes completely enclosing nest apart from side entrance hole; thickness of lining and of roof varies, from thin and flimsy to quite substantial. Clutch 2-3 eggs; no information on parental duties and duration of incubation period; when nest approached, parents perform distraction display by flying low in front of intruder and snapping the wings; chicks leave nest 11 days after hatching, before able to fly.
Movements. Probably resident, but subject to local movements in areas where habitat flooded seasonally and, perhaps, in more arid areas. Atlas-survey records show peak in reporting rate in Sept-Jan, coinciding with peak in breeding activity.
Status and Conservation. Not globally threatened. Locally common and widespread in S of range; patchily distributed in N; is easily overlooked when not displaying. Although it has suffered habitat loss through development for agriculture, especially in S of its range, it is still common in many parts. Large numbers are conserved in formally protected areas.
Bibliography. Benson *et al.* (1971), Harrison *et al.* (1997), Hester (2000), Irwin (1958), Keith *et al.* (1992), Macdonald (1952a), Penry (1994), Quickelberge (1970a), Sinclair & Ryan (2003), Vernon (1973), Vernon & Dean (1988).

24. Collared Lark

Mirafra collaris

French: Alouette à collier **German**: Halsbandlerche **Spanish**: Alondra Acollarada
Other common names: Collared Bushlark

Taxonomy. *Mirafra collaris* Sharpe, 1896, Aimola, north-east Kenya.
Affinities to *M. apiata* and *M. fasciolata* suggested by clapping display-flight, although wing-clapping performed also by unrelated *Chersophilus duponti*. Preliminary genetic data suggest affinities with *Calendulauda*. Monotypic.
Distribution. SE Ethiopia, Somalia and NE & E Kenya.



Descriptive notes. 13-15 cm. Plain rufous lark with distinctive black breastband. Has face quite well marked, with prominent whitish supercilium; crown and ear-coverts rufous, nape and neck side whitish with black streaks, forming distinct hindcollar; upperparts rufous, fine white streaks formed by pale edges of inner feather margins, wing-coverts edged paler buff in fresh plumage; blackish flight-feathers and tail (distinctive in flight), primaries tipped and edged white; throat white, sharply defined black band on upper breast, contrasting also with rufous-streaked lower breast, rest of underparts paler; eyes brown; bill dark brown above, whitish below; legs pale pink-brown. Distinguished from superficially similar *Calendulauda alopex* by collar, breastband and blackish flight-feathers. Sexes alike. Juvenile lacks distinctive collar, has pale-fringed upperpart feathers with dark subterminal bands (scaly appearance), buffy breast with blackish-brown spots, white belly. Voice. Male song a plaintive, ascending whistle that increases in volume, then fades away, usually uttered from perch after wing-clapping display-flight, sometimes also while descending from display.
Habitat. Semi-arid savanna, grassland with scattered shrubs, and open acacia (*Acacia*) and *Commiphora* woodland. Invariably found on red sands.
Food and Feeding. Grasshoppers (Acrididae), caterpillars, other insects, also seeds. Feeds on ground; reluctant to fly, runs off rapidly if pursued.
Breeding. Nests with eggs found in May in Ethiopia and Somalia; displays in Oct in Kenya. Probably monogamous. Displaying male rises steeply from ground, clapping wings beneath body, to height of 10-15 m, and then glides or slow-flaps gently downwards, sometimes changing direction once or twice as it drops, usually lands on top of bush or small tree or, more rarely, on ground, and calls. Nest built in shallow scrape at base of a grass tuft, cup lined with dry grass, and grass built over top to form domed roof. Clutch 2-3 eggs (mean 2·7); no information on parental duties or incubation and fledging periods.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Locally common. Density of 1-2 displaying males/ha recorded after rain. No clear threats known.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Bennun & Njoroge (1999), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Short *et al.* (1990), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

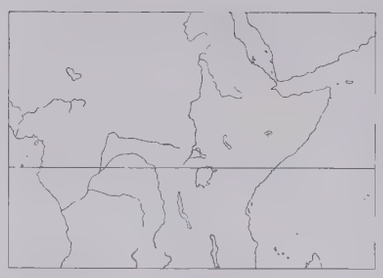
25. Gillett's Lark

Mirafra gilletti

French: Alouette de Gillett **German**: Gillettlerche **Spanish**: Alondra de Gillett

Taxonomy. *Mirafra gilletti* Sharpe, 1895, Sibbe, Ogaden country, north-west Somalia.
Widely regarded as forming a superspecies with *M. degodiensis*; the two occur within 50 km of each other with no known overlap in ranges, although region is poorly known ornithologically. Has also been suggested to form a superspecies with *M. rufa* and the taxon *poecilosterna*, although genetic evidence indicates that latter better placed in genus *Calendulauda*; also bears close resemblance to *C. alopex* of race *intercedens*, and thus possibly better shifted to that genus; no genetic data yet available for present species or *M. rufa*. Race *arorihensis* intergrades with nominate in NW Somalia. Two subspecies recognized.
Subspecies and Distribution.
M. g. gilletti Sharpe, 1895 - E Ethiopia, W Somalia and extreme NE Kenya.
M. g. arorihensis Érard, 1975 - Somalia.

Descriptive notes. 16-17 cm; 20-26 g. Medium-sized lark with rufous-brown upperparts, broad whitish supercilium and well-marked face. Plumage is largely rufous-brown above; upperparts variably streaked dark brown, rump and uppertail-coverts a greyer brown and contrasting somewhat with more rufous back; greater and median wing-coverts dark brown, broadly fringed rufous-brown; flight-feathers brown with narrow buff edges, tertials broadly edged rufous-brown; tail brown, central feathers broadly edged rufous; whitish below, breast with rufous streaks, sometimes darker brown centrally; eyes light brown; bill dark brown above, paler below; legs pale brown. Distinguished from *M. degodiensis* by darker and more rufous upperparts, stronger breast markings; from similar *Calendulauda alopex* (of race *intercedens*) by slightly larger size, less streaking above, no contrast between back and rump, buff (not rufous) edges of flight-feathers, paler breast streaks, different habitat. Sexes alike. Juvenile unknown. Race *arorihensis* is paler and more rufous above than nominate. Voice. Little known; reported as calling "dsee-dsit" from elevated perch, usually top of small tree or bush; also gives longer song in aerial display.
Habitat. Semi-arid savanna and scrub, typically on hard substrates, often near rocky areas; absent from soft, sandy soils to which *Calendulauda alopex* is confined. In Somalia, avoids areas with annual rainfall less than 75 mm or more than 450 mm, being replaced in more mesic areas in S by *Calendulauda poecilosterna*. Occurs from near sea-level to 1500 m.
Food and Feeding. Beetles (Coleoptera), caterpillars, grasshoppers (Acrididae) and seeds. Feeds on ground.
Breeding. Breeds Apr-Jun in Somalia. Monogamous; occurs singly or in pairs throughout year. Displaying male flies up to 100 m above ground for several minutes, singing continuously, then plummets vertically back to earth. Nest a shallow scrape at base of a grass tuft or shrub, lined with a cup of fine grass stems and rootlets. Clutch 3 eggs; nothing known about parental duties or incubation and fledging periods.
Movements. Apparently resident.



Status and Conservation. Not globally threatened. Fairly common, but thinly distributed and nowhere abundant. Present in Awash National Park, Ethiopia. No obvious threats.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Bennun & Njoroge (1999), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Érard (1975a), von Erlanger (1907), Fishpool & Evans (2001), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Miskell & Ash (1985), Shirihai & Francis (1999), Short *et al.* (1990), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

26. Degodi Lark

Mirafra degodiensis

French: Alouette du Degodi **German**: Degodilerche **Spanish**: Alondra de Degodi
Other common names: Erard's Lark

Taxonomy. *Mirafra degodiensis* Érard, 1975, Bogo-Mayo, Degodi, Sidamo Province, south Ethiopia. Possibly better placed in genus *Calendulauda*. Usually considered to form a superspecies with *M. gilletti*; the two occur within 50 km of each other with no known overlap in ranges, although region is poorly known ornithologically. Monotypic.
Distribution. Near Bogol Manya, in Degodi region of S Ethiopia.
Descriptive notes. 16 cm. Medium-sized lark, finely but densely streaked above, resembling a pipit (*Anthus*). Has whitish supercilium contrasting with dark brown eyestripe and pale rufous-washed ear-coverts; dull brown above, crown washed rufous to sandy, slightly paler and greyish-brown on nape; wing-coverts have broad buffy margins, especially median coverts (which appear as a row of blackish spots above a pale wingbar); flight-feathers dark brown with narrow buff margins; underparts white or creamy white, breast with rufous-brown streaks; eyes dark brown; bill pale horn, darker and greyer above; legs pinkish to brownish. Distinguished from *M. gilletti* by slightly smaller size, paler and less rufous upperparts, less heavily streaked breast; from *Calendulauda alopex* mainly by lack of rufous wingpanel; from structurally similar *Calendulauda poecilosterna* by more patterned upperparts, less mottled breast. Sexes alike. Juvenile unknown.

Voice. Calls "tsee tsee" from top of small bush; playback of this elicited short, lower-pitched song, "twill-ill-ill-ill-ill-it". Also reported as uttering repeated sibilant trill, similar to that of *C. poecilosterna*, with occasional notes similar to those of *M. gilletti*.
Habitat. Arid acacia (*Acacia*) scrub with little ground cover, at 300-400 m elevation.
Food and Feeding. Grasshoppers (Acrididae) and small caterpillars. Feeds on ground, typically remaining in shade of bushes during most of day. Occurs singly or in pairs.
Breeding. No information; nest and eggs undescribed.
Movements. Apparently resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Jubba and Shabeelle Valleys EBA. Known from only a very small area of S Ethiopia, having estimated total range of 430 km^2. Global population estimate of fewer than 1000 individuals, but this extremely tenuous; may well be more common. No recent systematic searches of the general region, which is troubled by banditry. Status poorly known; concerns about possible habitat loss and degradation through grazing and firewood-collecting resulted in its being listed as globally threatened, although possibly more accurately categorized as Data-deficient. As there are no protected areas within its range, however, a precautionary approach is warranted. Conservation targets include fieldwork aimed at accurately assessing the species' current range and abundance, and identifying threats to its habitat.
Bibliography. Ash & Gullick (1990), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Érard (1975a), Fishpool & Evans (2001), Hockey (1997a), Keith *et al.* (1992), Shirihai & Francis (1999), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Webb & Smith (1996).

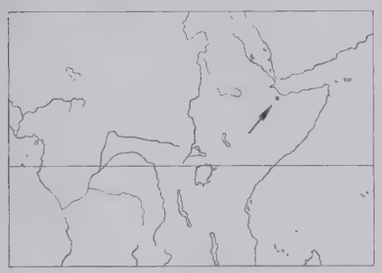
Genus *HETEROMIRAFRA*



C. H. B. Grant, 1913

27. Archer's Lark

Heteromirafra archeri

French: Alouette d'Archer **German**: Somalispornlerche **Spanish**: Alondra de Archer
Other common names: Archer's Long-clawed Lark, Somali (Long-clawed) Lark

Taxonomy. *Heteromirafra archeri* S. R. Clarke, 1920, Jifa, 5000 feet [c. 1500 m], Somalia.
Forms a superspecies with *H. sidamoensis* and *H. ruddi*. Monotypic.
Distribution. NW Somalia.

Descriptive notes. 15-16 cm. Peculiar short-tailed, large-headed lark with extremely long hind claw. Has pale median crownstripe, broad creamy supercilium; boldly patterned above, with rufous and dark brown feathers broadly edged buff and whitish on crown and back, paler neck and mantle buffy brown with dark streaks; wing-coverts and tertials broadly edged creamy buff; flight-feathers dark brown with narrow buff edges; tail dark brown with cream-buff margins, outer feather entirely creamy buff; underparts creamy buff, with fine dark brown streaks on breast; eyes brown; bill pale horn-brown above, whitish-horn below; legs pale flesh-brown. Distinguished from *H. ruddi* by slightly larger size, paler upperparts (broader pale feather margins), better-defined spots on breast; from *H. sidamoensis* by slightly smaller size and paler plumage, with creamy (rather than warm rufous-buff) feather edges; from *Mirafra cantillans* by larger size, much shorter tail, rufous in wing. Sexes alike. Juvenile unknown. VOICE. Unknown.
Habitat. Open grassland at one site (between Jifa and Ban Wujaleh); at other, 100 km to NW (N of Buramo), more rocky terrain with sparse shrubland and scattered grass. Both sites at 1500 m elevation, with annual rainfall 300-400 mm.
Food and Feeding. Diet unknown. Extremely secretive; when disturbed, creeps through grass in manner of a rail (Rallidae) and scuttles across open patches.
Breeding. Little known. Breeds in Jun. Probably monogamous. Display not known. Nest built from fibrous brown grass woven deep into base of a sheltering grass tuft; described as funnel-shaped, presumably an elongate, completely domed cup like that of *H. ruddi*. Clutch 3 eggs; nothing known about parental duties or incubation and fledging periods.
Movements. Probably resident.
Status and Conservation. VULNERABLE. Extremely small range; known from only two small areas in NW Somalia. Originally discovered in 200 km² of open grassland between Jifa and Ban Wujaleh; later found 100 km NW of there, at locality N of Buramo. Total population estimated at fewer than 1000 individuals, but this figure extremely uncertain. Last seen in 1955; more recent surveys in 1970s and 1990s failed to locate it at either site, or in similar habitat in adjacent areas of Ethiopia; recent claims that it had been discovered on Ethiopia-Somalia border subsequently retracted. Possibly more widespread than the few records suggest, as it is easily overlooked. There are no protected areas within its range, and the grassland site near Jifa has been settled by refugees. Main conservation targets are to relocate this species and accurately to assess its range and abundance, as well as likely threats to its survival.
Bibliography. Anon. (1996d), Archer & Godman (1937-1961), Ash & Miskell (1998), Clarke (1920), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Mackworth-Praed & Grant (1960), Sinclair & Ryan (2003), Stattersfield & Capper (2000).

28. Sidamo Lark

Heteromirafra sidamoensis

French: Alouette d'Érard **German**: Sidamospornlerche **Spanish**: Alondra de Sidamo
Other common names: Sidamo Bushlark, Ethiopian Long-clawed/Sidamo Long-clawed Lark

Taxonomy. *Mirafra sidamoensis* Érard, 1975, Negelli, Sidamo Province, Ethiopia.
Forms a superspecies with *H. archeri* and *H. ruddi*. Monotypic.
Distribution. Area S of Negele (Sidamo Province), in S Ethiopia.

Descriptive notes. 16-17 cm; 30 g. Peculiar short-tailed, large-headed, lark with long slender neck, extremely long hind claw. Large dark eye contrasts with pale supercilium, relatively plain rufous-brown ear-coverts and buffy lores; pale median crownstripe; feathers of crown, back, wing-coverts and tertials dark rufescent brown, each with blackish centre and subterminal fringe, and prominent buff to white fringe, giving scaly appearance, shafts of wing-coverts and tertials white; nape and mantle pinkish- to greyish-buff with darker streaks, streaks extending from neck down to breast side; flight-feathers dark rufous-brown with pale pinkish-buff outer margins, tail browner, outer rectrix dark pinkish-fawn; whitish below, variable buff wash on breast and flanks; eyes dark brown; bill yellowish-horn; legs and feet straw-brown to pinkish. Differs from *H. archeri* and *H. ruddi* in slightly larger size and more rufous appearance, darker outer tail, at close range white shafts of wing-coverts and tertials; readily distinguished from *Mirafra rufocinnamomea* by general shape, distinctive plumage features, also different display. Sexes alike. Juvenile unknown. VOICE. Male song a series of buzzy whistles and trills, longer and more varied than that of *H. ruddi*, typically given in aerial display; when flushed, sometimes a soft "tswee-ee-eep" while hovering briefly 3-4 m above ground.
Habitat. Open grassland patches with scattered bushes among denser semi-arid acacia (*Acacia*) savanna and woodland, at 1450 m.
Food and Feeding. Diet unknown. Often stands upright, but when disturbed scuttles away, keeping to dense cover, and hard to relocate; behaviour similar to that of congeners.
Breeding. Virtually unknown. Display observed in Jan-May. Sings in protracted aerial display, with several males calling at once while circling over territories. Nest and eggs undescribed.
Movements. Probably resident.
Status and Conservation. VULNERABLE. Restricted-range species; present in South Ethiopian Highlands EBA. Known from only two sites, both rather atypical open areas of short grass in semi-arid acacia savanna. Potential global range estimated as 5400 km² and total population as 2500-10,000 individuals by BirdLife International; basis for this rather large range estimation, however, unclear. No recent systematic surveys; the species was not located during several visits to the area, but is easily overlooked if not calling. No protected areas exist within its range. Conservation targets include accurate mapping of its area of distribution and the identification of any specific threats to its habitat.
Bibliography. 29. Rudd's Lark

Heteromirafra ruddi

French: Alouette de Rudd **German**: Transvaalspornlerche **Spanish**: Alondra de Rudd
Other common names: Rudd's Long-clawed Lark, (South African) Long-clawed Lark

Taxonomy. *Heteronyx ruddi* C. H. B. Grant, 1908, Wakkerstroom, Mpumulanga, South Africa.
Forms a superspecies with *H. archeri* and *H. sidamoensis*. Monotypic.
Distribution. NE & E South Africa; isolated populations in SE Mpumulanga, E Free State, KwaZulu-Natal and Eastern Cape.

Descriptive notes. 14-15 cm; 26-27 g. Peculiar lark with very short thin tail, extremely long hind claw, rather slender bill extending up forehead almost as "shield" (deep, unusually broad base); in erect stance, head appears large on a long, slender neck. Has pale median crownstripe, prominent pale supercilium, darker eyestripe, mottled buff-brown ear-coverts; large, dark eye prominent in otherwise rather plain face; crown and back feathers blackish-brown with buff fringes, contrasting with paler buffy-brown neck and mantle, which only lightly streaked darker; flight-feathers dark brown with rufous edges, tail with narrow white margins of outer feathers; cream below, diffuse brown streaks on buff-washed breast; eyes brown; bill pinkish-horn, slightly darker tip; legs pale pink. Distinguished from *H. archeri* by slightly smaller size, darker-looking upperparts (narrower pale fringes), bigger but more diffuse spots on breast; from *H. sidamoensis* by slightly smaller size, less rufous appearance, paler outer tail. Sexes alike. Juvenile has broader buff margins above, appearing more heavily scaled. VOICE. Male song, usually in aerial display, sporadically also from ground, a buzzy series of 3-8 (mean 6) whistles, trills and clicks, repeated every 5 seconds, each song motif repeated 10-20 times before switching to another motif, sometimes different motifs alternated with only few repeats of each; repertoire size not known but each motif created by reordering or omission of notes. Rapid series of 5-7 "peep" notes, 1 per 0·1 seconds, as alarm, usually near nest.
Habitat. Moist montane grassland, at 1600-2200 m, in areas where annual rainfall predictably exceeds 600 mm. Usually found on ridges and slopes with short, dense grass but relatively low ground cover. Prefers natural grassland that is moderately to heavily grazed; avoids planted pastures and rocky areas.
Food and Feeding. Caterpillars, grasshoppers (Acrididae), beetles (Coleoptera), other insects, also seeds. Feeds on ground, walking quickly for a few paces, then stopping and standing erect to survey area; gait recalls that of *Chersomanes albofasciata*, but perhaps more "leggy", and centre of gravity farther forward. Forages singly, taking most prey from bases of grass tufts, or gleaning from leaves; not known to dig for food. Crouches when threatened, and scurries away through grass.
Breeding. Breeds Nov-Feb. Monogamous; territorial, with adjacent nests at least 100 m apart. Displaying male circles 20-30 m over territory, or hangs motionless by fluttering slowly into wind, for protracted period, up to 40 minutes; before copulating, struts in front of female while holding a beakful of nesting material. Nest built by one of pair (probably female), which collects all material within radius of 10 m of site, in one case material delivered 10 times in 30 minutes; in scrape in ground between two grass tufts, made from old grass stems and leaves, lined with finer material, once including a piece of wool, well constructed, with thick roof and walls forming dome, often a short entrance tube; no regular pattern in nest orientation. Clutch 3 eggs, rarely 2, will re-lay several times following loss of clutch; incubation period not known, although eggs hatch within at least 14 days; chicks fed by both parents, fledging period unknown. Breeding success low, daily nest-failure rate 8-9%; most losses apparently due to predation.
Movements. Resident.
Status and Conservation. CRITICAL. Restricted-range species; present in South African Grasslands EBA. Occurs as several isolated populations limited to grasslands; potential range 22,000 km², but actual range probably much smaller. Global population estimated at 2500-5000 individuals, the

On following pages: 30. Pink-breasted Lark (*Calendulauda poecilosterna*); 31. Sabota Lark (*Calendulauda sabota*); 32. Fawn-coloured Lark (*Calendulauda africanoides*); 33. Foxy Lark (*Calendulauda alopex*); 34. Red Lark (*Calendulauda burra*); 35. Karoo Lark (*Calendulauda albescens*); 36. Barlow's Lark (*Calendulauda barlowi*); 37. Dune Lark (*Calendulauda erythrochlamys*).

vast majority in Mpumulanga, E Free State and N KwaZulu-Natal; small, isolated populations occur near Matatiele (SW KwaZulu-Natal), Ncora Dam and Molteno (Eastern Cape). Even where present, it is very patchily distributed within seemingly suitable habitat; density reaches 1 singing male/ha; becomes hard to locate outside breeding season. This species' population has been severely fragmented by agriculture and afforestation. Most individuals are found on privately owned land; only a few in the Verloren Vlei Nature Reserve. The establishment of a Grassland Biosphere Reserve centred on Wakkerstroom, in Mpumulanga, would encompass a significant number of this species, but progress towards this goal has been slow. Conservation targets include research to facilitate an understanding of reasons for its patchy distribution, and the identification of beneficial land-management practices.

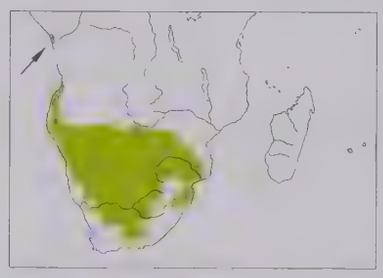
Genus *CALENDULAUDA* Blyth, 1855

30. Pink-breasted Lark

Calendulauda poecilosterna

French: Alouette à poitrine rose **German**: Fahlbrustlerche **Spanish**: Alondra Pechirrosa

Taxonomy. *Alauda poecilosterna* Reichenow, 1879, Kibaradja, Tana River, Kenya.
Formerly placed in genus *Mirafra*, and suggested as forming a superspecies with *M. rufa* and *M. gilletti*; genetic data, however, indicate that it belongs in the *Calendulauda* clade. Geographical variation in plumage tone, darkest and richest in S; birds from extreme N of range (SE Sudan E to S Somalia) described as race *australoabyssinica* and others from rest of range (except N & E Kenya) as *massaica*, but differences minimal, and naming of races considered unwarranted. Monotypic.
Distribution. Extreme SE Sudan and S Ethiopia E to S Somalia, S to NE Uganda, much of Kenya and NE Tanzania.



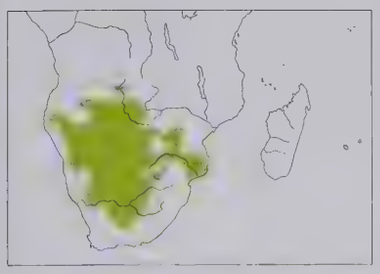
Descriptive notes. 15-16 cm; 23-26 g. Rather peculiar lark with shape like that of a pipit (*Anthus*), having slender bill, long tail, comparatively plain plumage, rather horizontal stance. Plain, pink-washed buffy face and breast are distinctive; relatively plain grey-brown above, with noticeably grey crown; wing-coverts have paler fringes, especially on median coverts, forming indistinct pale wingbar; flight-feathers brown with narrow pale edges, tail brown; pinkish-buff below, breast variably streaked brown, lower underparts white; eyes dull red-brown; bill dark horn with much paler base; legs pale flesh-brown. Sexes alike, female slightly smaller. Juvenile is slightly more rufous below, with more prominent dark spotting on breast. Voice. Song a monotonous, simple series of 6-8 squeaky notes, accelerating and descending in pitch towards end. Also soft "tseet", given sometimes from ground.
Habitat. Arid acacia (*Acacia*) and *Commiphora* savanna and scrub, typically in areas with little ground cover. Prefers sandy soils.
Food and Feeding. Food mostly insects, including large numbers of termites (Isoptera); some seeds. Feeds on ground, mostly by picking items from soil surface.
Breeding. Breeds during rains, laying dates Dec-Jan and Mar-Jun. Monogamous and territorial. Male typically sings from elevated perch, usually top of tall bush or tree; very rarely undertakes display flights. Nest a partially domed cup of dry grass in shallow depression on ground, usually next to a small bush, grass tuft or log. Clutch 2 eggs; no information on parental duties and incubation and fledging periods.
Movements. Resident; remains in pairs and holds territories throughout year.
Status and Conservation. Not globally threatened. Common in most areas. Its range has almost certainly decreased as a result of agriculture, as it avoids open fields and croplands.
Bibliography. Ash & Miskell (1998), Bennun & Njoroge (1999), Byaruhanga *et al.* (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Friedmann (1937), Keith *et al.* (1992), Lack (1976, 1985), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Nikolaus (1987), Short *et al.* (1990), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

31. Sabota Lark

Calendulauda sabota

French: Alouette sabota **German**: Sabotalerche **Spanish**: Alondra Sabota
Other common names: Bradfield's/Large-billed Lark ("*naevia* group")

Taxonomy. *Mirafra Sabota* A. Smith, 1836, "between Latakoo and the Tropic" (= Rustenburg), Northwest Province, South Africa.
Formerly placed in genus *Mirafra*, but genetic data indicate that it belongs with present genus. Large-billed races *naevia*, *herero* and *bradfieldi* sometimes treated together as a separate species; limited genetic evidence supports this split, but further work needed. Geographical variation within both "small-billed group" and "large-billed group" broadly clinal, and further study may reveal that several taxa are not sustainable. Other named races are *elfriedae* (E end of Etosha Pan, in N Namibia), *hoeschi* (N Damaraland, in NC Namibia) and *veseyfitzgeraldi* (NW Botswana), all synonymized with *waibeli*, and Namibian forms *erongo* and *uis* (both from NW Damaraland), considered inseparable from *naevia*. Nine subspecies recognized.
Subspecies and Distribution.
C. s. plebeja (Cabanis, 1875) - extreme NW Angola (coast of Cabinda).
C. s. ansorgei (W. L. Sclater, 1926) - Angolan coastal plain S from W Cuanza Sul (from Sumbe).
C. s. naevia (Strickland, 1853) - NW Namibia.
C. s. herero (Roberts, 1936) - C & S Namibia.
C. s. bradfieldi (Roberts, 1928) - semi-arid Karoo regions in C South Africa.
C. s. waibeli (Grote, 1922) - N Namibia and N Botswana.
C. s. sabotoides (Roberts, 1932) - C & S Botswana, W Zimbabwe and NW South Africa (North-west Province).
C. s. sabota (A. Smith, 1836) - highveld savanna in E Botswana, Zimbabwe and E South Africa.
C. s. suffusca (Clancey, 1958) - SE Zimbabwe, S Mozambique, and lowveld of South Africa and Swaziland.



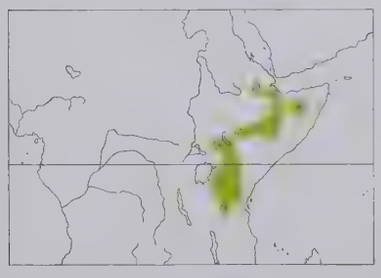
Descriptive notes. 14-15 cm; 21-31 g. Medium-sized lark with prominent pale supercilium, giving capped appearance. Nominate race has dark eyeline, thin black moustachial stripe; neck buffish, lightly streaked; mostly buffish-brown to rufescent with bold dark brown to blackish streaks above, crown feathers edged buff; scapulars and wing-coverts dark brown, broadly edged light brown to pale rufous; flight-feathers dark brown with narrow buff outer edges, tertials broadly edged rufous and light brown; tail dark brown, outer rectrix with buff outer web; throat white, breast washed light brown and heavily streaked dark brown, rest of underparts whitish, variably washed buffish to brown; eyes brown; bill horn, paler base; legs dull pinkish-brown. Differs from *C. africanoides* in having much bolder streaking above and on breast. Sexes alike. Juvenile is darker above, with pale-tipped feathers, breast spotted rather than streaked. Races differ primarily in upperpart colour and extent of streaking (typically are paler and less streaked in more arid areas), also in bill size (short and fairly slender in E, longer and heavier in W): *suffusca* is darker than nominate, upperpart streaking almost black; crown, mantle and scapulars duller and less rusty brown; *ansorgei* is pale and less streaked above; *plebeja* is somewhat browner than previous; *waibeli* is very pale with heavy dark brown streaks above; *sabotoides* is pale and somewhat pinkish-sandy above, streaks broad and dark; *bradfieldi* is rather pale and generally more sandy than nominate, bill very large (largest of all races); *herero* differs from previous in paler and sandier upperparts, whiter underparts, bill slightly smaller; *naevia* is like last but paler, more yellowish-tinged, with narrower streaking. Voice. Male song long and rambling, usually from elevated perch or in display-flight; accomplished mimic, elements from songs of more than 60 species reported, including dove (Columbidae) wing-clapping; one male included 59 songs and calls from 49 species during single 10-minute display. When alarmed, rapid chattering call, often interspersed with alarm calls of other species.
Habitat. Grassy karoo and variety of savanna habitats, ranging from arid fore-Namib and Kalahari thornveld in N to more mesic acacia (*Acacia*) savanna and mopane (*Colophospermum mopane*) woodland in SE. Prefers grassy areas. In W ("*naevia* group") often associated with rocky ridges, provided that some bush cover present.
Food and Feeding. Variety of insects, including caterpillars, grasshoppers (Acrididae), beetles (Coleoptera), termites (Isoptera) and ants; also seeds of grasses and forbs, and leaves and green stems. In the Namib Desert, seeds comprised 60% of food, insects 40%; in the Karoo, grass seeds made up 69% of all seeds consumed. Not recorded as drinking; all water requirements apparently obtained from food. Feeds on ground, picking items from the soil surface or gleaning from vegetation; occasionally digs for food, especially in W ("*naevia* group"). Moves on to burnt areas within 1 hour of a fire.
Breeding. Breeds in Oct-May, mostly Nov-Jan in E and Feb-Mar in W, associated with later onset of summer rains in W. Monogamous and territorial. Male sings from high perch (top of tree, telephone wire) or in aerial display, 20-50 m high; during display-flight circles over territory, typically does not sing during initial climb. Nest in shallow depression on ground, usually at base of a rock, bush or grass tuft, a cup lined with dry grass and rootlets, typically with domed roof at back and sides, with material woven into overhanging vegetation; in the Kalahari, all nests face S, thus gaining maximum shade. Clutch 2-4 eggs (mean 2·3); incubating bird reluctant to leave nest, and, when it does, may feign injury to distract and lead away potential predators; chicks fed by both parents; no data on incubation and fledging periods.
Movements. Largely resident; may make some local movements in response to rain. Some vagrancy indicated by a record from middle Zambezi Valley, in Zimbabwe.
Status and Conservation. Not globally threatened. Fairly common to common in much of range. Densities of c. 1 individual/ha in E of range, but only 1 bird/10 ha in C Kalahari. Substantial populations occur in protected areas. In some areas may benefit from low-level grazing by livestock, which creates openings in the grass and shrub layers.
Bibliography. Bannerman (1953), Clancey (1964b, 1966a), Dean (1987, 1997, 2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Jones (1997b), Keith *et al.* (1992), Mackworth-Praed & Grant (1962, 1970), Maclean (1970b, 1993a), Nuttall (1993), Penry (1994), Sinclair & Hockey (1996), Tarboton (2001), Vernon (1973), Willoughby (1971).

32. Fawn-coloured Lark

Calendulauda africanoides

French: Alouette fauve **German**: Steppenlerche **Spanish**: Alondra Leonada
Other common names: Fawn Lark/Bushlark

Taxonomy. *Mirafra africanoides* A. Smith, 1836, eastern Cape Colony (= Colesberg), Northern Cape, South Africa.
Formerly placed in genus *Mirafra*, but genetic evidence indicates that it belongs in a distinct clade formed by present genus. Often treated as conspecific with disjunct *C. alopex*, but differs genetically and in structure (shorter bill). Geographical variation largely clinal, plumage colour generally matching regional soil colour, and streaking reduced in more arid areas; races broadly intergrade, and further study may reveal that several of those currently accepted are unsustainable; other named races include *omaruru*, *gobabisensis* and *rubidior* (from various parts of NW & NC Namibia), all synonymized with *harei*, and *austinrobertsi* (from thornveld of Zimbabwe-Botswana-South Africa border region), synonymized with nominate. Six subspecies currently recognized.
Subspecies and Distribution.
C. a. trapnelli (C. M. N. White, 1943) - SE Angola and SW Zambia.
C. a. makarikari (Roberts, 1932) - SW Angola, N Namibia and N & C Botswana.
C. a. harei (Roberts, 1917) - NW & C Namibia.
C. a. sarwensis (Roberts, 1932) - W Botswana.
C. a. africanoides (A. Smith, 1836) - S Namibia, S & E Botswana, W Zimbabwe and N & NE South Africa.
C. a. vincenti (Roberts, 1938) - C Zimbabwe and S Mozambique.



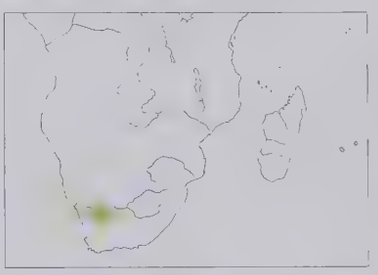
Descriptive notes. 14-16 cm; 21-28 g. Medium-sized lark with broad, long whitish supercilium, contrasting darker ear-coverts bordered pale below, and fairly short, stout pale horn-coloured bill. Nominate race is rufous with brownish streaks above, somewhat darker in E of range ("*austinrobertsi*"), rump less streaked than back; wing-coverts brown with rufous to buffish margins; brown flight-feathers have rufous edges, forming panel on folded wing (and conspicuous in flight); tail dark brown, central feather pair broadly edged rufous, outer pair narrowly edged whitish; white below, breast smudged rufous and lightly streaked darker reddish-brown; eyes pale brown; bill pale yellow-horn, with darker horn-grey upper half of maxilla; legs pinkish to flesh-coloured. Distinguished from *C. alopex* by duller and streaked upperparts, and paler bill in nominate; from *C. sabota* by less streaked face and breast, rufous wingpanel. Sexes alike, female on average slightly smaller. Juvenile has buff-fringed upperpart feathers with darker centres, appearing scaled, outer tail more broadly edged white. Races differ mainly in plumage colour and degree of streaking: *harei* is somewhat paler and less streaked than nominate; *sarwensis* is paler and sandier-coloured than previous, more buffish below, breast barely streaked; *makarikari* is slightly paler than last, more greyish above and below; *trapnelli* differs from previous in being darker, browner and more heavily streaked above; *vincenti* is usually grey or greyish with heavy dark streaking above, buff below. Voice. Typical song a rapid, accelerating series of rather high-pitched, scratchy notes lasting 3-4 seconds, repeated rather monotonously, from elevated perch, usually small tree or bush, or in aerial display; also mimics calls of other birds. Alarm call at nest "peek".
Habitat. Typically on sandy soils in semi-arid savanna and more mesic broadleaf woodland.
Food and Feeding. Insects and seeds. Grass seeds make up 54% of seeds consumed in the Karoo. Forages on ground, often digging in soft sand with its bill.
Breeding. Mostly in Sept-Apr, with peak in Nov-Feb, but breeding can occur at any time, especially in arid W, where triggered by rainfall. Monogamous and territorial; defends territory throughout year, although singing decreases in non-breeding season. Male has protracted aerial display lasting several minutes, circles 15-30 m above ground, with exaggerated wingbeats; also, sometimes confronts rival male on ground, making mock charges and standing with tail cocked, wings drooped, and raising and lowering crown feathers. Nest in shallow scrape in ground at base of a bush or grass tuft, lined with grass and rootlets, almost invariably domed, with nest material woven into sheltering plant; roof built first, then extended down to form cup lining, occasionally only a small raised rim constructed at back of nest, usually a broad "apron" of nest material outside entrance; nests usually face S or E, apparently to be shaded from sun. Clutch 2-4 eggs (mean 2·4); hatching synchronous, suggesting that incubation starts only when clutch complete, incubation period 12 days; chicks fed by both parents, remain in nest for 12-14 days; when nest approached, parents give alarm call and may perform fluttering display-flight to distract intruder. Breeding success in the Kalahari roughly 30%, with 73% of eggs hatching, 42% of chicks fledging.
Movements. Largely resident; some local movements indicated by records of pale birds (from the Kalahari) in E Botswana during drought years.
Status and Conservation. Not globally threatened. Common and fairly widespread in much of range; more local in E. Densities of up to 1 individual/ha in the Kalahari, but only 1 bird/40 ha in *Burkea* woodland in Limpopo Province of South Africa. Large populations occur in protected areas.
Bibliography. Benson *et al.* (1971), Bishop *et al.* (1992), Clancey (1966b), Dean (1997, 2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), Lloyd (1998), Mackworth-Praed & Grant (1962), Maclean (1970a, 1970b, 1993a), Nuttall (1992), Penry (1994), Sinclair & Hockey (1996), Tarboton (1980, 2001), Vernon (1973), White (1965), Winterbottom (1965).

33. **Foxy Lark**

Calendulauda alopex

French: Alouette abyssinienne **German**: Fuchslerche **Spanish**: Alondra Vulpina
Other common names: Abyssinian Lark/Bushlark

Taxonomy. *Mirafra alopex* Sharpe, 1890, Somalia.
Formerly placed in genus *Mirafra*, but genetic evidence indicates that it belongs in a distinct clade formed by present genus. Often treated as conspecific with disjunct *C. africanoides*, but differs genetically and in structure (longer bill). Nominate race very distinctive, separated geographically from *intercedens*; the two may represent different species. Described races *macdonaldi* (S Ethiopia) and *longonotensis* (E Uganda, W Kenya) considered synonymous with latter. Two subspecies recognized.
Subspecies and Distribution.
C. a. alopex (Sharpe, 1890) - N Somalia and extreme E Ethiopia.
C. a. intercedens (Reichenow, 1895) - E & S Ethiopia, immediately adjacent NW & SW Somalia, E Uganda, Kenya and N Tanzania.



Descriptive notes. 14-16 cm; c. 24 g. Medium-sized lark with broad, extensive pale supercilium that contrasts with darker ear-coverts and lores. Nominate race is distinctive, plain chestnut above, with any streaking restricted to dark feather shafts, supercilium buffy; dark brown flight-feathers have broad rufous edges, forming panel on folded wing (and conspicuous in flight); tail dark brown, central feather pair broadly edged rufous or paler brown, outer pair narrowly edged buffy or whitish; light buffy below, breast washed rufous and with a few darker chestnut streaks; bright rufous underwing (distinctive in flight); eyes brown; bill dark grey or horn, pale pinkish base of lower mandible; legs pale greyish-pink. Sexes alike. Juvenile has pale-fringed upperpart feathers, more diffuse spots on breast. Race *intercedens* is very different, supercilium white, lores blackish, dark brown and heavily streaked above, dark brown streaks or chevrons on breast and sometimes rufous wash on breast side, variable, upperpart feathers broadly edged rich rufous-chestnut or paler sandy brown, rufous birds (more frequent at lower elevations) richer buff below, sometimes treated as two morphs but all birds in fresh plumage noticeably more rufous, also some regional variation, on average paler and less streaked in more arid areas; very like *Mirafra gilletti* but typically less rufous, with broader streaks above, no contrast between rump and tail-coverts, rufous-edged flight feathers, darker brown chest streaks; in SW Kenya (Nakuru S to Loita Plains) also a rare grey morph which is almost blackish above in worn plumage. Voice. Song (race *intercedens*) a short, hurried, rather thin verse, similar to that of *C. africanoides*, usually given from top of small tree or other elevated perch, or in short song-flight; includes mimicry of calls of other birds, e.g. cisticola (*Cisticola*) alarm, scrub-robins (*Cercotrichas*) and tits (*Parus*). Song of nominate poorly known; reported as "peculiarly sweet", uttered during aerial display.
Habitat. Almost invariably found on sandy soils. Nominate race in open grassland with scattered shrubs and termite (Isoptera) mounds, as well as small clearings in dense thorn-scrub. Race *intercedens* occurs in savanna and open grassland with scattered acacia (*Acacia*) shrubs and trees, from 500 m to 1800 m. Nominate in more arid scrub and at lower elevations (600-750 m) than adjacent populations of *intercedens* (1200-1650 m).
Food and Feeding. Insects and seeds. Forages on ground.
Breeding. Breeds in Mar-Jun. Probably monogamous; occurs singly or in pairs throughout year. Male has short aerial display. Nest and eggs not described; probably much as for *C. africanoides*.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Common to locally common in suitable habitat.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Benson (1946a), Byaruhanga *et al.* (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Short *et al.* (1990), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

34. **Red Lark**

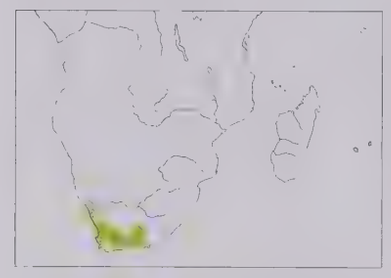
Calendulauda burra

French: Alouette ferrugineuse **German**: Kalaharilerche **Spanish**: Alondra Roja
Other common names: Ferruginous Lark, Sand Lark(!)

Taxonomy. *Ammomanes burra* Bangs, 1930, Great Namaqualand, South Africa.
Originally described as *Alauda ferruginea*, but that name invalid, as preoccupied. Formerly placed in genus *Ammomanes* on the basis of plain back and stout bill. Forms a superspecies with *C. albescens*, *C. barlowi* and *C. erythrochlamys*. Geographical variation in coloration and degree of upperpart streaking largely linked to soil type; brownish birds with streaked back (from Brandvlei area) named as race *harei* and others with more heavily streaked underparts (from Vanwyksvlei) as *aridula*, but all populations intergrade, and plain-backed and streak-backed birds breed together in some areas; further, although some variation in cytochrome *b* gene sequences, haplotypes are mixed throughout population with exception of E dune form ("*aridula*"), which also unusual in being the only form with any streaking on flanks. Treated as monotypic.
Distribution. Bushmanland, in NW Northern Cape, South Africa.

Descriptive notes. c. 19 cm (male 5-11% larger than female); male 37-43 g, female 32-38 g. Fairly large, chunky lark with long, heavy tail. Has whitish supercilium, dark loral line, white patch below eye, dark moustachial and malar stripes enclosing white submoustachial stripe; crown and upperparts variable, from plain brick-red (on red sands in R Koa Valley and E around Vanwyksvlei) to browner with variable darker streaking (on shale and clay soils); whitish below, with strongly contrasting large dark brown streaks on breast, rarely extending faintly to flanks ("*aridula*"); eyes brown; bill dark horn, paler base; legs dull flesh-brown. Sexes alike in plumage. Juvenile has white-tipped upperpart feathers with blackish subterminal bars, breast streaks rounder, more diffuse. Voice. Male song, in aerial display or from elevated perch or ground, a stereotyped short series of notes lasting 1·1·5 seconds, "tip tip tip cher-r-r-r", superficially similar to that of *C. albescens* but deeper and slower, and with significant difference in structure, leading notes and, especially, terminal trill more complex, trill typically comprising 3 repeated multi-element notes; regional dialects, but different songs also given at same sites, and one male recorded as singing at least two types; within each bout, each male sings only one song type, with different birds synchronizing types. Also has chittering alarm call, elements of which incorporated into song when male agitated.
Habitat. Sand dunes, including old, stabilized dunes, also clayey, shale-derived soils mostly on alluvial plains. Occurs in dwarf shrublands and vegetated dunes, preferring areas with large-seeded grasses.
Food and Feeding. Wide range of invertebrates, including beetles (Coleoptera), caterpillars, grasshoppers (Acrididae), ants, termites (Isoptera), spiders, ticks (Acarina); also seeds of grasses and other plants; fruits sometimes taken from bushes. Prefers large, smooth seeds; those of grasses make up only 27% of seeds consumed. At one nest, bagworm caterpillars formed almost half of the items fed to chicks; parents removed these from the silken sheaths by beating and shaking them. Feeds on ground; frequently digs in the ground with its heavy bill, but also picks food from soil surface or from vegetation. Not recorded as drinking water.
Breeding. Nesting records scattered through year, with peaks in Aug-Oct in W and Mar-May in E. Territorial and monogamous; occurs in pairs and male sings throughout year. Male performs song flight with heavy, fluttering beats, often with trailing legs, 10-20 m above territory. Nest a cup lined with dry grass leaves and seed awns, with partial or complete domed roof, once including moulted reptile skin, well concealed on ground at base of a grass tuft. Clutch 2-3 eggs; incubation period not known; parents circumspect when approaching nest, land 10-20 m away and walk up to it; chicks brooded by female when small, fed by both parents, food delivered 8 times per hour in early morning; fledging period unknown.
Movements. Resident, but at least some local movement, possibly by immatures, indicated by occasional records outside its normal restricted range, e.g. two specimens collected in adjacent S Namibia.
Status and Conservation. VULNERABLE. Scarce to uncommon or locally common. Patchily distributed within a small range covering maximum area of 72,000 km^2. Average density estimated at 1 pair/30 ha, giving total population of 9400 individuals; decreasing, primarily as a result of habitat loss caused by overgrazing by livestock, especially in sensitive dune fields; has disappeared from dunes where grazing by cattle has removed grass cover. Those inhabiting the E dune fields around Vanwyksvlei form the most distinctive population and are probably the most severely threatened, having disappeared from several areas. Nevertheless, it remains locally common in some areas, with singing males defending territories of less than 10 ha in favoured habitat. Signifi-

cant populations are protected in private reserves, notably the Black Mountain Mine Nature Reserve (800 pairs), Mattheusgat Conservation Area (250 pairs) and Bitterputs Conservation Area (200 pairs). Conservation targets include the promotion of beneficial farming practices and the monitoring of grazing pressure in core areas of its range.



Bibliography. Barnes (2000), Brooke (1984b), Collar & Stuart (1985), Collar *et al.* (1994), Crowe *et al.* (1994), Dean, W.R.J. (1989b), Dean, W.R.J. *et al.* (1991), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans (2000b), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), Lawson (1961), Mackworth-Praed & Grant (1962), Maclean (1993a), Myburgh & Steyn (1989), Ryan & Bloomer (1997), Ryan *et al.* (1998), Sinclair & Hockey (1996), Stattersfield & Capper (2000), Tarboton (2001).

35. Karoo Lark

Calendulauda albescens

French: Alouette du Karroo **German**: Karoolerche **Spanish**: Alondra del Karoo

Taxonomy. *Alauda albescens* Lafresnaye, 1839, Blouberg, Cape Town, South Africa.
Forms a superspecies with *C. burra*, *C. barlowi* and *C. erythrochlamys*, and is basal within this group. Hybridizes with *C. barlowi* in NW of range (narrow zone between Port Nolloth and R Orange). Geographical variation marked in Northern Cape, with switch from coastal race *codea* to inland *guttata* remarkably sharp (complete replacement within a few kilometres) and few intermediates; otherwise, clinal variation between races broad in some areas; other named taxa are *saldanhae*, which is an intergrade between nominate and *guttata*, and *calviniensis*, which is intermediate between latter and *karruensis*. Four subspecies recognized.
Subspecies and Distribution.
C. a. codea (A. Smith, 1843) - Port Nolloth S to Elands Bay, in NW South Africa.
C. a. albescens (Lafresnaye, 1839) - Saldanha Bay S to Cape Town.
C. a. guttata (Lafresnaye, 1839) - W parts (except coastal areas) of Northern Cape (S from Richtersveld) and Western Cape.
C. a. karruensis Roberts, 1936 - C Karoo.

Descriptive notes. c. 17 cm (male 3-7% larger); male 27-33 g, female 25-29 g. Medium-sized lark with slender, slightly decurved bill and relatively long tail. Nominate race has white supercilium, dark loral line, white area around eye, narrow black malar streak; crown and upperparts grey-brown, heavily streaked dark; wings and tail dark brown, wings with narrow buff edges, outer pair of rectrices with very narrow pale outer edge; white below, heavily streaked blackish from breast to upper belly, narrower streaks on flanks; eyes brown; bill dark horn, with paler base; legs dull pinkish-horn. Distinguished from similar *C. barlowi* mainly by much heavier streaking, also smaller size, with more delicate head and bill. Sexes alike in plumage. Juvenile has upperpart feathers tipped pale cream with dark brown subterminal bars, breast streaks more rounded and diffuse. Races differ primarily in upperpart coloration, richer inland (varying to match soil colour): *codea* is more sandy-grey above than nominate; *guttata* is rufous; *karruensis* is rich chocolate-brown. Voice. Male song, in aerial display or from prominent perch or ground, a repeated, stereotyped phrase of 2-5 staccato notes followed by rather buzzy trill, "tip tip tip zree trrrrr", varies regionally but always faster and higher-pitched than those of other members of superspecies; duration 1·1·5 seconds, shorter than *C. barlowi* and *C. erythrochlamys*, and with two distinct components in terminal trill; where studied, several song varieties at a site, with most males using same song at once. Both sexes also utter shorter "eezer eeit" call, in flight or from perch, and low-pitched chittering alarm from ground or low bush.
Habitat. Inhabits shrubland and well-vegetated dunes, usually on sandy soils. Occurs in coastal strandveld, arid fynbos and karoo scrub, but typically absent from sand-plain fynbos. Generally avoids rocky areas, but found in small sandy pockets among rock outcrops. In area of range overlap with *C. barlowi*, present species occurs in areas with denser, taller vegetation than those inhabited by that species.
Food and Feeding. Diet mostly insects, including grasshoppers (Acrididae), caterpillars, beetles (Coleoptera), termites (Isoptera), mantids, bugs (Hemiptera), dipteran larvae and ants; also spiders, and even snails; also takes seeds, fruits and flowers, occasionally also fruit from low bushes. Grass seeds make up only 13% of seeds consumed. Feeds on ground, digging vigorously in sand with its bill, or gleaning insects from vegetation. Feeds on termites at fresh aardvark (*Orycteropus afer*) diggings. Not recorded as drinking water.
Breeding. Nests in Jul-Nov; may not breed at all in dry years. Territorial and monogamous; male sings throughout year, but mostly in spring breeding season. Male has protracted aerial display 10-30 m above territory, with flight heavy and fluttering, often with legs trailing. Nest built by female, cup-shaped, usually with partial or complete domed roof and side entrance, lined with dry grass and other vegetation, including cotton-like seeds of *Eriocephalus*, placed in depression in ground at base of a bush or grass tuft. Clutch 2-3 eggs (mean 2·6); no data on incubation period; chicks fed by both parents, with insects, leave nest before able to fly, seeking shelter in vegetation; no information on fledging period.
Movements. Resident.
Status and Conservation. Not globally threatened. Common, especially in W of its range. Although coastal populations have suffered loss of habitat through resort development and diamond-mining activities, they remain abundant. Inland populations may have been adversely affected by overgrazing, because they favour areas with more cover; they have lost habitat to crop-farming along dry watercourses in the Karoo.

Bibliography. Cohen (1999), Crowe *et al.* (1994), Dean (1997), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), Lawson (1961), Macdonald (1953), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Maclean (1993a), Ryan, P.G. (1996), Ryan, P.G. & Bloomer (1997), Ryan, P.G. *et al.* (1998), Sinclair & Hockey (1996), Tarboton (2001), Vincent (1946), White (1957b).

36. Barlow's Lark

Calendulauda barlowi

French: Alouette de Barlow **German**: Barlowlerche **Spanish**: Alondra de Barlow

Taxonomy. *Pseudammomanes barlowi* Roberts, 1937, 8 miles [c. 13 km] west of Aus, Namibia.
Forms a superspecies with *C. burra*, *C. albescens* and *C. erythrochlamys*; sister-species to last of those, with no known range overlap between the two. Recently split from *C. albescens* on grounds of genetic, morphological and vocal evidence; hybridizes with it in S of range (narrow zone between R Orange and Port Nolloth). Geographical variation linked to soil type (pale sands on coast, redder inland); differentiation marked in SW of range, with coastal *patae* replaced by inland *cavei* over distance of just a few kilometres and intermediates scarce; nominate intergrades with latter race. Three subspecies recognized.
Subspecies and Distribution.
C. b. barlowi (Roberts, 1937) - SW Namibia from S of R Koichab (inland of Lüderitz) E to Aus.
C. b. patae (Macdonald, 1953) - coastal sands from SW Namibia (Lüderitz) to extreme NW South Africa (Port Nolloth).
C. b. cavei (Macdonald, 1953) - inland part of coastal plain from extreme SW Namibia (S from Aus) to NW South Africa (R Holgat).

Descriptive notes. 18 cm (male 4-8% larger but 14% longer-billed than female); male 27-36 g, female 25-31 g. Medium-sized lark with relatively large head and long bill. Nominate race has whitish supercilium and area around eye, dark loral line, narrow dark malar streak; rufous above, lightly streaked darker; brown wings and tail, broad sandy margins of tertials and central rectrices; white below, breast spotted brown; eyes brown; bill dark horn-grey above, slightly paler below; legs dull pinkish-brown. Distinguished from superficially similar *C. albescens* by plain flanks and less streaking above, larger size, appreciably longer bill (especially male), also bigger-headed appearance, with thicker "bull-neck"; from *C. erythrochlamys* by shorter legs, more streaked upperparts, brown (not rufous) breast spots. Sexes alike in plumage. Juvenile has cream-tipped upperpart feathers and more diffuse breast spots. Race *cavei* is darker and more heavily streaked than nominate; *patae* is pale sandy-grey above (matching colour of pale coastal sands). Voice. Male song lasting 1·5-2 seconds, 6-9 leading notes and a simple, rapid terminal trill, intermediate in length and structure between those of *C. albescens* and *C. erythrochlamys* but pitch significantly lower and trill rate slower than both; immediately N of R Orange, males also give peculiar "rattle song", which has no obvious homologues in other species. Both sexes have variety of other calls, including a rattle alarm.
Habitat. Sandy plains with dwarf shrublands and grassy dunes, favouring more open and shorter vegetation than that preferred by *C. albescens*. Closely associated with *Euphorbia gummifera* throughout much of range.
Food and Feeding. Insects and seeds. Forages on ground, digging in soft sand with its bill, or gleaning prey from sand surface or from vegetation. Not known to drink water. Shelters in shade of bushes during hottest part of day.
Breeding. Little known. Nests with eggs found in Oct, and displays observed chiefly in Aug-Nov; apparently does not breed every year, e.g. very little singing activity and no evidence of breeding in area S of R Orange in exceptionally dry year of 1998. Monogamous and territorial. Only two nests found, domed cup placed in shallow depression in ground at base of bush or grass tuft. Clutch 2 eggs; no data on incubation and fledging periods, although likely to be much as for *C. erythrochlamys*.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common in areas with adequate vegetation cover. Has maximum range of only 18,000 km², most of which falls within restricted-access zones, set aside as buffers to protect coastal diamond-mining areas on each side of R Orange mouth; this currently affords the species high levels of protection, but, as diamond resources become exhausted, there is increasing pressue to open these areas for grazing by small stock. Has disappeared from some areas near Aus, apparently as a result of overgrazing.

Bibliography. Anon. (1997d, 1999c), Barnes (2000), Bridgeford *et al.* (2000), Cohen (1999), Fishpool & Evans (2001), Harrison *et al.* (1997), Keith *et al.* (1992), Lawson (1961), Macdonald (1953), Mackworth-Praed & Grant (1962), Maclean (1957), Ryan, P.G. (1996), Ryan, P.G. *et al.* (1998), Sinclair & Hockey (1996), Sinclair & Ryan (2003), Tarboton (2001).

37. Dune Lark

Calendulauda erythrochlamys

French: Alouette à dos roux **German**: Rotdünenlerche **Spanish**: Alondra de las Dunas
Other common names: Aristida Lark, Red-backed Lark

Taxonomy. *Alauda erythrochlamys* Strickland, 1853, near Walvis Bay, Damaraland, Namibia.
Forms a superspecies with *C. burra*, *C. albescens* and *C. barlowi*; is sister-species to last of those, and no known range overlap between the two. Monotypic.
Distribution. WC Namibia: between R Kuiseb (Walvis Bay) and R Koichab (Lüderitz).

Descriptive notes. 17-18 cm (male 4-8% larger but 19% longer-billed); male 26-33 g, female 25-29 g. Long-legged, medium-sized lark with relatively plain plumage. Has whitish supercilium and area around eye, dark loral line, narrow dark malar streak; sandy rufous above, minimal streaking, tertials and central tail feathers typically with dark central streaks limited to feather shaft; off-white below, a few small pale sandy-rufous streaks on breast; eyes brown; bill horn-coloured with darker upper half of maxilla, paler base; legs dull pink-brown. Distinguished from very similar *C. barlowi* by on average longer legs and shorter bill, almost unstreaked upperparts, fewer, smaller and paler breast streaks. Sexes alike in plumage. Juvenile has pale buff feather tips on upperparts and more prominent breast spots. Voice. Male song, during aerial display or from ground or a bush, distinctive, a long series of 10-13 simple notes followed by brief whistle and then rapid trill, duration 2-2·5 seconds; typically, more leading notes than songs of other taxa in the superspecies. Male also utters shorter series when nesting. Both sexes give rattling contact or alarm call.
Habitat. Restricted to the Namib dune system and adjacent sandy riverbeds. Usually found in areas with at least some vegetation, notably *Stipagrostis* grasses and naras melons (*Acanthosicyos*

horridus), reaching greatest densities in dry riverbeds. Roosts in grass clumps on upper dune slopes at night and during hot part of the day.

Food and Feeding. Diet a mix of insects, spiders and seeds. Insects include ants, termites (Isoptera), grasshoppers (Acrididae), beetles (Coleoptera), caterpillars; seldom takes the conspicuous and aggressive ant *Camponotus detritus*. Feeds on the ground, with running strides of up to 19 cm; maximum stride-length increased with increasing sand temperature. Searches base of vegetation clumps, reaching up to glean insects, and lands on grass tufts to dislodge seeds. Often digs in the sand with its bill, making small craters. Also recorded as leaping upwards or even undertaking brief hawking flights to catch insect prey. Most foraging in morning and late afternoon, pair-members typically remaining close together. At one site, foraging follows predictable pattern, with birds taking insects on dune slopes, then digging for seeds in inter-dune slacks; this pattern was not altered despite 6 years of drought which significantly reduced density of seeds (although lark density decreased over this drought period). Average field metabolic rate (estimated by using doubly labelled water) 97 kJ/day for males and 88 kJ/day for females; both basal metabolic rate and daily energy expenditure are typical for a bird of this size, suggesting that species has not reduced activity levels to cope with extremely arid environment. The high basal metabolic rate may be needed to counter cold weather in winter, although total evaporative water loss is less than expected for a mid-sized passerine. Most of its water requirements apparently obtained from food, as it rarely visits water to drink. Daily water influx estimated to be 5·6 g; this can readily be met with diet of insects, which would supply 10 g of preformed water, but not with seeds (only 0·8 g); diet of c. 20-30% insects required to meet daily water budget, through combination of preformed and metabolic water, without resorting to other water sources. Circumstantial evidence that proportion of insects in diet increases in summer months, when water demands higher.

Breeding. Breeds opportunistically, after rain; recorded virtually throughout year, but mostly Jan-Apr; normally regarded as double-brooded, but may raise 1-4 broods. Monogamous and territorial. Male sings throughout year, but mostly in association with breeding activity, in aerial display or from elevated perch, occasionally from ground. Nest built by female, taking 7-9 days, at base of a grass tuft or other vegetation, a deep cup usually thickly lined with grasses, other vegetation and sometimes hair, feathers or reptile skin, often held together with spider webs, typically domed, with side entrance usually facing S or E (presumably to avoid excessive heat). Clutch 1-2 eggs (mean 1·9); usually re-lays after breeding failure, often recycling material from old nest to build new one; incubation solely by female, starting when clutch complete, period 13-14 days, incubation fairly costly activity as female energy expenditure virtually identical to that when brood-feeding; chicks fed by both parents, with insects, 14 feeds per hour for small chicks, four per hour for larger ones, nestling's feathers break out of sheaths on day 7, fully feathered by 11-12 days (traces of down still present); at end of chick-rearing period female does slightly more work than male, increasing her food intake by 64% (compared with 58% for male); young leave nest after 12-14 days, barely able to flutter, remain hidden in vegetation. Breeding success fairly low: in one study 0·38 fledglings per nest (61% of eggs hatched, 45% of chicks fledged), in another study only one of 13 pairs fledged young. Recorded longevity 6 years.

Movements. Resident; three individuals were retrapped after 5-6 years at same locality as that where first ringed as adults.

Status and Conservation. Not globally threatened. Locally fairly common, but always at relatively low densities. Patchily distributed; linked to distribution of vegetated dunes, and has relatively small total range. The species is afforded a high level of protection, however, because virtually its entire range falls within the Namib-Naukluft National Park.

Bibliography. Boyer (1988), Bridgeford *et al.* (2000), Cox (1983), Crowe *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), Lawson (1961), Mackworth-Praed & Grant (1962), Maclean (1993a), Pollard (1998), Ryan, P.G. PLATE 56

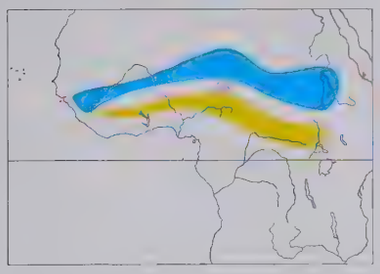
inches 4

cm 10



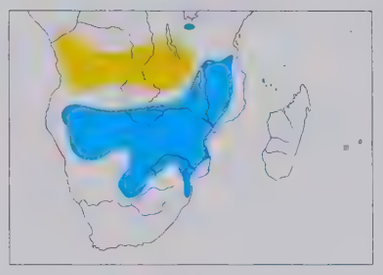
Genus *PINAROCORYS* Shelley, 1902

38. **Rufous-rumped Lark**

Pinarocorys erythropygia

French: Alouette à queue rousse **German**: Rotbürzellerche **Spanish**: Alondra Colirrufa
Other common names: Rufous-rumped Bushlark, Red-tailed Lark

Taxonomy. *Alauda erythropygia* Strickland, 1852, Kordofan, Sudan.
Often placed in genus *Mirafra*, but distinctive in terms of structure, plumage (including slight sexual dimorphism) and migratory behaviour; no genetic material has been sequenced. Forms a superspecies with *P. nigricans*, and sometimes considered conspecific. Monotypic.
Distribution. Breeds in savannas from N Ivory Coast E to S Sudan and N Uganda; migrates N & NW to Sahel and arid savanna from Sierra Leone E to N Niger, N Chad and NC Sudan.



Descriptive notes. 18 cm; 30 g. Distinctive, medium-large, slender, thrush-like lark with striking facial pattern; frequently dangles its legs in flight. Has supercilium and most of face whitish, dark brown eyestripe, rear ear-coverts, malar stripe and line through cheek; crown and upperparts very dark brown, rump and upper-tail-coverts rufous; primaries edged rufous, secondaries tipped rufous, outer tail rufous; wing feathers with prominent pale edges in fresh plumage; whitish below, flanks and vent washed rufous, breast boldly streaked dark brown; eyes dark brown; bill dark horn, yellowish base of lower mandible; legs pinkish-white. Differs from *P. nigricans* in slightly smaller size, prominent rufous rump and outer tail, rufous-washed lower underparts. Female resembles male, but more rufous on primaries. Juvenile is paler above, with paler rufous feather fringes, underparts washed buff with less prominent streaking. Voice. Male song, in aerial display, a series of piping whistles, "tseoo tseoo" or "tsit-tseoo tsit-tseoo", with occasional buzzy trills; flight call a dry "wree".
Habitat. Breeds in open broadleaf woodland and savanna; mostly in more arid savanna in non-breeding period (May-Sept). Also occurs in fields and open cultivated lands. Attracted to recently burnt areas, where sometimes hundreds gather within hours of a fire.
Food and Feeding. Insects, including grasshoppers (Acrididae). Forages mostly on ground; runs from one spot to another. Often perches on top of a tree when flushed.
Breeding. Little known. Breeds in Dec-Feb. Probably monogamous; territorial. Male sings during aerial display, rising from perch on tree, usually remaining in air for only a few minutes. One nest was in natural depression in side of an earth bank in area of recently burnt grassland, the floor and sides of the hole thinly lined with fibres and burnt grass stems; another was described as sited among grass tufts near a small pool. Clutch 2 eggs; an adult flushed from one nest feigned injury to distract the intruder; no information on parental duties or incubation and fledging periods.
Movements. Intra-African migrant. Typically breeds in more mesic habitats in S of range during Oct-Apr dry season, then migrates N to more arid savannas during May-Sept rainy season. Movements not fully understood, however; some may be resident, e.g. in N Nigeria. Vagrant in Gambia.
Status and Conservation. Not globally threatened. Locally fairly common. Its occurrence in many parts of range is rather erratic from one year to another. A rather poorly known species.
Bibliography. Bannerman (1953), Borrow & Demey (2001), Butler (1905, 1908), Byaruhanga *et al.* (2001), Dean (1979), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Grimes (1987), Keith *et al.* (1992), Mackworth-Praed & Grant (1960, 1970), Nikolaus (1987), Salvan (1968), Serle (1957), Short *et al.* (1990), Stevenson & Fanshawe (2002).

39. **Dusky Lark**

Pinarocorys nigricans

French: Alouette brune **German**: Drosslerche **Spanish**: Alondra Oscura

Taxonomy. *Alauda nigricans* Sundevall, 1850, Aapies River, Pretoria, South Africa.
Often placed in genus *Mirafra*, but distinctive in terms of structure, plumage (including sexual dimorphism) and migratory behaviour; no genetic material has been sequenced. Forms a superspecies with *P. erythropygia*, and sometimes considered conspecific. Two subspecies recognized.
Subspecies and Distribution.
P. n. occidentis Clancey, 1968 - breeds SW DRCongo and N Angola; migrates S as far as Namibia and Mozambique.
P. n. nigricans (Sundevall, 1850) - breeds SE DRCongo, SW Tanzania and NW Zambia; migrates S as far as Namibia and Mozambique.
Descriptive notes. 19-20 cm; male 30-46 g, female 31-41 g. Large, slender, thrush-like lark with striking facial pattern, very dark upperparts and boldly streaked breast. Male has whitish supercilium, circumorbital area, cheek, neck side and moustachial stripe, dark eyestripe, ear-coverts, line through cheek and malar streak; crown and upperparts blackish-brown, prominent pale edges of wing feathers in fresh plumage; whitish below, breast boldly streaked blackish-brown; eyes dark brown; bill dark horn, paler yellow-horn base of lower mandible; legs whitish. Differs from *P. erythropygia* in larger size, dark brown rump and outer tail; most closely resembles Groundscraper Thrush (*Psopocichla litsipsirupa*), but is smaller, with scaled wing-coverts, no pale wingbar in flight. Female differs from male in having less boldly patterned face, is less blackish above, more buffy (less white) below, breast streaks not so dark. Juvenile is browner above, with buffy edges of back and wing feathers, buff-washed underparts with less prominent streaking. Race *occidentis* differs from nominate in having less marked breast streaking, appearing paler below. Voice. Male song, in flight, a rather tuneless, burry "zhreeep" or "drree-up".

Habitat. Breeds in miombo woodland and *Uapaca* savanna, typically where there is rather little ground cover, often in recently burnt woodland; also occurs in short open grassland and in burnt areas on its breeding grounds. In non-breeding season found in more arid woodland and savanna, occupying a wide range of open habitats, including bare fields and roadsides.
Food and Feeding. Mostly insects, a few seeds. Insect prey include both worker and alate termites (Isoptera), beetles (Coleoptera), grasshoppers (Acrididae) and ants. Feeds mostly on the ground. While walking, frequently pauses and flicks open its wings, which has been suggested to aid in flushing insects.
Breeding. Breeds in dry season, Aug-Oct. Singing male displays over territory of c. 2·5 ha. Nest a deep cavity, probably excavated by the bird itself, in side of an earth clod or exposed base of a grass tuft, thinly lined with coarse grass stems, large pieces of bark liberally strewn over area within radius of 0·5 m of nest; both nests found in Angola faced S. Clutch 2 eggs; chicks fed by both parents, which are extremely wary around nest, flying up to top of nearby tree if disturbed; incubation and fledging periods unknown.
Movements. Inter-African migrant. After breeding in C Africa in Jul-Oct dry season, disperses S & E into more open habitats in association with arrival of summer rains. Non-breeding range extends from S Angola across to S Tanzania, and S to C Namibia, N & NE South Africa and S Mozambique; both races occur together on non-breeding grounds. Migrates in small flocks. Most records in South Africa during Dec-Apr, although birds arrive as early as Oct and some remain as late as Jun; farther N in S parts of Africa, distinct peaks in reporting rates in Nov-Dec and Apr-May, presumably linked to passage of migrants; much more marked peak in reporting rates during return migration N in Apr-May suggests that this passage is more synchronized. Periodic irruptions into areas where species seldom occurs in most years. Recent discovery of significant numbers of non-breeding individuals S of L Victoria (in N Tanzania) suggests that post-breeding dispersal also oriented NE.
Status and Conservation. Not globally threatened. Locally common; numbers vary from one year to another in some areas. Rather irregular in many parts of non-breeding range. Despite early reports of breeding S of R Zambezi, most evidence points to breeding being confined to C Africa N of Zambezi; alleged record of nest with 3 eggs in Zululand in Oct not substantiated.
Bibliography. Benson (1959), Benson *et al.* (1971), Clancey (1964b, 1968c), Dean (1974, 2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Jones (1997a), Keith *et al.* (1992), Mackworth-Praed & Grant (1960, 1962, 1970), Maclean (1993a), Martin (1972), Penry (1994), Shaw (1978), Short *et al.* (1990), Sinclair & Hockey (1996), Stevenson & Fanshawe (2002), Tyler (1998), Zimmerman *et al.* (1996).

Genus *AMMOMANOPSIS* Bianchi, 1904

40. **Gray's Lark**

Ammomanopsis grayi

French: Ammomane de Gray **German**: Namiblerche **Spanish**: Alondra de Gray
Other common names: Gray's Sand Lark

Taxonomy. *Alauda grayi* Wahlberg, 1855, between Kuiseb and Swakop Rivers, Damaraland, Namibia.
Traditionally placed in genus *Ammomanes* and in the past thought to form a superspecies with *A. deserti*, but apparent similarities now attributed to convergence. Genetic evidence indicates that it is much closer to *Certhilauda* and *Chersomanes*. Upperpart coloration closely linked to soil colour, darker in N; pale birds reappear on whitish sands in far N of range (S to extreme NW Namibia), may represent an undescribed taxon. Two subspecies recognized.
Subspecies and Distribution.
A. g. hoeschi (Niethammer, 1955) - coastal plain of SW Angola and NW Namibia (S to Cape Cross).
A. g. grayi (Wahlberg, 1855) - coastal plain of C & S Namibia.

Descriptive notes. 14 cm; male 19-27 g, female 17-23 g. Peculiar, compact desert lark with plain, unstreaked plumage, only slight hint of paler supercilium and darker eyestripe; stubby bill. Nominate race is pale sandy brown above, flight-feathers only slightly darker than wing-coverts; central tail feathers pale like back, remainder dark brown with white bases and narrow tips (distinctive in flight); underparts whitish, a few faint streaks on breast side; eyes brown; bill yellowish to pale bluish-grey, darker tip; legs flesh-grey. Differs from *Spizocorys starki* and female *Eremopterix verticalis* in much plainer plumage; distinguished from similar pale desert race of Tractrac Chat (*Cercomela tractrac*) by much heavier bill, shorter legs, completely different stance and gait. Sexes alike. Juvenile has paler feather fringes above (looks slightly scaled), breast lightly mottled, mostly at sides. Race *hoeschi* is darker than nominate, grey-brown above. Voice. Male song, from ground or in display-flight, mostly before dawn or after dusk, a strange, very high-pitched series of short calls and ascending whistle, "tink

Agulhas Long-billed Lark (*Certhilauda brevirostris*); 45. Eastern Long-billed Lark (*Certhilauda semitorquata*); 46. Karoo Long-billed Lark (*Certhilauda subcoronata*); 47. Benguela Long-billed Lark (*Certhilauda benguelensis*); 48. Short-clawed Lark (*Certhilauda chuana*); 49. Greater Hoopoe-lark (*Alaemon alaudipes*); 50. Lesser Hoopoe-lark (*Alaemon hamertoni*); 51. Dupont's Lark (*Chersophilus duponti*).

tink tink wheeeeeer tink tink", and various short whistles, typically ascending in pitch. Contact calls include soft "tew" and series of 3 piping notes.
Habitat. Gravel plains, clayey soils and saltflats with little or no vegetation other than scattered grass clumps or patches of succulents; avoids drifting sands.
Food and Feeding. Seeds, mostly of *Stipagrostis* grasses and various desert forbs, and other vegetable matter; also insects, including *Hodotermes* termites, ants, beetles (Coleoptera), grasshoppers (Acrididae), moths (Lepidoptera), flies (Diptera) and stick-insects (Phasmida); also arachnids (spiders and solifugids). In one study, seeds made up 56% of diet, invertebrates 43% and green vegetable matter 1%. Typically forages with crouched, finch-like posture. Picks food from ground surface, or digs with the bill; also pulls at grass stems to expose the soft bases, which are then eaten. Seldom drinks water, apparently obtaining sufficient water from its food. Seeks shelter from heat by entering rodent burrows; or loses heat by standing on raised rocks or sticks with wings held away from body, and facing into wind. In small groups, usually of 3-4 individuals, during most of year, but up to 130 on occasion.
Breeding. Breeds mostly in Mar-Jun, in association with peak in late-summer rains, but scattered records throughout year suggest that breeding at least partly opportunistic, following local rain events. Breeds mostly in pairs, sometimes co-operatively, e.g. 3 birds feeding a fledged chick; solitary, but several pairs may nest fairly close together. Male has relatively low, undulating display-flight, with wing-whirring preceding vocalizations. Nest in deep hollow in ground, typically lined with thick, insulating mat of fine grasses and grass seedheads (in one case virtually no lining), usually surrounded by narrow "apron" of small stones, which also line nest scrape; often situated on S or SE side of a rock or a grass tuft, which shades nest during hottest time of day; on open plains, nest cup so deep that incubating bird, back of which is level with ground surface, is almost invisible. Clutch 2-3 eggs (mean 2·4); incubation period 12-13 days; chicks fed by both parents, leave nest after c. 10 days, before capable of flight.
Movements. Rather mobile on a very local scale; no evidence of systematic movements. Somewhat nomadic, with groups wandering widely over open plains; gathers in flocks in response to rain events, but never attains the spectacular concentrations of nomadic seed-eating species such as *Eremopterix verticalis*, *Spizocorys starki* or Lark-like Bunting (*Emberiza impetuani*).
Status and Conservation. Not globally threatened. Locally common. Most abundant in E part of the Namib, but occurs W all the way to the coast where suitable habitat available. A large proportion of the species' range is in formally protected areas.

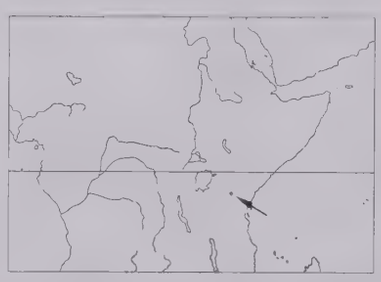
Genus *CHERSOMANES* Cabanis, 1851

41. Spike-heeled Lark

Chersomanes albofasciata

French: Alouette éperonnée **German**: Zirplerche **Spanish**: Alondra Espolada

Taxonomy. *Certhilauda albofasciata* Lafresnaye, 1836, Deelfontein, Northern Cape, South Africa.
Forms a superspecies with *C. beesleyi*; usually considered conspecific, but genetically distinct, widely separated geographically, and lacks sexual plumage dimorphism. Genetic data indicate that N populations are basal, and that, within South Africa, W (coastal) and E (grassland) populations are more closely related to each other than to Karoo populations. Geographical variation mostly in plumage coloration, with fine-scale differences linked to changes in soil colour, resulting in numerous races having been described; differences among many contiguous forms broadly clinal, and further study may demonstrate that several of listed races are unsustainable. Other named races include *longispina* from Angola (W Huíla), synonymized with *obscurata*; *bathoeni* from SE Botswana, merged with *kalahariae*; *bradfieldi* from Great Namaqualand (Langklip), merged with *arenaria*; from W to E in South Africa, *bushmanensis* and *meinertzhageni* are considered synonymous with *garrula*, *baddeleyi* with nominate, *robertsi* and *subpallida* with *alticola*, and *latimerae* with *macdonaldi*. Isolated population in SE DRCongo not yet ascribed to any named race. Ten subspecies recognized.
Subspecies and Distribution.
C. a. obscurata (Hartert, 1907) - SW, C & NE Angola (C plateau, and S Bengula S to Namibe).
C. a. boweni (Meyer de Schauensee, 1931) - NW Namibia.
C. a. erikssoni (Hartert, 1907) - N Namibia.
C. a. barlowi (C. M. N. White, 1961) - NE Botswana.
C. a. arenaria (Reichenow, 1904) - S Namibia and SW South Africa (S to NW & C Karoo).
C. a. garrula (A. Smith, 1846) - W South Africa (Western Cape).
C. a. kalahariae (Ogilvie-Grant, 1912) - C Botswana and N South Africa.
C. a. albofasciata (Lafresnaye, 1836) - SE Botswana and C South Africa.
C. a. alticola Roberts, 1932 - NE South Africa.
C. a. macdonaldi (Winterbottom, 1958) - S South Africa (SE Karoo).



Descriptive notes. 13-14 cm; male 23-34 g, female 20-27 g. Very distinctive lark, with upright posture, slender decurved bill, and short tail with prominent white tips; hind claw remarkably long and straight. Nominate race has buffish supercilium and circumorbital ring, pale rufous-brown ear-coverts; blackish-streaked rufous-brown above, browner or greyer on neck, back feathers with broad dark centres and buff-white tips; wings dark brown, edged buffish; tail dark brown, broadly tipped white (except central rectrices); throat white, contrasting with light rufous-brown to cinnamon underparts, breast sometimes with some darker streaking or mottling (often lacking); eyes brown; bill dark horn above, paler below; legs whitish to pinkish-brown or plumbeous grey. Sexes alike in plumage, female on average smaller and shorter-billed (no overlap in bill length). Juvenile has crown and back feathers tipped white or buff, white-fringed wing-coverts, indistinct dark mottling on breast. Races differ considerably in plumage coloration, generally darker and more rufous in E, becoming paler sandy or ash-grey in arid W; *alticola* is darker than nominate above, light yellowish-brown below; *macdonaldi* is dark and grey-tinged above, greyish below; *garrula* is darker than previous, upperparts well marked with blackish, browner below; *kalahariae* is pale sandy above, pale below; *erikssoni* is greyer and more streaked than previous; *barlowi* is greyer and less streaked than last, paler below, usually fine dark breast streaks; *arenaria* is yellowish-rufous above, streaks narrower, pale below; *boweni* is plain pinkish-sandy above, pale below; *obscurata* is dark, back feathers with very broad black centres and reddish edges, deep rufous underparts. Voice. Typical call a dry trill, "trrri-trrri-trrri-trrr", like that of a plover (Charadriidae), appears to function both for contact among group-members and as territorial song; groups respond strongly to playback of call, sometimes producing almost hysterical trilling chorus.
Habitat. Range of open habitats, from montane grassland to arid Karoo shrublands and to semi-desert and desert plains; also, rather isolated populations on fringes of pans, such as Etosha Pan, in Namibia, and L Makgadikgadi, in Botswana. Often associated with mammal burrows.
Food and Feeding. Mostly insects, including termites (Isoptera), beetles (Coleoptera), ants and moths (Lepidoptera), and arachnids (solifugids); some seeds (of grasses and some forbs) also taken. In the Namib, invertebrates comprised 84% of diet and seeds 16%. Marked sexual size dimorphism may be related to its largely insectivorous diet; larger males had higher frequency of beetles in the diet (81%) than did females (25%). In the Karoo, seeds were relatively scarce in the diet, with no grass seeds recorded at all. Not known to visit watering points to drink; all water requirements apparently obtained from food. Usually occurs in groups of 3-10 individuals; often, one stands sentry on a small bush or termite mound while the others forage. When threatened, takes refuge in mammal burrows, where also seeks shelter from the sun in heat of day.
Breeding. Mostly Jul-Dec in South Africa, although in arid areas breeding stimulated by rainfall and can occur in virtually any season; typically later (linked to later rains), Feb-Apr, in Namibia; in the Kalahari and Bushmanland, eggs laid within a week of even very small rain events (less than 10 mm). Breeds mostly in pairs, sometimes co-operatively; in arid W, records of three birds simultaneously bringing food to nest. Male occasionally performs striking aerial display, rises steeply to c. 6 m, hovers briefly while uttering trill, then glides back to ground with wings held slightly below horizontal. Nest, in one case built by a single adult (presumably female) in c. 5 days, a shallow depression in ground, often at base of a bush or grass tuft, lined with dry grass, stems and rootlets; in arid areas, located in sandy site and typically with "apron" of pebbles, earth clods or twigs on open side, and in arid W usually on E or SE side of a bush, providing shade from afternoon sun; nest rim occasionally decorated with sand-encrusted spider webs, as with *Eremopterix australis* nests. Clutch 2-3 eggs, rarely 4 or 5 (mean 2·6); in arid areas clutch size varies with rainfall, average 2 eggs following small showers, 2·8 after moderate rains, and 3·3 after very good rains (when the only clutches of 4 and 5 eggs were recorded); laying interval 1 day, in one case reported as 2 days; incubation sometimes starts with first egg, sometimes delayed until clutch complete, incubation period 12-13 days; chicks fed by both parents, sometimes assisted by helper, parents call softly on approach to nest, alerting chicks to their presence, wait to remove any faecal pellets after feeding, typically run from nest rather than fly away if disturbed; chicks leave nest 8-12 days (usually 11 days) after hatching, before able to fly, cared for by parents for considerable period; terrestrial predators, such as mongooses (Herpestidae), mobbed with hovering display and calling. In arid W high levels of nest predation, primarily by small mammals (especially mongooses), only 41% of clutches survive to due hatching date, 92% of these eggs hatch, and 65% of broods survive to fledging, giving overall breeding success of only 22% and mean of 0·56 young fledged per attempt; in the Kalahari, success was slightly higher, at 34%.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Common throughout most of range. No data available on densities, but pairs and groups defend rather large territories throughout year. Avoids croplands, and has certainly suffered habitat loss in E of its range in South Africa as a result of expansion of agriculture and sylviculture. Adults subject to predation by Red-necked Falcons (*Falco chicquera*) and Common Fiscals (*Lanius collaris*). Isolated population in SE DRCongo virtually unknown, and racial identity not determined; further work required in order to clarify its taxonomy and status.
Bibliography. Clancey (1962, 1964b), Dean (1997, 2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Herremans-Tonnoeyr & Herremans (1993), Keith *et al.* (1992), Kleynhans & Kleynhans (2000), Lloyd (1998, 1999), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Maclean (1970a, 1970b, 1974b, 1993a), Penry (1994), Sinclair & Hockey (1996), Steyn (1988), de Swardt (1990b), Tarboton (2001), Tieleman *et al.* (2003), White (1957b), Willoughby (1971), Winterbottom (1958).

42. Beesley's Lark

Chersomanes beesleyi

French: Alouette de Beesley **German**: Beesleylerche **Spanish**: Alondra de Beesley
Other common names: Pygmy Spike-heeled Lark

Taxonomy. *Chersomanes albofasciata beesleyi* Benson, 1966, Masai Plains, north of Arusha, north Tanzania.
Forms a superspecies with *C. albofasciata*; usually considered conspecific, but genetically distinct, widely separated geographically, and exhibits a degree of sexual plumage dimorphism. Monotypic.
Distribution. N Tanzania: area just N of Mt Meru.

Descriptive notes. 11 cm; male 27 g, female 22 g. Very distinctive lark with slender decurved bill, short tail with white tip, upright posture; very long and straight hind claw. Male has whitish supercilium and circumorbital ring, pale rufous ear-coverts; crown and upperparts dark brown with pale feather fringes (colour matching that of local soil, and similar to that of local populations of *Pseudalaemon fremantlii* and *Calandrella somalica*); wings dark brown, edged whitish; tail dark brown with broad white tips (except central rectrices); throat whitish, contrasting with light rufous underparts, breast streaked dark brownish; eyes brown; bill dark horn above, paler below; legs pale pink. Distinguished from similar *C. albofasciata* (especially of race *obscurata*) mainly by heavier streaking on breast, smaller size (wing on average 10% shorter). Female is more richly rufous on belly and has fewer, bolder breast streaks. Juvenile has narrower pale feather fringes on upperpart, larger and more diffuse breast streaks, paler (buff)

belly. Voice. Quite high-pitched, slightly nasal chittering call, similar to that of *C. albofasciata*; twanging chirps by adults delivering food to nest.
Habitat. Short-grass plains with no trees or shrubs, at 1400-1550 m. Apparently restricted to two small areas N of Mt Meru, in the rainshadow of Mt Kilimanjaro, where there are tussock-forming grasses with adequate space between tufts (ground cover c. 50%); avoids stony areas.
Food and Feeding. Stomach contents dominated by beetles (of families Curculionidae, Tenebrionidae and Buprestidae), but also contained caterpillars, a large centipede (Diplopoda) and a seed. Fledged young were fed with caterpillars. Forages on the ground; frequently cocks tail, unlike *C. albofasciata*. Occurs in pairs or small groups throughout year, rarely in groups of up to ten individuals.
Breeding. Breeds during long and short rains, Oct-Dec and Mar-Apr. Chicks recorded as fed by at least two adults, but not known if a co-operative breeder. Nest a shallow cup on ground, lined with dry grass and cow dung. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Because of uncertainty about its taxonomic status, conservation status not formally assessed: likely to be Endangered or even Critical. Entire world population confined to two small areas of less than 10 km^2 in extent, situated c. 30-50 km N of Arusha; neither is protected. A reported sighting from Amboseli, in S Kenya, is disputed. The two areas known to be inhabited by this lark are currently grazed by livestock, which may enhance their suitability for the species by maintaining open areas among tussocks; any change in land-use practices, however, could have disastrous effects.
Bibliography. Beesley (1971), Benson (1966), Benson & Forbes-Watson (1966), Keith *et al.* (1992), Lewis & Pomeroy (1989), Moore (1979), Short *et al.* (1990), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Turner (1985), Zimmerman *et al.* (1996).

Genus *CERTHILAUDA* Swainson, 1827

43. Cape Long-billed Lark
Certhilauda curvirostris

French: Alouette à long bec **German**: Kap-Langschnabellerche **Spanish**: Alondra de El Cabo
Other common names: Long-billed Lark (when all members of genus except *C. chuana* lumped as one species)

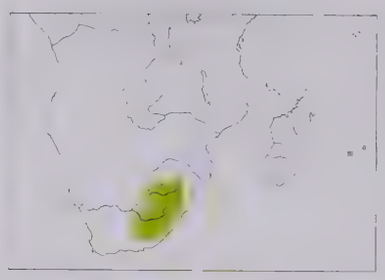
Taxonomy. *Alauda curvirostris* Hermann, 1783, Cape of Good Hope, South Africa.
All members of genus with exception of *C. chuana* formerly treated as a single species, but recent research indicates that they are genetically, morphologically and vocally distinct. Present species and *C. brevirostris* appear to be sister-species (ranges apparently separated by Cape fold mountains, but boundary in Gouda-Tulbagh area not well known), and genetic data suggest that they are closely related to *C. semitorquata*. Range overlaps narrowly with that of *C. subcoronata* in N (on E edge of Namaqualand coastal plain N of Port Nolloth). Bill length increases clinally from N to S, probably linked to softer, sandier substrates in N. Two subspecies recognized.
Subspecies and Distribution.
C. c. falcirostris Reichenow, 1916 - coastal plain from extreme SW Namibia S to W South Africa (S to R Olifants).
C. c. curvirostris (Hermann, 1783) - coastal plain from R Olifants S to Cape Town.

Descriptive notes. 20-24 cm (male on average 12-19% larger than female, with greatest difference in bill length); 40-60 g. Largest lark in S Africa, with long decurved bill, long tail, fairly long legs, narrow pale supercilium and eyering. Nominate race is grey-brown, heavily streaked darker brown, above; white to creamy below, heavy dark streaking on breast, streaks extending less boldly down flanks and belly sides; eyes brown; bill blackish-horn; legs dull pink-brown. Differs from *C. brevirostris* in slightly paler and greyer appearance, larger size, appreciably longer and deeper bill and longer tail. Sexes alike in plumage. Juvenile is browner above, with prominent buff-white tips of feathers, breast more diffusely spotted rufous-brown. Race *falcirostris* is larger, longer-billed and slightly greyer than nominate, with larger, darker and more pronounced teardrop-shaped streaks on breast; distinguished from *C. subcoronata* by cold grey-brown (not rufous) upperparts, white (not creamy) underparts with heavy streaking extending to the flanks. Voice. In S (nominate race), male song, in display-flight or from low perch or ground, "whi-peeeooo", first note much shorter, softer and less far-carrying than second, the initial note shorter and less pronounced than in song of *C. brevirostris*; in N (*falcirostris*), a single, descending whistle, "peeeoooo"; much softer version given while walking or foraging. Also a burry contact call, "irrr-errr".
Habitat. Short coastal scrub (strandveld) and dune vegetation, usually where open areas of sandy soil present. In N of range largely confined to a narrow strip of white coastal dunes. In S occurs widely in extensive cereal fields, but favours fallow fields or recently ploughed or planted lands; in areas with tall, dense crops is largely confined to field edges and roadsides.
Food and Feeding. Diet poorly known; mostly insects, e.g. beetles (Coleoptera) and caterpillars, also a few seeds. Forages by walking on ground, searching at bases of plants, turning over stones and digging in sand and soft soil for larvae and insects.
Breeding. Breeds Aug-Oct. Usually in pairs throughout year. Male sings in all months, at peak intensity in late winter-spring in association with breeding; displaying male flies close to ground, rises near-vertically 10-15 m on closed wings, utters song, then stalls and falls vertically, wings still closed until just before reaching ground, and continues horizontal flight; sometimes 2-3 up-down displays on same flight. Few other details known; clutch 3 eggs.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally common. Occurs always at relatively low densities, c. 1 pair/10 ha. Although much of its coastal habitat in N of range has been disturbed by diamond-mining, it remains common there. In S, population has adapted to intensively farmed croplands, but it tends to occur mostly in fallow fields. Relatively poorly known species; fieldwork required in order to ascertain more about its ecology and breeding biology.
Bibliography. Clancey (1957), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Maclean (1993a, 1999), Ryan & Bloomer (1999), Sinclair & Hockey (1996), Sinclair & Ryan (2003), Uys (1984).

44. Agulhas Long-billed Lark
Certhilauda brevirostris

French: Alouette de l'Agulhas **Spanish**: Alondra de Agulhas
German: Agulhas-Langschnabellerche

Taxonomy. *Certhilauda curvirostris brevirostris* Roberts, 1941, Zoetendalsvlei, Bredasdorp, Western Cape, South Africa.
All members of genus with exception of *C. chuana* formerly treated as a single species, but recent research indicates that they are genetically, morphologically and vocally distinct. Present species and *C. curvirostris* appear to be sister-species (ranges apparently separated by Cape fold mountains, but boundary in Gouda-Tulbagh area not well known), and genetic data suggest that they are closely related to *C. semitorquata*. Possibly overlaps in range with *C. subcoronata* in Breede Valley. Monotypic.
Distribution. Agulhas Plain and Breede Valley, in Western Cape, South Africa.

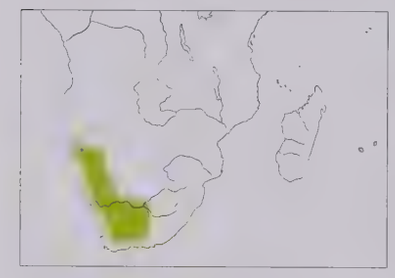


Descriptive notes. 18-21 cm; 35-48 g. Has pale supercilium and eyering; buffish-brown with darker streaks above; pale buffish-white below, dark streaks from breast down to flanks; eyes brown; bill blackish-horn; legs dull pink-brown. Distinguished from *C. curvirostris* by appreciably smaller size, shorter and more slender bill, shorter tail, more buff-brown coloration; from *C. subcoronata* by smaller size, lack of rufous on upperparts, more extensive and uniform streaking, especially on underparts. Sexes alike in plumage, female appreciably smaller. Juvenile has prominent buffy feather tips on upperparts, breast more diffusely spotted. Voice. Male song 2 notes of roughly even duration, "tsuuee peeooo", initial note softer and not so far-carrying as second; sings mostly from dawn until late morning, throughout year. Also burry contact calls.
Habitat. Occurs in fallow fields and recently ploughed fields; appears to avoid areas that are farmed intensively. At edges of range, on less productive soils, occurs also in natural vegetation; favours sandy areas dominated by restios along the coast, and dwarf Karoo shrublands on clay soils in foothills of Breede Valley.
Food and Feeding. Food mostly insects, some seeds. Forages on the ground; sometimes digs with bill, or uses feet to pull at vegetation.
Breeding. Eggs laid in Sept-Oct, young fledge in Oct-Nov. Male aerial display close to ground, then rising and falling vertically 10-15 m on closed wings, calling at peak of ascent; similar to that of *C. curvirostris*. Nest in open cup, usually at base of a small bush or tuft of grass, in some cases rudimentary, with only very thin mat of vegetation lining a depression in ground. Clutch 2-3 eggs (mean 2·7); nothing known about parental duties or incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common but local. Has very small range, covering maximum of only 15,000 km^2. Much of its range has been transformed for agriculture, to the point where there is ongoing debate as to the nature of original vegetation of area. Although fairly common in pastures and fallow fields, it is patchily distributed across Agulhas Plain; reasons for this unknown. Some concern that changes in land-use practices may adversely affect the population.
Bibliography. Barnes (2000), Harrison *et al.* (1997), Fishpool & Evans (2001), Keith *et al.* (1992), Louw (2000), Macdonald (1952b), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Maclean (1993a), Ryan & Bloomer (1999), Sinclair & Ryan (2003), Stattersfield & Capper (2000).

45. Eastern Long-billed Lark
Certhilauda semitorquata

French: Alouette du Transvaal **Spanish**: Alondra de Transvaal
German: Transkei-Langschnabellerche

Taxonomy. *Certhilauda semitorquata* A. Smith, 1836, Orange River (= Colesberg), Northern Cape, South Africa.
All members of genus with exception of *C. chuana* formerly treated as a single species, but recent research indicates that they are genetically, morphologically and vocally distinct. Despite plumage differences, present species most closely related to *C. curvirostris* and *C. brevirostris*; only distantly related to adjacent *C. subcoronata*, ranges abutting over broad distance at karoo-grassland interface (roughly along 24° E longitude). Geographical variation rather clinal. Three subspecies recognized.
Subspecies and Distribution.
C. s. transvaalensis Roberts, 1936 - E South Africa (N Free State, Gauteng, Mpumulanga and N KwaZulu-Natal).
C. s. semitorquata A. Smith, 1836 - E Karoo grasslands of South Africa (Northern Cape, Eastern Cape, Free State, KwaZulu-Natal) and Lesotho.
C. s. algida Quickelberge, 1967 - S part of Eastern Cape.
Descriptive notes. 16-20 cm (male on average 10-14% larger in body measurements, 26% longer bill); 30-48 g. Rather plain plumage, with narrow pale supercilium and eyering; the smallest species in the "*C. curvirostris* complex". Nominate race has crown and upperparts light rufous-brown, only minimally streaked; underparts light buffish, breast faintly streaked and spotted darker; eyes brown; bill blackish-horn; legs dull pink-brown. Differs from *C. subcoronata* in being appreciably smaller and shorter-billed, with less heavy streaking on back and breast. Sexes alike in plumage. Juvenile has prominent buffy feather tips on upperparts, breast more diffusely spotted. Races differ in size, plumage colour and streaking: *transvaalensis* is small, brighter rufous and unstreaked above, only a few small rufous spots on breast, and short, relatively straight bill; *algida* is relatively large, brownish and streaky. Voice. Male song, given throughout year, from favoured rock or in aerial display, a simple, descending "peeoooo", lacking the "inhalation" that precedes song of *C. subcoronata*. Also burry contact calls.



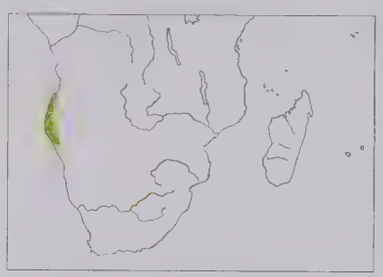
Habitat. Grassland, usually on rocky slopes. **Food and Feeding**. Food primarily insects. Feeds by walking on ground. Most prey apparently detected visually; seldom digs for food, but does probe into bases of grass tufts. **Breeding**. Laying from late Sept to Jan, mainly Oct-Dec. Male aerial display close to ground, then rising and falling vertically 10-15 m on closed wings, calling at peak of ascent. Nest, built solely by female, an open cup lined with dry grass, usually at base of and partially sheltered by a grass tuft or rock; edge of nest often decorated with small stones (15-30 mm diameter), sometimes forming broad "apron" of same size as nest itself. Clutch 2-3 eggs; nestlings fed by both parents; incubation and fledging periods unknown.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Relatively common but patchily distributed. Occurs at low densities even in favoured habitat, as each pair has a large territory. Owing partly to its preference for rocky slopes, which have limited agricultural potential, it remains reasonably common. Nevertheless, its distribution is irregular throughout the grassland biome of South Africa, and this species has probably been adversely affected by widespread habitat transformation.
Bibliography. Clancey (1964b), Harrison *et al.* (1997), Keith *et al.* (1992), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Maclean (1993a), Quickelberge (1967), Ryan & Bloomer (1999), Sinclair & Ryan (2003).

46. Karoo Long-billed Lark

Certhilauda subcoronata

French: Alouette du Namaland **Spanish**: Alondra Namaqua
German: Karoo-Langschnabellerche

Taxonomy. *Certhilauda subcoronata* A. Smith, 1843, Deelfontein, Northern Cape, South Africa.
All members of genus with exception of *C. chuana* formerly treated as conspecific, but recent research indicates that they are genetically, morphologically and vocally distinct. Although genetic data suggest that present species has no close relatives within the complex, it is very similar to *C. benguelensis* in morphology and vocalizations. Range overlaps narrowly with that of *C. curvirostris* in NW, and abuts that of *C. semitorquata* at karoo-grassland interface (roughly along 24° E longitude); possible overlap with *C. brevirostris* in S (Breede Valley). Exhibits strong N-S clines in size, colour and streaking. Race *damarensis* possibly belongs with *C. benguelensis*, but plumage and morphology suggest that it represents N end of cline of reduction in size and streaking of present species (by comparison, S race *kaokoensis* of *C. benguelensis* slightly larger, darker and more streaked); this argument supported by a gap in atlas records S of Brandberg, which approximates with geographical boundary between the two taxa. Race *gilli* intergrades with nominate, and *bradshawi* with *damarensis*. Four subspecies recognized.
Subspecies and Distribution.
C. s. damarensis (Sharpe, 1904) - C Namibia.
C. s. bradshawi (Sharpe, 1904) - S Namibia and NW South Africa (Bushmanland).
C. s. subcoronata A. Smith, 1843 - W South Africa (from Kenhardt area S to C Karoo).
C. s. gilli Roberts, 1936 - S Karoo (from Touwsrivier E to Beaufort West).



Descriptive notes. 18-22 cm (male on average 12-14% larger in body measurements, 28% longer bill); 31-55 g. Moderately streaked plumage, with narrow pale supercilium and eyering; the second-largest species in the "*C. curvirostris* complex". Nominate race has crown and upperparts rufous, nape paler and greyer, all with rather limited dark streaking; whitish below, breast spotted and streaked dark brown, streaks extending faintly to flanks; eyes brown; bill blackish-horn; legs dull pink-brown. Best distinguished from *C. curvirostris* and *C. brevirostris* by rufous upperparts, contrasting greyish nape, rather limited streaking (especially on flanks); from *C. semitorquata* by larger size, longer bill, more prominent streaking above and below. Sexes alike in plumage. Juvenile has prominent buff-white feather tips above, breast more diffusely spotted. Races differ mainly in size, colour and degree of streaking: *bradshawi* is smaller, less streaked and brighter rufous than nominate; *damarensis* is still smaller, and much paler; *gilli* is largest, darkest and most heavily streaked, with dark rufous-brown upperparts. Voice. Male song, given throughout year, a descending whistle, "peeoooo", in S of range preceded by soft note that sounds at close range like an inhalation, "wi-peeoooo". Also a burry contact call uttered by female, perhaps also by male.
Habitat. Semi-arid Karoo shrublands and fore-Namib mountains; especially abundant in the Nama Karoo. Favours rocky areas, but also found on stony and clayey soils; generally avoids sandy areas.
Food and Feeding. Food includes wide variety of insects and spiders; also seeds, fruits and small corms, but apparently few, if any, grass seeds. Forages on the ground. Searches bases of plants, digs in softer soils, turns over stones; reputed to dig out planted grains in croplands. Also knocks down surface workings of termites (Isoptera) in order to eat termite workers. Takes fruit from dwarf shrubs. Not known to visit watering points to drink.
Breeding. Season varies geographically: breeds after winter rains in SW, eggs Sept-Oct; later, in Nov-Dec, in C Karoo, and even later, Feb-Apr, in C Namibia, in association with late-summer rains (delayed onset of breeding in N mirrored by later post-breeding moult). Male aerial display close to ground, then rising and falling vertically 10-15 m on closed wings, calling at peak of ascent. Monogamous, mostly in pairs throughout year. Nest, reported by some as built by male alone, an open cup, usually at base of a bush, rock or grass tuft, generally without domed roof, although in at least one instance a suggestion of a dome fashioned from overhanging vegetation. Clutch usually 2 eggs, sometimes 3; incubation period unknown; nestlings fed by both parents, fledging period not known; after leaving nest young remain with parents, are fed by them for several weeks.
Movements. Apparently resident. Counts in S Karoo revealed erratic fluctuations in population density, but unclear whether these are real or are artefacts of sampling method.
Status and Conservation. Not globally threatened. Common to very common in most of range; widely distributed in W interior of S Africa. Particularly numerous in C Karoo, where it reaches the highest densities attained by any member of the "*C. curvirostris* complex"; in S Karoo shrublands, attains densities of up to 10 birds/km². Sometimes considered to be a pest in croplands, where alleged to dig out and consume planted grains. Despite its relative abundance, little is known about its breeding biology.

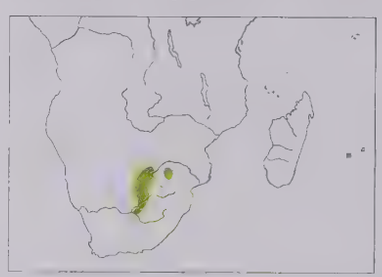
47. Benguela Long-billed Lark

Certhilauda benguelensis

French: Alouette de Benguela **Spanish**: Alondra de Benguela
German: Benguela-Langschnabellerche

Taxonomy. *Alaemon benguelensis* Sharpe, 1904, Benguela, Angola.
All members of genus with exception of *C. chuana* formerly treated as a single species, but recent research indicates that they are genetically, morphologically and vocally distinct. Present species very similar in morphology and vocalizations to N population of *C. subcoronata*, but genetically highly distinct; treated as a separate species, pending further study. Position of taxon *damarensis* somewhat unclear; possibly belongs with present species, but analysis of plumage and morphology suggests better placed with *C. subcoronata*; limited genetic sampling in Namibia of *damarensis* and race *kaokoensis* of present species resulted in uncertainty regarding the taxonomic boundary between them. Two subspecies recognized.
Subspecies and Distribution.
C. b. benguelensis (Sharpe, 1904) - SW Angola and extreme NW Namibia.
C. b. kaokoensis Bradfield, 1944 - NW Namibia S to about Brandberg.



Descriptive notes. 18-20 cm (male on average 12-14% larger in body measurements, 28% longer in bill); 35-53 g. Medium-sized lark with rather pale and only moderately streaked plumage, narrow pale supercilium and eyering. Is more or less grey-brown above, streaked darker; whitish below, breast with dark brownish spots and streaks; eyes dark brown; bill blackish-horn; legs dull pinkish-brown. Sexes alike in plumage. Juvenile has buff-white feather tips above, breast more diffusely spotted. Race *kaokoensis* is smaller and perhaps paler above than nominate. Voice. Male song a slightly quavering, descending whistle, "peeooo", like that of congeners but with perhaps less change in pitch. Also burry contact calls.
Habitat. Arid stony hill slopes and adjacent plains in the fore-Namib; often favours areas with slightly denser scrub.
Food and Feeding. Very little known. Diet includes beetles (Coleoptera) and other insects, and also seeds.
Breeding. Few records, all of nests found in late May: built in shallow cup on ground, usually at base of a rock, grass tuft or small bush; contained 2-3 chicks. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Locally common in suitable habitat. One of the most common terrestrial bird species on arid coastal plain of SW Angola. Significant populations are conserved in formally protected areas.
Bibliography. Dean (2000), Harrison *et al.* (1997), Keith *et al.* (1992), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Ryan & Bloomer (1999), Sinclair & Ryan (2003).

48. Short-clawed Lark

Certhilauda chuana

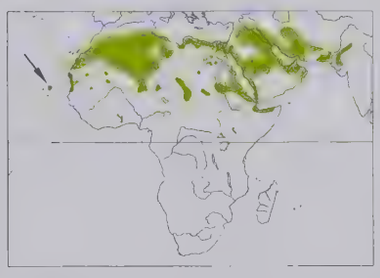
French: Alouette à ongles courts **Spanish**: Alondra Chuana
German: Akazien-Langschnabellerche
Other common names: Short-clawed Bushlark

Taxonomy. *Alauda chuana* A. Smith, 1836, north of Latakoo, Northern Cape, South Africa.
Closely related to the "*C. curvirostris* complex". Monotypic.
Distribution. SE Botswana and South Africa (adjacent Northwest and Limpopo Provinces, in latter including isolated population on Polokwane Plateau).

Descriptive notes. 17-19 cm; 44 g (male appreciably larger than female). Fairly large, slender lark with prominent pale creamy supercilium, boldly spangled upperparts. Feathers of crown and upperparts are dark blackish-brown with broad buff margins, hindneck paler; throat whitish, rest of underparts pale creamy buff, richer on breast, and variably streaked darker brown on breast; eyes brown; bill dark horn-brown; legs dull pinkish-brown. Distinguished from other members of genus by boldly marked upperparts. More slender and elongate than *Mirafra africanica*, lacking rufous wing panel and rufous crest. Sexes alike, but smaller female much less obtrusive. Juvenile has upperpart feathers tipped white, diffuse spots on breast. Voice. Male song, in aerial display or from perch, a single ascending whistle, "pooooeeee"; also gives series of 1-3 loud, simple whistles, usually descending in pitch, "wheoo wheooo". Variety of burry and harsher contact calls.
Habitat. Rather arid acacia (*Acacia*) savanna on granitic soils; avoids Kalahari sands. Found in areas with fairly short, sparse grass cover and short (2-3 m) scattered acacias; prefers recently fallow land with small *A. tortillis* saplings and heavily grazed areas; absent where less grazing and taller, denser grass cover. On other hand, disappears from areas if excessive grazing results in increased tree and shrub cover (bush encroachment). Occurs in semi-arid *Tarchonanthus* savanna, but at lower densities, in SW of range.
Food and Feeding. Diet includes variety of insects, e.g. grasshoppers (Acrididae), beetles (Coleoptera), caterpillars, termites (Isoptera) and ants, also seeds; chicks fed with insects and other invertebrates. Forages on ground. Most prey located visually, but occasionally uses bill to dig for

items in softer soils. Also gleans insects from low vegetation, and even reported to obtain them by shaking plant stems.
Breeding. Laying Sept-Mar (mostly Oct-Dec), associated with start of summer rains; usually two broods, sometimes more. Monogamous, but some females disperse after breeding, and take new partners in following season; territorial, male defends territory of 2-20 ha. Displaying male flies low, parallel to ground, then swoops straight up for 8-12 m, closing wings while still climbing, whistles at peak, stalls and falls back earthwards, opening wings again just before reaching ground, behaviour very like that of congeners; courts female by strutting around her with tail vertical, or hovering next to her, occasionally presents food to her. Nest built by female, often accompanied by male while collecting material, taking 5-14 days, an open cup placed at base of a grass tuft or shrub, usually on S side of such sheltering vegetation, presumably to maximize amount of shade. Clutch 2-3 eggs (typically 3 in Botswana, 2 in Polokwane area of South Africa), rarely 1, replacement laid if clutch lost; incubation by female only, period 16 days; chicks brooded by female, which often shades them from sun in hot weather, fed by both sexes; young leave nest at c. 11 days, before able to fly, can fly strongly by day 18, fed for at least 1 month, mostly by male; female may start construction of new nest within 1 day of chicks leaving nest, and lay within a week of the last brood fledging. Breeding success in Polokwane Nature Reserve high: 15 chicks fledged from 24 eggs in 12 nests (62%), and in one season one pair made five breeding attempts, three successful (raising six chicks); causes of failure include trampling and apparent predation of eggs, and one chick drowned in severe thunderstorm.
Movements. Resident. Constant dialectal differences in voice in SE Botswana suggest limited dispersal; colour-ringed males, however, could not be relocated more than 2 months after ringing, suggesting considerable turnover in territories.
Status and Conservation. Not globally threatened. Common in Botswana; scarce in South Africa, where classified as "Near-threatened" in Red Data list for that country. Total population estimated at more than 10,000 individuals; possibly this many in SE Botswana alone, where displaying males occur at densities of more than 1/ha. Only 130-300 individuals, however, occur in protected areas. Susceptible to changes in agricultural practices that could cause bush encroachment.

Barnes (2000), Brooke (1984b), Collar & Stuart (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Engelbrecht (2004), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Herremans (1997), Herremans & Herremans (1992), Herremans *et al.* (1994), Hunter (1990, 1991), Hustler (1985), Keith *et al.* (1992), Mackworth-Praed & Grant (1962), Maclean (1993a), Newman (1991), Penry (1994), Robertson (1991), Ryan & Bloomer (1999), Sinclair & Hockey (1996), Tarboton (2001), White (1956), Wilson, J.R. (1984).



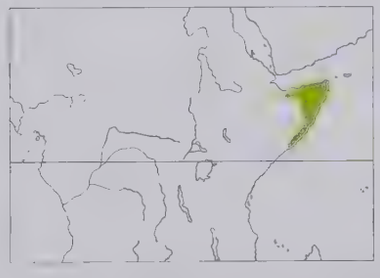
Genus *ALAEMON* Keyserling & J. H. Blasius, 1840

49. **Greater Hoopoe-lark**

Alaemon alaudipes

French: Sirli du désert **German**: Wüstenläuferlerche **Spanish**: Alondra Ibis
Other common names: Hoopoe Lark, Bifasciated Lark, Large Desert Lark

Taxonomy. *Upupa alaudipes* Desfontaines, 1789, between Gafsa and Tozeur, Tunisia.
Affinities uncertain. May form a superspecies with *A. hamertoni*, but differs from that species in nest and display behaviour. Geographical variation rather slight; size increase partially clinal from W to E. Nominate race and *doriae* intergrade in Middle East. Four subspecies recognized.
Subspecies and Distribution.
A. a. boavistae Hartert, 1917 - Cape Verde Is (Boavista, Maio).
A. a. alaudipes (Desfontaines, 1789) - Sahara Desert (from S Morocco S to Mauritania, N & C Mali, C Niger, C & E Chad and N Sudan) E to Syria, Jordan and N Arabia.
A. a. desertorum (Stanley, 1814) - Red Sea coasts from S Sudan (Port Sudan) S to NW Somalia, and from C Saudi Arabia (Jiddah) S to S Yemen (Aden).
A. a. doriae (Salvadori, 1868) - Iraq and E Arabia E to Pakistan and adjacent extreme NW India.



Descriptive notes. 19-23 cm, including bill c. 3-3·5 cm; male 39-47 g (*alaudipes*), 47-51 g (*doriae*), female 30-39 g (*alaudipes*), 46-47 g (*doriae*). Rather large, slim, elongated, long-legged lark with long, thin and decurved bill with very pointed mandibles; long and broad wings, rather long tail; hind claw short (6·2-8·6 mm) and slightly curved. Nominate race has well-marked head pattern, with creamy supercilium, long and narrow dark eyestripe, blackish moustachial stripe; sandy or buffy brown above, grey areas in centre of forehead, central crown, nape and side of head; primaries black with white bases, tipped white (except outers), secondaries white with broad black central band (black-and-white wing pattern striking in flight), long outer primary (extends 1-9 mm beyond primary-covert tips); tail blackish, central rectrices brown with broad paler buffy edges, outer rectrices mainly white; breast cream, blotched with small blackish spots, rest of underparts creamy white; eyes dark brown; bill dark grey; legs and feet pale grey. Rarer grey morph has upperparts uniformly grey; intermediates also occur. Sexes similar. Juvenile is like adult, but head pattern less well marked, upperpart feathers broadly fringed and tipped buffy, outer primary even longer (c. 9-11 mm beyond tips of primary coverts); post-juvenile moult incomplete in late-fledged birds, some retain juvenile feathers in primaries, greater primary coverts and tail. Races differ mainly in size and plumage colour: *boavistae* is smaller, browner and darker than nominate; *desertorum* is as small as previous, greyer; *doriae* is also very grey, small, but larger in W (Iran) than in E (Pakistan, NW India). Voice. Very characteristic song, given in acrobatic flight display, a series of uniform, melodious and rather melancholic piping sounds, starts slowly and accelerates as bird climbs, then a short trill at peak of ascent, then a further series of fluting whistles dropping in speed and tone; song lasts c. 12 seconds, may be repeated after only 5 seconds. Also short, buzzing "zee" or "zrrree" as contact call.
Habitat. Desert or semi-desert, in open plains or rolling terrain, with sandy soils and sparse vegetation cover; also in areas with mixture of gravel and sandy soils. In N Africa highest densities on coastal or sublittoral *regs* (gravel plains with mixed sandy areas) with *Nucularia* bushes and heaps of wind-blown sand. Vegetation height very variable; presence of sand or soft and bare ground appears to be essential. Usually in lowland areas, but to 2000 m in Pakistan.
Food and Feeding. Chiefly invertebrates, some small vertebrates; also some seeds and green material. Main invertebrate groups taken differ regionally, usually dominated by beetle (Coleoptera) larvae, grasshoppers (Acrididae), termites (Isoptera), ant-lion (Myrmeleonidae) larvae, and snails. Small geckos (Gekkonidae) and other lizards also eaten. Normally found singly or in pairs, although small parties have been observed. Digs in sand or soft soil, to depth of 5 cm; when sand patchily distributed, as in heaps around bushes, often flies or runs to it, then walks slowly, stops, and digs purposefully to extract prey. Snails carried into air, then dropped on to hard surface (e.g. a stone) to break the shell; shells also broken by being hammered against stone. Does not require drinking water.
Breeding. Season geographically variable, related to rainfall patterns; Oct-Mar in Cape Verde Is; Feb-Jul, but also Oct (after exceptional rainfall), in N Africa and Saudi Arabia; Mar-Jul, possibly to Sept, in Pakistan and India; one or two broods per season. Territorial; territory size more than 1 km² in Israel. Male song flight highly aerobatic, usually takes off from top of bush, with fluttering wings and spread tail, climbs steeply to c. 2-5 m, twists over, often somersaulting, and dives back to same perch, opening wings just before landing. Nest built by female, from small twigs, lined with soft material, internal diameter 7-8 cm, placed on top of small shrub or grass tussock, more rarely on ground and then sheltered by a tussock or rock; when on ground, is rimmed with stones. Clutch 2-4 eggs (mode 2); incubation by female alone or by both sexes, beginning with last or penultimate egg, period 14 days; nestling period 12-13 days; young remain with parents for at least 1 month. Breeding success determined by rainfall; in Saudi Arabia, only some pairs show nest-building activity and no young reared during dry years, whereas large numbers breed successfully in good rainfall years; annual adult survival rate nearly 60%, higher for males (65%) than for females (34%).
Movements. Usually sedentary; territorial throughout year. Some individuals leave territories in dry years, and erratic movements recorded in N Africa. Recorded as accidental in Canary Is, Senegal, Italy, Malta (often), Greece, Turkey and Lebanon.
Status and Conservation. Not globally threatened. Common and widespread in most countries within its extensive range, as in Cape Verde Is, much of N Africa and Middle East, parts of Saudi Arabia, coastal N Yemen, United Arab Emirates, Oman, Iraq and Kuwait, although very low densities usually reported for large desert interior areas. Present in mountain areas of C Sahara, also in very low densities; frequent in littoral and sublittoral Libya. Fairly scarce in Israel, 100-150 pairs estimated in 1980s, declining; scarce in Pakistan; patchily distributed although locally fairly common in NW India. May have expanded locally in N Algeria and also, perhaps as a result of desertification, in EC Chad. Recorded breeding densities of 0·01 birds/ha in Algeria and 0·04-0·05 birds/ha in suitable habitats in C Arabia.
Bibliography. Ali & Ripley (1987), Allouse (1953), Archer & Godman (1937-1961), Aspinall (1996), Bannerman (1953), Bannerman & Bannerman (1968), Blondel (1962), Borrow & Demey (2001), Brooks, D.J. *et al.* (1987), Brosset (1956, 1961), Browne (1981), Bundy (1976), Bundy & Warr (1980), Butler (1905), Cave & Macdonald (1955), Clapham (1964), Clarke (1980), Cornwallis & Porter (1982), Cowan & Brown (2001), Cramp (1988), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dupuy (1969), Érard & Étchécopar (1970), Étchécopar & Hüe (1964), Gallagher & Woodcock (1980), Giraudoux *et al.* (1988), Goodman *et al.* (1989), Grimmett *et al.* (1998), Hazevoet (1995), van Heezik & Seddon (1999), Hegazi (1981), Heim de Balsac (1936), Heim de Balsac & Mayaud (1962), Henry & Gazave (1998), Hextell (1999), Hollom *et al.* (1988), Hüe & Étchécopar (1970), Inbar (1982), Isenmann & Moali (2000), Jennings (1980b, 1981), Keith *et al.* (1992), Kittenberger (1959), Ledant *et al.* (1981), Lees-Smith (1986), Lunais (1984), Mackworth-Praed & Grant (1960, 1970), Marchant (1963), Martín & Lorenzo (2001), Mayaud (1985), Meinertzhagen (1951, 1954a), Moore & Boswell (1956), Morel & Morel (1990), Morel & Ndao (1978), de Naurois (1989), Newby (1980), Newton & Newton (1997), Niethammer (1955b, 1963b), Nikolaus (1987), Paludan (1959), Ramadan-Jaradi & Ramadan-Jaradi (1999), Richardson (1990), Rietkerk & Wacher (1996), Ripley (1982), Roberts (1992), Salvan (1968), Schönwetter (1979), Shelton (1997), Shirihai (1996), Shobrak (1998), Simon (1965), Smith (1965), Snow & Perrins (1998), Sultana & Gauci (1982), Svensson *et al.* (1999), Thévenot *et al.* (2003), Thomsen & Jacobsen (1979), Tieleman (2002), Tieleman & Williams (2002a, 2002b), Tieleman, Williams & Buschur (2002), Tieleman, Williams, Buschur & Brown (2003), Valverde (1957), Vaurie (1959), Walker (1981b), Wallace (1983, 1984), Welch & Welch (1984), White (1957b, 1961a), Williams & Tieleman (2000), Williams *et al.* (1999).

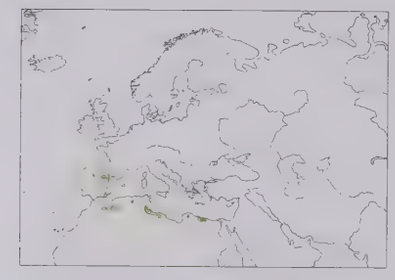
50. **Lesser Hoopoe-lark**

Alaemon hamertoni

French: Sirli de Witherby **German**: Somaliläuferlerche **Spanish**: Alondra de Hamerton
Other common names: Witherby's Lark

Taxonomy. *Alaemon hamertoni* Witherby, 1905, Obbia, Somalia.
Affinities uncertain in absence of genetic data. May form a superspecies with *A. alaudipes*; differs, however, from that species in nest and display behaviour. Possible link with *Certhilauda* proposed by some authors. Geographical variation limited, and possibly clinal; racial identity of birds in NE corner of Somalia not known, tentatively placed with *altera* but further study needed. Three subspecies recognized.
Subspecies and Distribution.
A. h. tertia S. R. Clarke, 1919 - inland in NW Somalia.
A. h. altera Witherby, 1905 - N & NE Somalia.
A. h. hamertoni Witherby, 1905 - coast of C Somalia, extending inland to Ethiopian border in N.

Descriptive notes. 17-21 cm. Large, slender lark with uniform plumage, long bill and legs. Has plain face apart from faint paler supercilium; virtually plain above, pale grey-brown, with slightly darker brown flight-feathers; underparts whitish or buffy, breast with indistinct mottling; eyes dark brown; bill horn; legs whitish. Differs from *A. alaudipes* in smaller size, plain face and wings, lacking black-and-white wing pattern; distinguished from *Mirafra somalica* (which has almost identical geographical range) by always plainer and generally paler plumage. Sexes alike in plumage, female on average smaller than male. Juvenile unknown. Races differ in upperpart coloration: *tertia* is more rufous tawny-sand than nominate; *altera* is paler and warmer sandy brown. Voice. Undescribed.
Habitat. Open grassland, favouring tussock grass; generally avoids areas with any shrubs or trees. No known range overlap with *A. alaudipes*.
Food and Feeding. Diet likely to consist largely of insects. Feeds on ground, running rapidly and covering large distances. Behaviour and gait like those of a pipit (*Anthus*). Uses the bill to dig vigorously in soft sand for insect larvae. Frequently perches on top of grass tufts.



Breeding. Recorded in May-Jun. Probably monogamous; usually observed in pairs. Has distinctive display-flight, parachuting back to ground on open wings from considerable height. Two nests found, each an open cup lined with fibrous grass stems, in shallow depression in loose, sandy soil, one at base of a grass tuft, the other in the open and sheltered only by few short stems. Clutch 2-3 eggs; parental duties and incubation and fledging periods unknown.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Common to locally common. Poorly known species.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Clancey (1986b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Mackworth-Praed & Grant (1960).

Genus *CHERSOPHILUS* Sharpe, 1890

51. Dupont's Lark
Chersophilus duponti

French: Sirli de Dupont **German**: Dupontlerche **Spanish**: Alondra Ricotí

Taxonomy. *Alauda Duponti* Vieillot, 1820, Provence, south France.
Relationships uncertain. Races well differentiated; populations from Morocco E to N Tunisia, however, somewhat intermediate in colour between nominate and *margaritae*, and locally rather variable. Two subspecies recognized.
Subspecies and Distribution.
C. d. duponti (Vieillot, 1820) - Spain (mainly E Castilla y León and Aragón, also W Castilla y León near Portuguese border, E Castilla-La Mancha and SE Andalucía), Morocco (mostly in NE, E of Midelt and R Moulouya, also some recent records from S of Great Atlas) and N Algeria (Hauts Plateaux).
C. d. margaritae (Koenig, 1888) - Algeria (S slopes of Atlas Mts E to Biskra), SE Tunisia, N Libya and coastal W Egypt.

Descriptive notes. 17-18 cm; c. 32-47 g. Medium sized, densely streaked, relatively long-legged lark with long neck, long slender bill with distal half decurved, rather short wings, short tail; toes and claws short and thick, but hind claw long (8-12·5 mm) and straight. Nominate race has thin pale median crown-stripe, buff-white supercilium and eyering, thin dark malar stripe; brown above, densely streaked, feathers of mantle and scapulars with narrow pale fringes; wings with reduced outer primary (4-11 mm short of tips of primary coverts); underparts whitish, breast prominently streaked dark brown; eyes dark brown; bill flesh-coloured with darker culmen, lower mandible paler; legs flesh-brown. Differs from rather similar *Alauda arvensis* in slimmer build, with long neck and long, curved bill. Sexes similar. Juvenile is like adult, but upperpart feathers with broader scaly fringes and white tips, outer primary longer (about equal to longest covert) and broader. Race *margaritae* is much paler and cinnamon reddish, less prominently streaked, has longer bill, shorter hind claw. Voice. Male song, from ground or in flight, mostly at dawn and sunset, a mix of twittering with buzzing notes, like Eurasian Linnet (*Carduelis cannabina*) song, often lasting up to 30 minutes or more. Most common call a very characteristic, ventriloquial, human-like whistle, "hoo hee" or "pu chee", second note rather nasal and drawn out, usually given from ground behind concealing vegetation, sometimes in flight; alarm a shrill "tsii".

Habitat. Open plains with shrub-steppe or feather-grass (*Stipa*) steppe, on flat or rolling terrain. In Spain, shrubs mainly 40-60 cm tall, and medium-high percentage of bare ground; altitudinal range 50-1550 m, most at 1000-1400 m. In N Africa, *Stipa tenacissima* steppes apparently preferred to wormwood (*Artemisia*) shrubs; at 600-1200 m. Also found in cereal fields outside breeding season.
Food and Feeding. Diet insects and seeds. Few details on adult diet, restricted to Spain; few stomachs analysed contained beetles (of families Carabidae, Tenebrionidae, Scarabaeidae, Silphidae, Curculionidae), grasshoppers (Acrididae) and ants, also seeds (mainly of *Asphodelus*); also observed to dig for beetle larvae (probably Tenebrionidae and Elateridae) in spring. Nestlings fed only with invertebrates, mainly spiders, grasshoppers and caterpillars, 6-12 mm in size. Feeding behaviour little known; forages mainly by digging; has been observed to catch spiders (of family Lycosidae) in their holes, and to dig in dung. Apparently does not drink water.
Breeding. Mar-Jul; song from Jan-Feb, pairing in Spain in Mar; often more than one brood. Probably semi-colonial; territorial. Song-flighting male rises to often considerable height (100-150 m), remains aloft, singing continuously, for 30 minutes or more, suddenly descends rapidly and vertically to ground; wing-clapping recorded during song flights at lower levels. Nest a scrape on ground, beside small shrub or tuft or in open, lined with twiglets, vegetable fibres and hair, orientation mainly in NE-NW quarter. Clutch 3-4 eggs (mode 3) in Algeria and Tunisia, 3-5 (mode 4) in Spain; replacement clutch laid if previous one lost; incubation period 12-13 days; hatching of last chick, often also penultimate one, asynchronous; chicks tended and fed by both parents, nestling period 8 days, probably longer if nest not disturbed; period of juvenile dependence unknown. Nestling mortality in Spain very high, up to 84%, in some cases mainly through predation by snakes and foxes. Longevity at least 4 years.
Movements. Resident; probably irregular movements during winter. In Spain, has been observed in winter flocks with other lark species, on extensive cereal cultivations; winter records in N Africa outside known breeding areas. Vagrants recorded E & N to Italy, Malta, Greece (Crete) and Cyprus.
Status and Conservation. Not globally threatened. Sparsely distributed and uncommon in most areas. Range relatively small and fragmented; still imperfectly known owing to the species' secretive habits. In Morocco, common during early 1960s in Hauts Plateaux, extending up upper Moulouya Valley; also scattered sightings S of High Atlas Mts (between Ouarzazate and Taroudant and in Boumalne du Dadès area). Nowhere common in Algeria, where most records in NW, towards Moroccan border; in 1935-1937 bred commonly in Tebessa, near Tunisian border. Probably rare and local in Tunisia, occurring at scattered sites from Feriana region S (through Gafsa, Kebili, Matmata and Tatahouine) to Libya; rarely seen in recent times. In Libya, thinly distributed in Tripolitania and scarce and local in Cyrenaica (Jabel al Akhdar E to Al Adam). Scarce along coast of Egypt (Salum E to Bahig), breeding reported in 1994. In Spain, where breeding status was long overlooked, total area occupied calculated at c. 500 km^2 and population in 1988 at c. 13,000 individuals (although recent work suggests that numbers greatly overestimated owing to inaccurate methodology); 68% of population in high-altitude areas of Iberian System and nearby zones of N Meseta provinces of Guadalajara, Soria and Segovia (0·2-0·4 pairs/ha calculated in Soria), 28% in shrub-steppes of middle Ebro Valley (Huesca, Zaragoza and Teruel), and remainder scattered in small isolated nuclei in other areas of N Meseta (Zamora), S Meseta (Cuenca, Albacete), Murcia region and SE Andalucía (Granada, Almería). Probable former breeding elsewhere in Europe indicated by 19th-century records from Portugal (near Lisbon) and S France (mostly from Crau, where last recorded in 1915). Recently included in "Endangered" category in Spanish Red Data Book on basis of small population size and apparently rapid decline; threatened by habitat loss through reafforestation schemes, agricultural expansion and, perhaps, inappropiate sheep-stock levels leading to either overgrown or overgrazed vegetation; proposed construction of airport at Lleida could exterminate the sole surviving population in Catalonia.

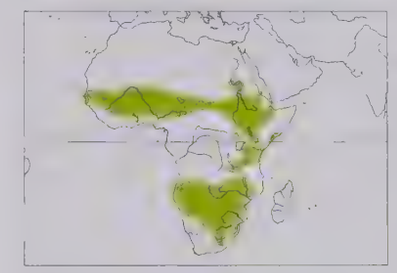
Genus *EREMOPTERIX* Kaup, 1836

52. Black-eared Sparrow-lark

Eremopterix australis

French: Moinelette à oreillons noirs **Spanish**: Terrera Orejinegra
German: Schwarzwangenlerche
Other common names: Black-eared Finch-lark, Grey-backed Sparrow-lark(!)

Taxonomy. *Megalotis australis* A. Smith, 1836, Colesberg, Orange River, Northern Cape, South Africa. Typically considered to be an outlier within *Eremopterix*, because of its unusual plumage; whether this reflects a basal position within the genus is unclear. Monotypic.
Distribution. S Namibia (S from N Namaqualand), extreme SW Botswana (Kalahari-Gemsbok National Park) and W half of South Africa (Great Karoo).



Descriptive notes. 12-13 cm; 12-16 g. Small, sexually dimorphic lark resembling a finch (Fringillidae). Adult male is highly distinctive; has black head, neck and underparts; rest of upperparts chestnut with darker feather centres, wing-coverts and tertials blackish with broad chestnut fringes; flight-feathers dark blackish-brown; black underwing, which is distinctive in flight; eyes brown-red; bill bluish-white to pale steel-grey; legs greyish-white to dull flesh. Female is warm brown, streaked darker brown, above, tertials and wing-coverts with broad rufous fringes, face mottled brown with rather weak, pale supercilium, underparts whitish with quite dense dark streaks becoming thinner and fainter towards belly and flanks, underwing-coverts and most of underside of secondaries blackish, bill pale straw to whitish-flesh with darker, greyer culmen, legs pale pinkish-flesh; lacks dark belly patch of females of other members of genus, and differs from *E. leucotis* in having uniform rump and back, from *E. verticalis* in darker brown coloration above, from both in having more extensive black on underwing. Juvenile resembles female, but upperpart feathers have pale tips and dark subterminal bars, giving more spotted or scaly appearance, breast streaks more diffuse, appearing mottled; immature male plumage (acquired in post-juvenile moult, several months after fledging) similar to female, but with variable amount of black feathering on face and breast, adult plumage acquired after first complete moult at c. 1 year old. Voice. Male song a short twitter, given mostly from ground; usual song in aerial display a simple series of buzzy notes. Chorus of calls from flushed flock deeper and less sharp than that of *E. verticalis*. Greeting call a trilled "preee"; alarm a sharp "dreee"; distress call of male a soft "tik-tik-tik", of female a raspy "chee-chee-chee". Adult feeding call to chicks a soft "preep".
Habitat. Shrubland and grassland, often in association with *Rhigozum* shrub patches, in the Karoo and S Kalahari. Largely confined to red sands in the Kalahari and W Namaqualand, but common on clays and stony soils in the Karoo. Often found in areas of denser vegetation along shallow drainage lines, but avoids riparian systems with acacias (*Acacia*); appears to prefer taller and denser vegetation than that inhabited by *E. verticalis*.
Food and Feeding. Primarily grass seeds, but also some forbs and *Lycium* fruits; also insects, including termites (Isoptera), beetles (Coleoptera), ants, bugs (Homoptera). Forages on the ground, in bare areas among denser vegetation, usually in flocks; typically shuffles along in crouched posture, but stands erect when alarmed. Picks food items from ground or directly from plants. Very seldom drinks water.
Breeding. Nesting recorded in all months; breeds opportunistically after rain, requires at least 40 mm of rain to stimulate widespread breeding; in N & NW Karoo, abundance of *Stipagrostis* awns, used for lining nest, may be indicator of suitable breeding conditions. Monogamous. Nests singly, normally in small pockets with conspecifics (sometimes within 20 m of another pair) alongside large numbers of other nomadic seed-eaters, notably *E. verticalis*, *Spizocorys starki* and Lark-like Bunting (*Emberiza impetuani*). Male butterfly-like display-flight 5-15 m above ground, with deep, exaggerated wingbeats showing off black underwings, then lands, with head erect and tail cocked, next to female; displaying may occur for several weeks before nesting commences, although interval between rains and breeding shorter in austral summer (1-3 weeks) than in winter (up to 11 weeks), linked to lag in seed-set by grasses. Nest built by female, taking 4-5 days, in shallow scrape in ground against base of a bush (normally on E or SE side, where shaded from afternoon sun, although often in the open in winter months), foundation of sticks, lined with fine grass leaves and awns, rim characteristically decorated with dry twigs and sand-encrusted webs of *Seothyra* spiders, the webs occasionally delivered by male but placed in position by female. Clutch 2-3 eggs, rarely 1 or 4 (mean 2·5), laid at 1-day intervals, clutch size increases with increasing rainfall; incubation usually from first egg, both sexes contributing roughly equal effort during day; male often alerts sitting partner to danger by flying over territory, then diving down over nest; incubation period 8-12 days (average 10·2 days); newly hatched chicks brooded and fed by both parents, male more time than female; when nest approached, both sexes may attempt to lure intruder away by fluttering along ground and calling (feigning injury), male also has low aerial display, with exaggerated wingbeats or occasionally loud wing-snaps, which may also serve to distract intruders; chicks leave nest, typically at instigation of female, after 6-11 days, usually 9 days, before able to fly, initially crouch when threatened but within few days can run rapidly; able to fly after 15-20 days. Breeding success generally low owing to high rate of nest predation, primarily by small mammalian predators such as mongooses (Herpestidae); most losses occur during egg stage, only 50% of clutches survive to due hatch day, 87% of eggs reaching that date hatch, and 74% of broods survive to fledging; overall breeding success 31%, with 0·86 young fledged per attempt, and in the Kalahari only 25% of nests successful; clutch size had no impact on risk of nest predation; in one case, a chick killed and eaten and another badly injured by a large spider (burrow of which opened into the nest-chamber); heavy rain can also cause severe chick mortality, with 77 mm of rain over 2 days killing 43% of chicks. Maturity usually at 1 year; some males breed in immature plumage.
Movements. Nomadic, moving in response to rainfall events. Occurrence, however, quite predictable in certain areas (e.g. Tankwa Karoo), despite limited rainfall; atlas-survey records suggest general movement S in summer months, perhaps to avoid excessive heat in S Kalahari.
Status and Conservation. Not globally threatened. Common, even locally abundant when conditions favourable. Most abundant in Nama Karoo and on Namaqualand coastal plain; patchily distributed in S & C Karoo; generally less common in Namibia and Botswana. Average flock size in the Karoo 40 birds, but highly variable, and flocks not very cohesive. Historical breeding records from the former Transvaal (where last recorded 1870) suggest possible range contraction. The species' core range is poorly represented in formal conservation areas. In view of its wide-ranging nomadic behaviour and apparent preference for taller, denser vegetation, which makes it perhaps the most susceptible of the Karoo nomadic seed-eaters to poor grazing practices, its status should be monitored.
Bibliography. Cooper & Donnelly (1983), Dean (1997), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), Lloyd (1998, 1999, 2004), Lloyd *et al.* (2000), Mackworth-Praed & Grant (1962), Maclean (1970a, 1970b, 1993a), Sinclair & Hockey (1996), Sinclair & Ryan (2003), Tarboton (2001).

53. Chestnut-backed Sparrow-lark

Eremopterix leucotis

French: Moinelette à oreillons blancs **Spanish**: Terrera Orejiblanca
German: Weißwangenlerche
Other common names: Chestnut-backed Finch-lark, White-cheeked Sparrow-lark/Finch-lark

Taxonomy. *Loxia leucotis* Stanley, 1814, coast of Eritrea.
Relationships uncertain; has been considered to form a superspecies with *E. nigriceps* on basis of male plumage patterns. Five subspecies recognized.
Subspecies and Distribution.
E. l. melanocephalus (M. H. K. Lichtenstein, 1823) - Senegal E to C Sudan.
E. l. leucotis (Stanley, 1814) - SE Sudan, Ethiopia, Eritrea and NW Somalia.
E. l. madaraszi (Reichenow, 1902) - NE Uganda, Kenya, coastal S Somalia, Tanzania and N Mozambique.
E. l. hoeschi C. M. N. White, 1959 - S Angola, W Zambia, N Namibia, N Botswana and NW Zimbabwe.
E. l. smithi (Bonaparte, 1850) - E Zambia, S Malawi, W & C Mozambique, E Zimbabwe, E Botswana and E South Africa.

Descriptive notes. 12-14 cm; 12-21 g. Small, sexually dimorphic lark with appearance like that of a finch (Fringillidae). Adult male nominate race has head mostly black, with large white ear-covert patch and variable white nape; upperparts rich chestnut, rump and uppertail-coverts paler greyish-buff; wing-coverts mostly chestnut, outer lesser coverts whitish, median coverts blackish; flight-feathers brown, broad chestnut margins of secondaries and tertials; tail brown, central feathers broadly edged chestnut, outer feathers edged whitish; mostly black below, variable whitish rear flanks and vent, underwing-coverts blackish (prominent in flight); eyes brown; bill whitish; legs pale flesh-grey. Distinguished from all congeners by combination of fully black crown, white ear patch and rich chestnut upperparts. Female is duller than male, has brown crown and grey-brown ear-coverts, duller chestnut upperparts streaked dark brown and with narrow pale margins, variable whitish collar, creamy-buff underparts with variable dark brown streaks on breast and throat, blackish-brown central belly (often extending up central breast to throat), slightly duller horn-coloured bill; differs from females of most congeners in chestnut upperparts with contrasting paler rump, from *E. australis* by blackish belly patch and less extensive black on underwing, from *E. signatus* by more streaked face and no rufous supercilium. Juvenile resembles female, but has white fringes on crown and back feathers; plumage retained for only a few weeks or months, male moults into mottled immature plumage. Races vary mostly in plumage colour, also size (larger in S): *madaraszi* male is redder-tinged above, bill larger, female duller with throat to belly blackish; *hoeschi* male is more tawny above, female paler and greyer with pale underparts; *smithi* male resembles previous, female has dull chestnut ground colour above, black patch on lower breast and belly; *melanocephalus* is more distinctive, male brighter and redder above, mostly white outer wing-coverts, female brighter chestnut above, breast pale buff with dark brown mottling, dark brown on central belly. Voice. Male song rather monotonous "shrimp zzt zzt zrit", final note higher-pitched; also gives sweet, high-pitched whistles. Flight call a sharp, high-pitched "chip", typically in chorus by many birds when flock rises.
Habitat. Short, open grassland, and semi-arid savanna. Favours bare ground, burnt areas, fallow fields and recently ploughed lands.
Food and Feeding. Food mostly grass seeds; grasshoppers (Acrididae) and other insects taken primarily when feeding chicks. Usually occurs in small flocks of up to 50 individuals, sometimes among flocks of others of genus, especially *E. signatus*. Feeds on the ground, typically shuffling along in crouched posture. Uses elevated perches, including termitaria, trees and wires, to reduce heat stress. Drinks frequently.
Breeding. Mostly Oct-Mar in N; during dry season, Mar-Sept, in Zambia, Zimbabwe and Malawi; in South Africa often earlier, mostly Mar-Apr (at end of summer rains), although nesting recorded throughout year; some pairs double-brooded. Monogamous. Nests singly or in small groups, with inter-nests distance as little as 3 m. Male performs display-flight, circling 10 m above ground, also displays to female on ground, with drooped wings and raised plumage; pugnacious, chases off other males and even other species. Nest built by both sexes, material added even after eggs laid, an open cup lined with grass and rootlets, in shallow depression usually at base of a small grass tuft; in S most nests are on S to E side of sheltering vegetation, presumably to provide afternoon shade. Clutch 1-2 eggs, rarely 3, varying regionally, usually 1 in W Africa but 2 (mean 1·9) in S Africa, laying interval 1 day; incubation by both sexes, apparently solely by female at night, shifts generally fairly short (maximum 1-3 hours), female when being relieved often solicits food from male, fed by regurgitation; in one case an offspring from the previous

On following pages: 54. Black-crowned Sparrow-lark (*Eremopterix nigriceps*); 55. Grey-backed Sparrow-lark (*Eremopterix verticalis*); 56. Chestnut-headed Sparrow-lark (*Eremopterix signatus*); 57. Fischer's Sparrow-lark (*Eremopterix leucopareia*); 58. Ashy-crowned Sparrow-lark (*Eremopterix griseus*).

brood incubated when female left nest, was fed by latter on her return to resume incubation, then chased off by female when male returned; incubation period 11 days; chicks hatch within hours of each other (suggesting that incubation starts only when clutch complete), eggshell fragments removed by parents, both sexes brood and feed chicks, female probably undertaking greater part of provisioning, chicks fed with regurgitated seeds or single seeds collected close to nest; adults fly over intruders, calling agitatedly; chicks leave nest with only half-grown flight-feathers, follow the foraging female, fledging period 10-12 days. Maturity 1 year; some males breed before attaining adult plumage.

Movements. Mostly nomadic; some populations resident, others perhaps fully migratory. In W Africa, post-breeding movement from N margin of range in the Sahel (where breeding during rains) S into more mesic areas, but other W populations resident. Movements erratic and poorly understood in Kenya; most Tanzanian records are of non-breeding birds moving S in dry season. In S Africa, resident in some areas (e.g. Zambezi Valley, Springbok flats) but nomadic elsewhere; irrupts W into more arid areas during summer rains and E into more mesic areas in dry season, but movements not well understood, with breeding in both wet and dry seasons.

Status and Conservation. Not globally threatened. Fairly common to common throughout much of its range, but scarce and erratic at the periphery. Risk of potential threat from habitat loss minimized by fact that it favours agricultural lands and disturbed areas.

Bibliography. Ash & Miskell (1998), Bannerman (1953), Barlow *et al.* (1997), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Butler (1905), Byaruhanga *et al.* (2001), Chittenden & Batchelor (1977), Clancey (1964b), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Ginn *et al.* (1989), Gore (1990), Grimes (1987), Harrison *et al.* (1997), Irwin (1982), Irwin & Lorber (1983), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1962, 1970), Maclean (1993a), Morel & Morel (1984), Nikolaus (1987), Penry (1994), Salvan (1968), Short *et al.* (1990), Sinclair & Hockey (1996), Stevenson & Fanshawe (2002), Steyn (1964), Tarboton (2001), Vincent (1946), Zimmerman *et al.* (1996).

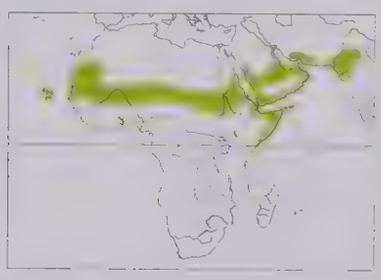
54. Black-crowned Sparrow-lark

Eremopterix nigriceps

French: Moinelette à front blanc **German**: Weißstirnlerche **Spanish**: Terrera Negrita
Other common names: Black-crowned Finch-lark, White-fronted/White-crested Sparrow-lark/Finch-lark

Taxonomy. *Pyrrhalauda* [sic] *nigriceps* Gould, 1839, São Tiago, Cape Verde Islands.

Relationships obscure. Sometimes placed in a superspecies with *E. verticalis*, *E. signatus* and *E. leucopareia*, but has also been considered to form a superspecies with *E. leucotis* on basis of male plumage patterns; alternatively, often regarded as closest to *E. griseus*. Geographical variation largely clinal, size increasing from W to E. Birds from Socotra described as race *forbeswatsoni*, but considered indistinguishable from *melanauchen*. Four subspecies recognized.



Subspecies and Distribution.

E. n. nigriceps (Gould, 1839) - Cape Verde Is.

E. n. albifrons (Sundevall, 1850) - Mauritania and Senegal E to Sudan (E to R Nile).

E. n. melanauchen (Cabanis, 1851) - E Sudan E to extreme S Iraq, Kuwait and C & S Arabian Peninsula, and S to Somalia and Socotra.

E. n. affinis (Blyth, 1867) - SE Iran E to Pakistan and NW India.

Descriptive notes. 10-11 cm; 12-16 g. Small, sexually dimorphic lark resembling a finch (Fringillidae); diagnostic white forehead, rarely absent (one bird from Sudan). Adult male nominate race has distinctive black-and-white head pattern (variable, rarely black replaced by dark brown); upperparts sandy-brown with reddish tinge, paler and greyer in worn plumage (often appearing silvery in harsh desert light); wings darker brown, wing-coverts with pale fringes, median coverts form darker bar on folded wing; tail dark brown, central feather pair with broad pale greyish margins, outer rectrices with narrower whitish edges; chin and entire underparts black, except for white thighs and narrow white stripe down side of breast; underwing-coverts and undertail black, underside of flight-feathers sooty grey-brown; eyes dark brown; bill bluish-white; legs pale flesh. Differs from *E. signatus* in blacker head markings, white forehead, no white crownstripe, much narrower white on breast side; from *E. griseus* in head pattern, less grey upperparts. Female lacks male's distinctive head pattern, is rather nondescript at rest, greyish-rufous above, whitish below, brownish with variable streaking on breast, dark underwing with black underwing-coverts, bill duller horny steel-grey; distinguished from somewhat similar *Eremalauda dunni* and *Ammomanes* and *Calandrella* species mainly by small size, short tail, stubby bill, usually dark median-covert bar, in flight also distinctive dark underwing; from female *E. signatus* by paler coloration, no rufous supercilium or dark belly patch, from female *E. griseus* by sandier general coloration with paler, plainer wings. Juvenile resembles adult female, but with buff margins of contour feathers above, looking slightly scaled; at least some juvenile males moult into intermediate plumage 2-3 months after fledging, others acquire almost complete adult plumage at first moult but typically with cheeks greyer and some paler tips in black breast feathers. Races differ chiefly in extent of male's white forehead patch, also in upperpart colour (but varies individually with degree of wear), and size: *albifrons* is larger than nominate, with more white on forehead, longer wing and tail, female less reddish; *melanauchen* is slightly bigger and greyer than previous, male with smaller white frontal patch, black on lower hindneck; *affinis* is like previous but bigger. Voice. Male song, in aerial display or from low vantage such as bush or rock on ground, considerably variable in structure, typically a short series of simple, sweet, plaintive notes, "tsoo-wee-tsuit", repeated every 1 second; songs similar at a single site, but regional variation over relatively small distances in Yemen. Both sexes also give "tchip" or "cherp" contact call, usually in flight, also softly on ground; also "zree" as alarm, mostly by male, when nestlings approached by intruder. Chicks out of nest frequently call "cheoop".

Habitat. Arid and semi-arid plains with scattered grass and other low-lying vegetation; prefers sandy soils rather than rocky substrates. Also occurs around saline pans.

Food and Feeding. Primarily seeds of grasses and other plants; also insects and other invertebrates, including grasshoppers (Acrididae), beetles (Coleoptera), bugs (Homoptera) and spiders. Chicks fed mainly with insects, including lepidopterans (both adult moths and caterpillars), and other insect larvae. Forages in flocks, usually of 20-50 individuals, occasionally more (to several thousands), when not breeding. Feeds on the ground, stance rather erect compared with that of congeners; takes items from ground surface or from plants, also gleans items from cattle dung; occasionally flutters up to grasp prey out of reach, and will also hawk for insects, showing surprising agility in air. Can be remarkably tame; feeds on spilled grain inside shops in Somalia. Most foraging takes place in early morning and evening. In hot weather seeks shade under bushes, or occasionally in large lizard burrows during heat of day, greatly reducing water loss; loses heat by flying with legs dangling, or by perching with drooped wings, facing into wind, on elevated site. Apparently requires little water, but drinks regularly when water available; tolerates brackish water, observed drinking along seashore and from tidal lagoons in Somalia (albeit in areas where possibly some freshwater seepages).

Breeding. Nesting mostly in association with rainfall, typically in summer in most of range, but also opportunistically, whenever conditions suitable, with records in virtually all months; season short, Apr-Sept, in NE Saudi Arabia (apparently single-brooded); Feb-Sept in Pakistan and India. Monogamous; nests singly or in loose aggregations. Male performs aerial display over territory, rises steeply from ground to 5-10 m, circles while calling for up to 1 minute, then descends in a series of shallow swoops; members of established pair also frequently display together, male chasing female in rapid, twisting low flight; also variety of displays by male to female on ground, including rushing at female with crest raised, head angled down and wings drooped ("charging"), strutting with raised head, vertical tail and drooped wings ("tail-cocking"), approaching female in near-prostrate creeping posture ("sidling"), and apparently less intense form of last with crest raised ("horizontal rigid"). Female apparently selects nest-site, also builds nest, in 2-3 days, shallow depression excavated with the breast, by turning around with wings spread, or natural hollow used where substrate hard, lined with 6-20 large twigs, then with finer grass stems, leaves and awns, also wool, paper and other litter, rim usually decorated with small stones or clods of earth; site typically at base of a grass tuft or shrub, normally on N or E side and thus shaded from hot afternoon sun; in one case, late in season, a pair nested 1 m above ground in hollow under a slab of cement in a pile of rubble, nest barely lined; male, and occasionally female, defend nest-site against other bird species and lizards, as well as conspecifics. Clutch 2-3 eggs, in Somalia occasionally 4, usually 2 in N Africa and India, more frequently 3 (mean 2·6) in NE Saudi Arabia; laying starts 2-3 days after nest completed, laying interval 1 day; incubation apparently from second egg, by both sexes, female doing more (c. 75%), period 11-12 days; in 3-egg clutches, last chick hatches 20-35 hours after other two, is appreciably smaller; chicks brooded and fed by both parents, female doing greater part of brooding, male provisioning more, brooding most intense in hot weather, involves standing over chicks to shade them; feeding mostly in early morning and evening (30% before 08:00 hours, 37% after 16:00); faecal sacs removed by both parents or, rarely, swallowed at nest; male, occasionally also female, distracts intruders by feigning injury or scuttling away from nest; chicks start to leave nest for short periods from day 6, typically leave entirely by day 8, long before able to fly; within a day after nest left, each parent takes sole responsibility for one chick, and chicks separate, possibly to reduce risk of predation; young can run strongly by day 12, flutter weakly by day 14, although wings fully grown only by day 21-22, when tail still barely developed. Breeding success fairly low, c. 20%, with 50% of nests surviving to hatch date and 40% of hatchlings surviving to leave nest (day 8); third egg in 3-egg clutches appears to be for "insurance", as, of six sets of three chicks, only one chick survived to nest departure and that one died within a day (apparently because each parent feeds only a single chick). Maturity normally at 1 year; presumed immature males (in female-like plumage) occasionally recorded as singing and displaying.

Movements. Most populations, even small island ones, subject to some local movements, following favourable conditions; apparently resident in some areas, breeding in same sites in successive years. Some appear to undertake regular migrations, e.g. moves N in summer rainy season to breed in the Sahel (Aug-Oct) and N Arabia (Apr-Sept). Occasionally loose flocks of several thousand individuals in E Saudi Arabia, possibly on migration.

Status and Conservation. Not globally threatened. Locally common throughout much of range. Breeding density up to 1 pair/3 ha in favourable conditions. Desertification in W Africa has led to extension of range to S, resulting in regular occurrence in N Nigeria, where formerly absent. Tolerates moderate levels of grazing pressure.

55. Grey-backed Sparrow-lark

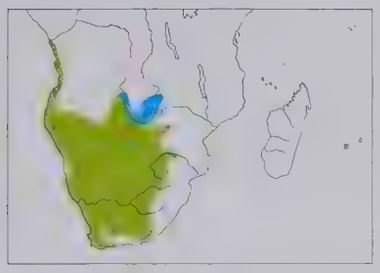
Eremopterix verticalis

French: Moinelette à dos gris **German**: Graurückenlerche **Spanish**: Terrera Dorsigrís
Other common names: Grey-backed Finch-lark

Taxonomy. *Megalotis verticalis* A. Smith, 1836, Colesberg, Orange River, Northern Cape, South Africa.

Relationships uncertain; suggested as forming a superspecies with *E. signatus*, sometimes expanded to include also *E. nigriceps* and *E. leucopareia*. Precise breeding ranges of races inadequately understood; birds breeding in SW Zambia of uncertain racial identity; presumably include *harti*, but all four races recorded in that country. Four subspecies recognized.

Subspecies and Distribution.



E. v. damarensis Roberts, 1931 - coastal Angola (including Cabinda), Namibia, W Botswana and NW South Africa; periodic eruptions E to W Zambia and W Zimbabwe.

E. v. harti Benson & Irwin, 1965 - W Zambia.

E. v. khama Irwin, 1957 - NE Botswana and W Zimbabwe; periodic eruptions NE to W Zambia.

E. v. verticalis (A. Smith, 1836) - SW Zimbabwe, SE Botswana and South Africa (except NW); periodic eruptions N to W Zambia.

Descriptive notes. 12-13 cm; 13-21 g. Small, sexually dimorphic lark with appearance like that of a finch (Fringillidae). Adult male nominate race has black head, large white ear patch extending to nape, variable white patch on hindcrown; upperparts dark grey with paler feather margins (general colour varies with wear), wing-coverts and tertials with broad pale margins, appearing scalloped in fresh plumage; tail dark brown, central feathers broadly fringed paler and pattern matching that of upperparts, outer feathers edged and tipped white; chin and entire underparts black, except for narrow white stripe extending from neck down breast side; blackish underwing; eyes brown; bill pale whitish-grey, sometimes with bluish tint; legs pale grey. Female is much duller, browner, rather nondescript, but with blackish belly patch and underwing-coverts, duller, more horn-coloured bill, legs fleshy grey to dull flesh; distinguished from females of congeners by generally paler plumage combined with dark belly patch. Juvenile is browner above than female, with pale feather fringes, face buffish-chestnut, throat and breast buff, mottled darker, belly patch smaller

and browner; male acquires mottled immature plumage in post-juvenile moult 1-2 months after fledging, adult plumage acquired after first complete moult at c. 1 year. Races differ chiefly in upperpart colour and width of pale fringes of wing-coverts and tertials, but variable (general colour changes according to degree of wear): *damarensis* is paler than nominate, male upperparts sandy grey, buffish margins, female more buffish overall, reddish-brown edgings above; *khama* male is pale greyish-white above, whitish margins indistinct, wing-coverts and secondaries with broad white margins, female very pale grey-brown above, whitish below; *harti* is somewhat darker than previous, less greyish above, wing-covert margins less obvious. Voice. Male song, typically in aerial display, a series of simple notes, "shreep shreep shrup-up shreep-eep". Flight call a soft "pink", cleaner and higher-pitched than that of *E. australis*; "prink" when flushed from nest; soft "tsee-ree" feeding call to chicks.

Habitat. Grassy plains in semi-arid regions; also sparse shrublands, fallow fields and cereal croplands in Western Cape (South Africa). In the Kalahari prefers pale calcrete flats and riverbeds to redder sands. Also occurs in variety of more mesic grasslands during irruptions outside its core range. Mostly open lowland plains; scarce in hilly areas.

Food and Feeding. Food mostly seeds; also small amounts of green vegetation (grass shoots, sprouting grass seeds) and insects, including termites (Isoptera), grasshoppers (Acrididae), ants, beetles (Coleoptera). In one study, stomach contents 91% seeds, with grass seeds predominating, lesser amounts of forb seeds. Stomachs of specimens obtained immediately after a rain event contained large numbers of *Hodotermes* harvester termites, this presumably linked to an emergence of winged alates. One pair observed to feed on large number of brown locust hoppers. Chicks fed mostly with insects, especially harvester termites. Forages on ground, mostly by picking seeds from surface, occasionally digging with bill; in loose flocks of up to 100 individuals, sometimes also including other members of genus, as well as *Spizocorys starki*. Seeks shade during heat of day; faces into breeze, with wings drooped, on elevated perch to reduce heat stress, may also fly with dangling legs as cooling mechanism. Regularly drinks water, but some flocks apparently survive without access to water. Metabolic rate typical for species' size, but rate of evaporative water loss significantly lower than expected. Captive individuals maintained constant mass on a diet of dry millet seeds, without water (or with only 0·3 M salt solution) to drink; water-deprived birds produced faecal pellets with 52% water.

Breeding. Associated with rains; laying 2-4 weeks after sufficient rainfall, but interval between rain and onset of breeding varies seasonally (shortest in summer months, longest in winter), related to period needed for grass seeds to mature, also inversely related to amount of rain falling in the first shower; duration of breeding (3-27 weeks) is a function of total amount of rainfall over a few weeks, at least 20-30 mm of rain needed to stimulate some breeding in the Karoo and Kalahari, less than 40 mm to stimulate widespread breeding, rain required also varies seasonally (more needed in summer than in winter, when evaporative losses are reduced); abundance of *Stipagrostis* awns (for lining nests) may be indicator of suitable breeding conditions in N & NW Karoo; breeding more seasonal in SW. Monogamous; solitary, but in favourable areas adjacent nests may be only a few metres apart. Male performs aerial display 10-20 m above ground, circling and calling, sometimes with dangling legs, then drops steeply to ground; also displays on ground with head erect, tail cocked, to mate; during breeding season male fairly often perches on fence wires (female seldom does), suggesting that this behaviour possibly linked to territorial behaviour. Nest built by female, taking 4-5 days, accompanied on some material-gathering trips by male, a shallow scrape in ground with foundation of small stones or hard clods of soil, lined with fine grass leaves, stems and awns, sometimes also wool; where ground hard the foundation is extensive, allowing cup to be sunk into it, in one extreme case nest contained 235 stones with total weight 454 g (largest stone 8 g); site usually on SE or E side of a bush or grass tuft, providing shade from afternoon sun, although winter nests may be in exposed situation. Clutch 2-3 eggs, rarely 1 or up to 5; clutch size changes rapidly with environmental conditions, e.g. mean increased from 2·3 in week before a heavy downpour to 3·2 in week after; laying interval 1 day; incubation usually from first egg, by both sexes roughly equally, male more in afternoons, period 9-13 days (average 9·6 days); eggshells apparently removed by parents, both of which brood and feed chicks, female spends roughly twice as much time in brooding; after feeding, parents wait for chicks to deposit faecal pellet on nest rim, remove this and drop it 3-4 m away; chicks leave nest from day 7, most after 8-10 days, duration of nestling period longer (mean 10·5 days) when heavy rain, typically incited to leave by female, often in response to approach of an intruder; no specific distraction displays, but adults often hover near nest if prevented from returning to it by an observer; young able to fly after 15-20 days. Breeding success generally low owing to high rate of nest predation, primarily by mammals such as mongooses (Herpestidae), sometimes also severe chick mortality caused by heavy rain (77 mm of rain over 2 days killed 59% of chicks); only 47% of clutches survive to due hatch date, 86% of eggs reaching that date hatch, and 60% of broods survive to fledging, giving overall breeding success of 23% and mean of 0·54 young fledged per attempt; predation rates were greater for nests with 2-egg or 3-egg clutches than for those with either 1 or 4 eggs; success in the Kalahari was even lower, only 14% of nests producing fledged young. Maturity probably at 1 year; some males breed in immature plumage.

Movements. Nomadic within core range, with regular dry-season movement to more mesic areas on periphery of range. Mostly a summer breeding visitor in agricultural lands of Western Cape (South Africa). Rainfall seems to be significant trigger for movement within core range, but unclear whether there is regular E-W movement linked to differences in seasonal rainfall between the Kalahari and the Karoo. In areas with relatively little grass, irruptions not solely linked to local rainfall, and may be mediated by absence of suitable conditions in other areas; massive irruption into SW Zambia in 1964 apparently resulted from exceptionally cold conditions farther S. All four races recorded in Zambia, where periodic irruptions of nominate from S, *khama* from SW and *damarensis* from W; last race also reaches W Zimbabwe in some years.

Status and Conservation. Not globally threatened. Common in much of range; locally superabundant after good rains. Breeding densities reach 2-6 pairs/ha in the Namib and 10-15 pairs/ha in the Karoo. Occurs in loose flocks, each seldom containing more than 100 birds, but often many thousands of individuals within one general area; average flock size in the Karoo 35 birds, with average density in open shrubland up to 28 birds/km^2.

56. Chestnut-headed Sparrow-lark

Eremopterix signatus

French: Moinelette d'Oustalet **German**: Harlekinlerche **Spanish**: Terrera Señalada
Other common names: Chestnut-headed Finch-lark

Taxonomy. *Pyrrhulauda signata* Oustalet, 1886, Somalia.
Relationships uncertain; suggested as forming a a superspecies with *E. verticalis*, sometimes expanded to include also *E. nigriceps* and *E. leucopareia*. Race *harrisoni* weakly differentiated, perhaps indistinguishable from nominate. Two subspecies tentatively recognized.
Subspecies and Distribution.
E. s. signatus (Oustalet, 1886) - E & S Ethiopia, N, C & S Somalia and E Kenya.
E. s. harrisoni (Ogilvie-Grant, 1900) - extreme SE Sudan and NW Kenya.

Descriptive notes. 11-12 cm; 16 g. Small, sexually dimorphic lark resembling a finch (Fringillidae). Adult male is strikingly marked, head and breast boldly patterned black and white, hindcrown dark chestnut (appearing blackish in poor light); black areas of face, upper breast and collar sometimes washed chestnut; white nape bordered black below; upperparts sandy brown, wing-coverts with pale fringes, secondaries, tertials and central tail feathers wth buffy margins, base and outer web of outer rectrix white; breast side and flanks white, rest of underparts black; underwing dark brown (appearing blackish in flight); eyes brown; bill greyish-white; legs pale flesh-brown. Female is much duller, mostly dull brown above, rufous-buff supercilium, dirty buff underparts variably mottled on breast, has dark stripe along central belly (often concealed or hard to observe in field); distinguished from female *E. nigriceps* by generally darker upperparts, from female *E. leucopareia* by buffier upperparts, heavier bill, white in outer tail. Juvenile resembles female but paler, with buff margins of upperpart feathers, appearing scaly, face more buffy, breast washed buffy with darker brown streaks; juvenile male moults into an intermediate immature plumage, similar to female *E. leucopareia* but paler above, with heavier bill and usually whitish cheek patches. Race *harrisoni* is colder grey-brown above than nominate. Voice. Male has short twittering song; also reported as giving series of rising, mournful notes as well as piping notes, similar to those of Lesser Striped Swallow (*Hirundo abyssinica*). Flight call a sharp "chip" or "chip-up".

Habitat. Semi-arid and arid plains with grassland, savanna, and clearings in open woodland, from sea-level to 1500 m; in areas with with annual rainfall 75-500 mm.

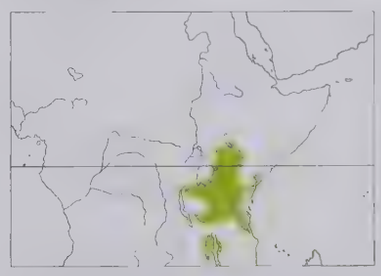
Food and Feeding. Mostly grass seeds; chicks fed with at least some insects. Forages on the ground. In flocks of up to 40 individuals outside breeding season, sometimes in flocks with *E. nigriceps* and *E. leucotis*; seldom with *E. leucopareia*.

Breeding. Apr-Jul. Probably monogamous; nests singly. Male performs aerial display 6-10 m above territory. Nest an open cup built from dry, fibrous grass in shallow scrape in ground, usually at base of a grass tuft; one nest in Somalia was within 20 m of a nest of *E. nigriceps*. Clutch 3-5 eggs; nothing known about parental duties or incubation and fledging periods.

Movements. Resident and locally nomadic. Apparently largely sedentary in core of range, but subject to occasional irruptions at periphery (e.g. in coastal dunes in S Kenya).

Status and Conservation. Not globally threatened. Generally fairly common, but usually outnumbered by *E. nigriceps*. Can be locally abundant when conditions are favourable. Irruptions into Tsavo East National Park, in S Kenya, during 1970s resulted in establishment of a small resident population.

Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Bennun & Njoroge (1999), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lack (1985), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Nikolaus (1987), Shirihai (1996, 1999), Short *et al.* (1990), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).



57. Fischer's Sparrow-lark

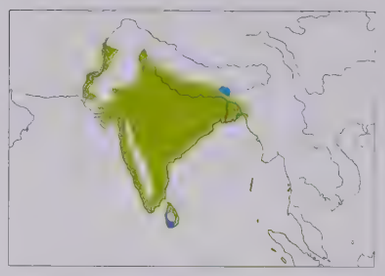
Eremopterix leucopareia

French: Moinelette de Fischer **German**: Braunscheitellerche **Spanish**: Terrera Cariblanca
Other common names: Fischer's Finch-lark

Taxonomy. *Coraphites leucopareia* G. A. Fischer and Reichenow, 1884, Little Arusha, Tanzania.
Relationships uncertain. Sometimes considered to form a superspecies with *E. griseus*, but range is largely parapatric with that of *E. signatus*; has also been considered to form a superspecies with latter, *E. nigriceps* and *E. verticalis*. Plumage varies clinally, on average darker in S, but insufficient to warrant naming of geographical races. Monotypic.

Distribution. NE Uganda and Kenya S to extreme NE Zambia, N Malawi and extreme NW Mozambique.

Descriptive notes. 11-12 cm. Small, sexually dimorphic lark with appearance like that of a finch (Fringillidae); bill slightly more slender compared with those of congeners. Adult male is distinctive, has tawny-rufous (rarely greyish) crown and nape contrasting with white ear-coverts, and black eyestripe, face, throat, neck side and stripe down centre of breast and belly; upperparts grey-brown with paler feather margins, these especially obvious on wing-coverts; flight-feathers darker brown, tertials and outer tail edged rufous; underparts (except central black band) whitish, with variable rufous wash on side of breast; eyes brown; bill pale grey, slightly darker tip; legs pale grey-brown to pinkish-flesh. Female is much duller, crown and cheeks brownish with darker streaks, supercilium and side of neck buffy rufous, distinctive narrow black stripe down centre of breast and belly; distinguished from females of congeners mainly by black stripe below, from immature male *E. signatus* by darker cheeks and less heavy bill. Juvenile is like female, but with pale buff nape patch, pale feather tips on upperparts and wing-coverts, smaller belly stripe often barely visible; juvenile male moults into an intermediate, mottled immature plumage.



Voice. Typical call a rather sharp "tsee tsit"; song has added notes, resulting in rather tuneless warble not unlike that of a sparrow (*Passer*).
Habitat. Semi-arid grassland and bare areas, including bare fields, roads and airstrips.
Food and Feeding. Mostly grass seeds, with a few insects; survives well in captivity on a diet of seeds. Birds breeding at Magadi, in S Kenya, take large numbers of adult and larval flies (Diptera) associated with soda streams. Forages on the ground, in small flocks; picks food items from the soil or directly from plants. Nesting birds often join feeding flocks in late afternoon.
Breeding. Season protracted, nesting mostly during Feb-Jul rainy season in N and during Apr-Aug dry season in C & S. Monogamous; breeds singly or in loose "colonies". Male performs high aerial display, also sings from ground; approaches female while holding chestnut crest erect. Nest an open cup, lined with dry grass and rootlets, built in shallow scrape in ground, usually at base of a grass tuft or other feature (including shrub, rock or even a post) but fully exposed to midday sun; where ground hard, builds a foundation of pebbles or clods of earth in which to make a depression. Clutch 2-3 eggs, rarely 4; incubation by both parents, contributing roughly equal shares, and changing over regularly during heat of day, then standing over eggs to shade them, also regularly turning eggs, apparently to prevent them from overheating; nest often left unattended in early morning and evening; incubation period c. 12 days; incubating and brooding birds raise the feathers to shed heat; fledging period c. 15 days, although chicks probably leave nest before this time.
Movements. Resident or local nomad; perhaps regular migration in S of range, where it visits Malawi and adjacent Zambia in winter dry season.
Status and Conservation. Not globally threatened. Fairly common to common. Up to 20 breeding pairs in 0·5 ha in areas where conditions favourable; usually occurs in flocks, even when breeding. Range may have contracted in NE; in Kenya, occurred in Tsavo East National Park until 1960s, but now replaced there by *E. signatus*. In contrast, possibly expanding its range in S, becoming more common in Malawi; first recorded in NE Zambia in 1970s, despite frequent searches prior to this time.
Bibliography. Aspinwall (1977a), Benson & Benson (1977), Byaruhanga *et al.* (2001), Dowsett (1983), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Karcher & Medland (1989), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1962), Medland (1995), Reynolds (1977), Short *et al.* (1990), van Someren (1956), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

58. Ashy-crowned Sparrow-lark

Eremopterix griseus

French: Moinelette croisée **German**: Grauscheitellerche **Spanish**: Terrera Coronigrís
Other common names: Ashy-crowned Finch-lark, Black-bellied Sparrow-lark/Finch-lark, Ceylon Finch-lark

Taxonomy. *Alauda grisea* Scopoli, 1786, no locality = Gingee, South Arcot district, Tamil Nadu, India. Relationships uncertain. Sometimes considered to form a superspecies with *E. leucopareia*, but often regarded as close to *E. nigriceps*. Monotypic.
Distribution. Pakistan (R Indus plains), and from S Himalayan foothills E to E Bangladesh and S to S tip of India, also Sri Lanka.
Descriptive notes. 11-12 cm. Small, sexually dimorphic lark with appearance superficially like that of a finch (Fringillidae). Adult male has pale greyish-brown forehead and crown (forehead often slightly paler, crown indistinctly streaked), black lores and eyeband, pale greyish-brown or pale buffish ear-coverts, grey-brown nape; upperparts grey-brown, lightly streaked, upperwing-coverts, tertials and flight-feathers darker with pale edges, pale tips of especially median coverts; underwing-coverts blackish; tail blackish-brown or dark grey-brown, central feather pair paler, outermost pair dusky grey-brown, outer two pairs with off-white outer web; throat, neck side and underparts blackish, narrow whitish band on breast side and flank; bill grey; legs pinkish. Differs from *E. nigriceps* in less black on head, duskier ear-coverts. Adult female lacks black on the head and underparts (but has blackish-brown underwing-coverts), is grey-brown and faintly streaked above, with indistinct buffish supercilium, pale crescent behind grey-brown ear-coverts, buffish below, breast indistinctly streaked dark; distinguished from very similar female *E. nigriceps* (of race *melanauchen*) by marginally darker, browner and more distinctly streaked upperparts, darker and more buffish underparts, on average diffuser and broader streaks below (often also on flanks), generally slightly more contrasting head pattern. Juvenile resembles female, but with whitish fringes of scapulars and upperwing-coverts; some first-adult males show reduced black on head and underparts. Voice. Song, mainly in high flight, also from ground or low perch, strophes of quickly repeated short notes, e.g. "plü-plü-plü-plü-plü-plü-plü-plü-plü-plü-plü-plüü" or "drrü-drrü-drrü-drrü-drree-drree-drree", strophes interspersed with somewhat melancholy, drawn-out, whistled "eeeeeeeee" (given also during descent from flight, also from ground); alternatively, short strophes of slightly more varied, often quickly repeated, whistles, e.g. "eee-peee, pee-pee-pee". Commonest call rather faint, soft, rolling "djürr(i)t".

Habitat. Dry open habitats with scattered low vegetation, from sea-level to c. 1000 m. Generally completely segregated by habitat from *E. nigriceps* (of race *melanauchen*) where their ranges overlap.
Food and Feeding. Poorly studied; diet seeds, e.g. of grasses and forbs (Chenopodiaceae), and insects, e.g. small beetles (Coleoptera). Forages on ground.
Breeding. Little studied. Breeds more or less throughout year, but mainly Feb-Sept in peninsular India and May-Jun in Sri Lanka; probably at least sometimes two broods. Male song flight high up, intermittently dropping down and rising in deep undulation, final descent very deeply undulating. Nest, built mainly or entirely by female, a depression on ground, lined with fine grass, rootlets, hair or feathers, and frequently surrounded by gravel, generally sheltered by stone, clod of earth or small bush. Clutch 2-3 eggs; incubation by female, or possibly by both parents; chicks fed by both sexes, leave nest before capable of flying.
Movements. Sedentary or slightly nomadic.
Status and Conservation. Not globally threatened. Locally common. No population estimates. Present in numerous protected areas, e.g. Ranthambhore Sanctuary (India) and Kosi Tappu Wildlife Reserve (Nepal).

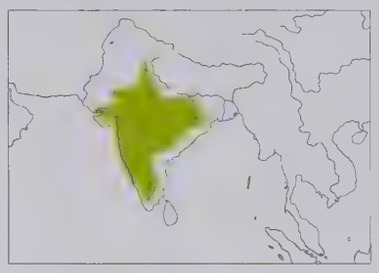
59. Bar-tailed Lark

Ammomanes cinctura

French: Ammomane élégante **German**: Sandlerche **Spanish**: Terrera Colinegra
Other common names: Bar-tailed Desert Lark/Sand Lark, Black-tailed Lark/Desert Lark/Finch-lark

Taxonomy. *Melanocorypha cinctura* Gould, 1839, São Tiago, Cape Verde Islands.
Has been thought to form a superspecies with *A. phoenicura*, and in the past considered conspecific. Paler and smaller birds from Chad (Ennedi) and Sudan sometimes separated as race *pallens*, but appear indistinguishable from *arenicolor*. Three subspecies recognized.
Subspecies and Distribution.
A. c. cinctura (Gould, 1839) - Cape Verde Is (São Tiago, Maio, Boavista, Sal).
A. c. arenicolor (Sundevall, 1850) - Sahara Desert from S & E Morocco E to Libya (Cyrenaica) and Egypt (including Sinai Peninsula) and S, discontinuously, to W & SE Mauritania, WC Mali, C Niger, N & E Chad and C & NE Sudan; also Middle East (S Israel, Jordan, Iraq) and Arabian Peninsula.
A. c. zarudnyi Hartert, 1902 - E Iran E to S Afghanistan and S Pakistan.



Descriptive notes. 14 cm; 14-23 g. Small, neat, rather plain lark with relatively small and rounded head, short bill, long primary projection (about half length of tertials), relatively long outer primary (1 mm less to 5 mm more than primary coverts), rather short and slender tarsus; hind claw short (5·3-6·8 mm), slightly curved. Nominate race is mostly tawny rufous above, faint buffish supercilium; flight-feathers and tail orange-rufous, broad blackish tips of primaries (contrast with tertials when wings folded), well-demarcated black terminal tailband; pale whitish-buff below, breast washed orange; bill sandy pink; legs sandy horn to pale brown. Sexes alike. Juvenile is similar to adult, but black on tail and primaries less defined (sometimes lacking on primaries), outer primary broader-tipped and longer (extends 6-9 mm beyond tips of primary coverts). Race *arenicolor* is paler than nominate, more sandy pinkish, black on tail and primaries less extensive; *zarudnyi* is much greyer above, less white below, with broader black tailband. Voice. Male song, often in aerial display, short whistles, "see-oo-lee" or "cher-ho-hee", first notes lower in pitch and often audible only at short distance, the last one high, pure and squeaky; repeated rhythmically at intervals of c. 1·5 seconds. Calls include dry, purring "prrit" or "cherr" and thin, descending "peeyu" or "see-oo".
Habitat. Most desert-adapted lark of Palearctic. Inhabits mainly deserts with less than 100 mm annual rainfall, also semi-deserts, in flat or gently undulating terrain, stone or sandy soils, and very sparse or almost no vegetation cover. In W part of Sahara prefers stone-clay *regs* (gravel plains with mixed sandy areas) with grasses, and small depressions in the terrain; common in semi-arid savanna. Generally lowlands; may reach 1700 m in Pakistan after breeding season.
Food and Feeding. Seeds, to lesser extent other plant material, and insects. In Cape Verde Is mostly small seeds and grasshoppers (Acrididae); in Western Sahara during breeding season small seeds (mainly of *Aizoon*) and insects; in Algeria seeds. Diet of chicks insects. Forages on ground; in small flocks when not breeding. Searches ground, walks and runs sequentially; also digs for items.
Breeding. Season determined by rainfall; lays Jan-Apr in N Africa, Sept-Jun in Cape Verde Is, depending on dry period; mostly mid-Mar to mid-Apr in Middle East; some pairs double-brooded. Male song flight steeply undulating, notes uttered in phase with undulations, flightpath meandering but roughly circular, ending with steep descent to ground. Nest built by female, unknown if male helps, a shallow depression on ground beneath a rock or beside a stone, lined with some vegetation, rampart of small pebbles, interior diameter 7-8 cm, oriented to N. Clutch 2-4 eggs, rarely 5 (mode 2 in Cape Verde Is, 3 in Algeria and Tunisia); incubation by both sexes, 12-14 days; chicks cared for and fed by both parents, leave nest at c. 11 days, fledging 13-15 days.
Movements. Resident; dispersive winter movements in search of less arid areas recorded in N Africa, especially during drought periods; nomadic over short distances in Middle East and Arabian Peninsula. Occasional longer dispersal indicated by records of vagrants in Canary Is, Balearic Is (Mallorca), Italy (both peninsula and Sicily), Malta and Cyprus.
Status and Conservation. Not globally threatened. Abundance varies widely within rather large but fragmented range. In Cape Verde Is abundant on Sal, Boavista and Maio, rare on Fogo; in Mauritania local in N and widespread and fairly common in S; common in S Morocco and S Tunisia; abundant in sublittoral zone of Western Sahara, becoming progressively scarce inland; in Libya widespread in Tripolitania and common in Cyrenaica; locally common in Egypt; frequent in WC Mali and in N Niger (Ténéré); fairly common in N Sudan. Fairly common in parts of Israel, mainly W Negev and Arava Valley, estimated total for whole country in 1980s 400-500 pairs, but declining; widely distributed but uncommon in Jordan (commonest lark in hammada areas of Azraq); widespread and often common in Saudi Arabia, where common to very common in C deserts and Gulf area); locally common and widespread in S Baluchistan. Elsewhere, only few records from Syria, scarce and irregular in Kuwait (first confirmed breeding 1996), and recorded in Abu Dhabi (1992); reported from S Turkey (but records possibly relate to *A. deserti*) and once from N Yemen.

60. Rufous-tailed Lark

Ammomanes phoenicura

French: Ammomane à queue rouge **German**: Rotschwanzlerche **Spanish**: Terrera Colirroja
Other common names: Rufous-tailed Desert Lark/Finch-Lark

Taxonomy. *Mirafra phoenicura* Franklin, 1831, Vindhya Hills between Benares and Gurrah Mundela on the Narbudda, India.
Has been thought to form a superspecies with *A. cinctura*, and in the past considered conspecific. Is, however, more similar morphologically, vocally and in habitat choice to *A. deserti*, and likely to be more closely related to that species. Birds from S India often separated as race *testacea*, but appear indistinguishable from other populations. Monotypic.
Distribution. NE Pakistan (probably irregular) and most of India (except NW, N & NE).

Descriptive notes. c. 16 cm. Rather robust and quite strong-billed, fairly dark and featureless lark. Adult is plain dark brown-grey above, faint paler supercilium; wings dark grey-brown with indistinct paler edges; uppertail-coverts and tail rufous, tail with broad dark terminal bar; throat and upper breast rufous-buff, rest of underparts rufous, dark streaking on breast, underwing mostly deep rufous; iris dark brown; bill mainly dark grey above, pale greyish-pink below with dark tip; legs pinkish to dull fleshy brown, often duskier on toes. Sexes similar, female on average smaller than male. Juvenile differs from fresh-plumaged adult in having slightly more distinct pale buffish-rufous fringes above. Voice. Song, from ground or low perch such as rock, or in low flight, 2-3 simple notes, given one at a time in seemingly random order with short pauses in between, e.g. "juu, juuh, tchérrrwe, tchérrrwe, tchérrre ... juuh ... tchérrrwe ...": sometimes short warbling strophes intermixed. Commonest call a subdued, soft "djup". Vocalizations resemble those of *A. deserti*.
Habitat. Dry, open habitats with sparse vegetation; often found together with other species, such as *Eremopterix griseus*.
Food and Feeding. Food poorly studied: seeds, for instance of grasses and cereals, and invertebrates, e.g. beetles (Coleoptera). Forages on ground.
Breeding. Feb-May, chiefly Mar and Apr. Male song flight of brief duration, at low level, undulating on horizontal flightpath, similar to that of *A. deserti*. Nest, built by both sexes, a depression on ground, generally sheltered by clod of earth, tuft of grass or other plant, lined with fine grass and often surrounded by pebbles, small sticks, etc. Clutch 2-4 eggs; uncertain whether incubation by female alone, but both sexes feed young; incubation and fledging periods not documented.
Movements. Mostly sedentary; apparently somewhat nomadic in non-breeding season.
Status and Conservation. Not globally threatened. Locally common; common in N part of Indian range. No population estimates. Status in Pakistan uncertain; possibly only erratic visitor during monsoon season. Recorded in W terai of S Nepal, where apparently very rare and local; breeding status requires confirmation.
Bibliography. 61. Desert Lark

Ammomanes deserti

French: Ammomane isabelline **German**: Steinlerche **Spanish**: Terrera Sahariana
Other common names: Desert Finch-lark, Sand Lark(!)

Taxonomy. *Alauda deserti* M. H. K. Lichtenstein, 1823, Aswan, upper Egypt.
Was in the past thought to form a superspecies with *Ammomanopsis grayi*, but apparent similarities now attributed to convergence. Similar morphologically, vocally and in habitat choice to *A. phoenicura*, and likely to be more closely related to that species. Geographical variation complex, and numerous races named mainly on basis of plumage coloration, which in turn seems strongly related to predominant soil colours; pale and dark birds live side by side in some areas, e.g. Algeria (Hoggar Mts), Nile Valley and Jordan. Although over 30 races have been described, many now usually merged with others, often in rather arbitrary way, for example: *bensoni* (grey-coloured) and *janeti* (brown) from Hoggar Mts have been included variously in *geyri* or *whitakeri*; *intermedia* (from El Golea area of Algeria) in *mya* or *algeriensis*; *mirei* (from Tibesti Mts, in Chad) in nominate race, *whitakeri* or *algeriensis*; *monodi* (from the Iriji, in Mauritania) in *payni* or *geyri*; *katharinae* (from Sinai Peninsula) in nominate or *isabellina*; *hijazensis* (from Arabian W coast) in *samharensis* or *isabellina*. In addition, *fratercula* (described from Dead Sea region) and *borosi* (from lower Nile Valley in EC Egypt) considered inseparable from *isabellina*. Races *iranica* and *phoenicuroides* said to intergrade widely in Afghanistan and Pakistan (in region from Kandahar E to Quetta). Thorough review of taxonomy required. Twenty-four subspecies tentatively recognized.
Subspecies and Distribution.
A. d. payni Hartert, 1924 - Morocco (S of High Atlas Mts) and nearby SW Algeria.
A. d. algeriensis Sharpe, 1890 - N Algeria (N of 31° N), Tunisia and NW Libya (W Tripolitania).
A. d. mya Hartert, 1912 - C Algeria (Sahara between 30° N and 27° N).
A. d. geyri Hartert, 1924 - Mauritania E to S Algeria and NW Niger (Aïr Massif).
A. d. whitakeri Hartert, 1911 - SE Algeria (including Hoggar Mts) and SW Libya, perhaps also NW Chad (Tibesti Mts).

Tibetan Lark (*Melanocorypha maxima*); 66. Mongolian Lark (*Melanocorypha mongolica*); 67. White-winged Lark (*Melanocorypha leucoptera*); 68. Black Lark (*Melanocorypha yeltoniensis*).

A. d. kollmanspergeri Niethammer, 1955 - NE Chad (Ennedi Mts) and W Sudan (Darfur).
A. d. isabellina (Temminck, 1823) - N Egypt (from W of Nile Valley and Dakhla Oasis) E to S & E Israel, S Jordan, NW Saudi Arabia and S Iraq (E to R Tigris).
A. d. deserti (M. H. K. Lichtenstein, 1823) - E Egypt (E of R Nile to Red Sea) S to Sudan.
A. d. erythrochroa Reichenow, 1904 - W Chad (Ndjamena) E to N Sudan (Dongola S to Kordofan).
A. d. samharensis Shelley, 1902 - Red Sea coasts of Sudan, Eritrea (S to Mits`iwa) and Arabian Peninsula (S to Yemen border).
A. d. assabensis Salvadori, 1902 - Ethiopia and NW Somalia.
A. d. akeleyi Elliot, 1897 - highlands of N Somalia.
A. d. coxi Meinertzhagen, 1923 - S Turkey (Birecik), Syria and N Iraq (E to Samarra and Al Fallujah).
A. d. annae Meinertzhagen, 1923 - black lava deserts of Jordan (Azraq area), probably also extreme S Syria.
A. d. azizi Ticehurst & Cheesman, 1924 - NE Saudi Arabia (Al Hufuf area).
A. d. saturata Ogilvie-Grant, 1900 - black lava deserts of S Arabia (N Hijaz S to Aden).
A. d. insularis Ripley, 1951 - Bahrain, in Persian Gulf.
A. d. taimuri Meyer de Schauensee & Ripley, 1953 - Oman (Muscat area).
A. d. cheesmani Meinertzhagen, 1923 - E Iraq (E of R Tigres) to W Iran (S, W of Zagros Mts, to Persian Gulf near Bandar e Bushehr).
A. d. darica Koelz, 1951 - SW Iran (S Zagros Mts).
A. d. parvirostris Hartert, 1890 - W Turkmenistan (Kara-Bogaz-Gol S to Kopet Dagh and Atrak Basin).
A. d. orientalis Zarudny & Loudon, 1904 - NE Iran (N Khorasan), Turkestan (S Turkmenistan, S Uzbekistan, S Tadjikistan) and N Afghanistan.
A. d. iranica Zarudny, 1911 - E Iran (E of Tehran) E to SW Afghanistan and W Pakistan (Baluchistan).
A. d. phoenicuroides (Blyth, 1853) - SE Afghanistan, E Pakistan and adjacent NW India (extreme W Rajasthan).

Descriptive notes. 15-17 cm; c. 20-30 g. Medium-sized, robust lark with relatively large head, rather heavy bill (size changes geographically), longish wings with long primary projection, rather short tail; hind claw short (5-8 mm), slightly curved. Nominate race has short, indistinct buff supercilium, faint pale eyering, faint dark loral stripe; plain dark grey-brown to isabelline-brown above, rump tinged rufous; primaries with rufous outer webs, relatively long and broad outer primary (extends 4-15 mm beyond tips of primary coverts), tertials brownish; rufous-tinged tail feathers becoming blackish-centred towards tips, forming diffuse, triangular-shaped terminal band; throat whitish, underparts buffish, chest with diffuse streaking; iris dark brown; bill pale brown to yellowish, with darker grey-horn culmen and tip; legs dull flesh to greyish or yellowish-brown, often duller on toes. Sexes similar. Juvenile has narrow pale tips on wings and underparts, no blackish band on tail, outer primary longer than adult (11-18 mm beyond tips of primary coverts). Races vary markedly, especially in coloration, which often matches closely that of local soils (tending to be isabelline on sands, reddish to grey on rocks, and blackish in races living in black lava deserts), also in size, with comparatively long wing and long bill in C Sahara, long wing but shorter bill in E of range, and around them races of intermediate measurements, the others being comparatively small: *payni* is dark pinkish-grey to greyish-cinnamon above, darkish pink-buff below; *algeriensis* is much paler above and below than previous; *mya* is slightly paler and more sandy than last, lower back and rump less reddish, also larger in size, bill longer and stouter; *geyri* has generally darker, less sandy (more greyish-brown) plumage than last; *whitakeri* is darker than previous races, darker grey-brown above (only slight vinous tinge in fresh plumage), rump contrastingly rufous-cinnamon, buffish-brown with strong grey-brown streaks below, resembles nominate but much larger; *kollmanspergeri* is dark reddish-brown above, rufous below; *isabellina* is small and pale, generally light sandy to pale buff-brown with greyish or pale olive-grey tinge above, buff or creamy buff below, tail rufous with triangular black area at tip; *coxi* resembles previous but larger; *erythrochroa* is much paler than nominate, like previous but somewhat more reddish-yellow; *samharensis* is much darker, dark grey-brown above, sandy buff below, like nominate but darker throughout; *assabensis* closely resembles last, but marginally darker; *saturata* is very like previous two, but bill longer and stouter; *annae* is darkest race, very dark sooty grey to almost blackish; *akeleyi* is small, rather pale sandy grey above, rump dark pinkish-buff, pinkish-buff below; *azizi* is palest race, plumage creamy to pale isabelline; *insularis* is pale vinaceous grey above; *taimuri* resembles nominate; *cheesmani* is dark sandy brown with strong pink tinge above, pinkish-brown below; *iranica* is rather large, dark grey above, rump dull rufous, greyish-tinged buff-brown below, extensive grey spots and streaks from chin to breast, bill rather short but heavy; *darica* is slightly paler than last; *parvirostris* resembles previous but bill smaller; *phoenicuroides* is slightly browner than last, bill thinner; *orientalis* is large, rather pale, greyish sandy. VOICE. Male song, usually in flight, also from ground, far-carrying, melodious trilled whistles, "trreooee". Calls variable, including "chu" while foraging and "chee-lu" or "chee-wu" in flight, rapidly repeated when excited.

Habitat. Throughout range occurs in desert or semi-desert, mainly in lowlands. Found on rocky or stony hill slopes and flanking escarpments; avoids flat and sandy landscapes, although sometimes seen in undulating terrain with rocks and stones. Occurs along roadsides in some areas. Mostly lowlands, but to at least 2000 m in mountains, e.g. to above 2250 m in Egypt (Sinai); to 3000 m in Chad (Tibesti).

Food and Feeding. Mixed diet; small seeds and insects taken in highly variable proportions, according to areas and seasons. In Western Sahara during spring mainly seeds, but also small locusts (Orthoptera) and beetles (Coleoptera); in Algeria in spring, seeds; in Turkmenistan in spring and summer, approximately same frequency of seeds and invertebrates, the latter mainly caterpillars, grasshoppers (Acrididae) and beetles. Chicks fed mainly with insects, although some seeds recorded. Forages singly or in small groups, by walking on ground or among stones; frequently picks in dung; also recorded as feeding in shrubs, also as capturing flying insects. Hard food items broken against rock or other solid surface before swallowing. Drinks water, and large numbers may gather at water sources in summer; also able to survive without water.

Breeding. Lays Mar-May in N of range, Feb-Apr in S; Apr-Jun in Somalia; 1-2 broods per year. Monogamous; territorial. Male song flight rather brief, either horizontal between two eminences, with deep undulations, or steep ascent from and return to ground, with or without horizontal phase. Nest built by both sexes, on ground beside rock, grass tuft or small shrub, or in exposed site, made from grass stems and other fine plant material, lined with softer material, with rampart of small stones on exposed side, or surrounded by small stones when in open site. Clutch 1-5 eggs, smaller (2-3 eggs) in desert areas (mode 4 in Algeria and Tunisia, 3-4 in Israel); incubation by female alone, period 10-11 days, in Israel 13-14 days; chicks cared for and fed by both parents, nestling period c. 9-11 days, fledging 14-15 days. High rate of nest predation, c. 65 % in some areas.

Movements. Resident. Mainly sedentary, although some irregular movements recorded; altitudinal movements in mountain areas, with post-breeding descent to lower elevations. Accidental in Lebanon and Cyprus.

Status and Conservation. Not globally threatened. Widespread and common to locally common in many parts of extensive range. Common in much of African range, but apparently rather uncommon in Mauritania; some expansion to N recorded in E Morocco, and recently recorded also in Burkina Faso. Common in Arabia and most of Middle East; numerous in Israel (at least 10,000 pairs in 1980s) and Jordan, breeds in many places in interior Syria (with marked annual fluctuations), widespread in Iraq; small numbers in W Kuwait, breeding only in years of good winter rainfall; first found in Turkey in 1983, restricted to Birecik area. Common in Pakistan; uncommon in India.

Genus *RAMPHOCORIS* Bonaparte, 1850

62. Thick-billed Lark
Ramphocoris clotbey

French: Alouette de Clot-bey **German**: Knackerlerche **Spanish**: Calandria Picogorda
Other common names: Clotbey(`s) Lark

Taxonomy. *Melanocorypha clot-bey* Bonaparte, 1850, Egyptian Desert.
Spelling of genus name often emended to *Rhamphocorys*. Monotypic.

Distribution. Deserts of NW Africa (Western Sahara, extreme N Mauritania, S & SE Morocco, W & interior N Algeria, C & S Tunisia, NW Libya), C Jordan and N Saudi Arabia.

Descriptive notes. 17-18 cm; male c. 52-55 g, female c. 45 g. Rather large lark with heavy head, huge deep-based bill laterally compressed distally (with small tooth in lower mandible that fits in notch in upper one), rather long and broad-based wings with narrow and pointed outer primary reduced (falls 4-12 mm short of primary-covert tips), shortish tail slightly forked; legs long, claws rather short (hind claw 6·7-8·5 mm) and slightly curved. Adult male has black face with distinct white patch on lower side, white chin; crown and upperparts pink-isabelline with grey tones, greater and median coverts with blackish centres and broad pinkish-brown edges, tertials blackish-brown with broad buff fringes; remiges mostly black, broad white tips of secondaries and inner primaries (striking wing pattern in flight, with broad white trailing edge); blackish subterminal tailband (more noticeable from below); pale buffish underparts strongly blotched black, black underwing with broad white trailing edge; iris dark brown; bill pale bluish-grey with darker tip; legs dull bluish-grey to pale straw. Female differs from male in having black areas of head less intense, more greyish, underparts less heavily blotched, bill pale horn with darker tip. Juvenile has only faint markings on head and underparts, bill less heavy, outer primary rounded at tip and longer (from 1 mm short of to 2 mm beyond tips of primary coverts). VOICE. Male song, from ground or in flight, a jingling series described both as soft and rather quiet medley of tinkling and warbling notes and as rapid stanza of twittering notes. Calls include sharp "prit", given commonly in flight, also "coo-ee", "co-ep", "wick-wick", "wheet-wheet-wheet", "sree", and similar; alarm a long, plaintive whistle, "tsu-ee".

Habitat. Borders of deserts, including true desert, with annual rainfall less than 200 mm; prefers flat or undulating terrain, but sometimes occurs on slight slopes. Mostly on stony or compact soils, as in hammada areas; also wadi beds. Habitats occupied in N Africa range from open *Stipa* or *Lygeum* steppes to arid areas with widely variable vegetation types, including wormwood (*Artemisia*) shrubs or succulent *Aizoon*, and to very barren areas.

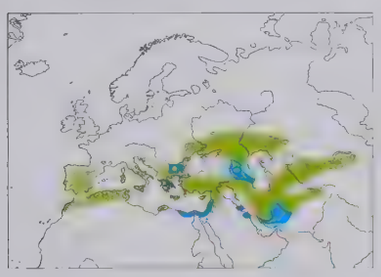
Food and Feeding. Seeds, invertebrates and green plant material. In Western Sahara takes ants, other insects, and some seeds; in W Algeria and NC Sahara mostly green material, insects and seeds, also a small lizard; in Jordan diet includes small fruits of *Euphorbia kahirensis*. Locusts (Orthoptera) reported as fed to chicks. Forages singly or in small flocks. Searches on ground, sometimes hopping; pulls branches down to ground to reach seeds; also digs. Not clear if it needs water, but flocks recorded at watering points.

Breeding. Lays Feb-May. Song-flighting male apparently rises to considerable height, and descends by parachuting in zigzag. Nest a shallow scrape lined with vegetation, on ground beneath or beside bush or stone, with rampart of pebbles on exposed side; occasionally built in open site. Clutch 3-5 eggs (mode 4); female recorded as incubating, chicks fed by both parents; no information on incubation and nestling periods, nor on fledging period of chick.

Movements. Resident; mostly nomadic in non-breeding season, normally in small parties, although flocks of up to 50 individuals recorded in Morocco. Rare and irregular visitor to Egypt; uncommon winter visitor to C & S Saudi Arabia, and small numbers seen occasionally in W Kuwait and nearby regions. Sporadic visitor to S Israel; vagrant in S Yemen.

Status and Conservation. Not globally threatened. Relatively small breeding range highly discontinuous and imperfectly known. Widespread and frequent to sparse in NW Africa, where rather scarce in sublittoral zone of Western Sahara, and rare, perhaps scarce, breeder in Tunisia; uncommon to abundant in S & SE Morocco, found in flocks of up to several dozen, with a winter record of "thousands" at Jerada Pass. Two old records from NE Libya (El Mechili, in Cyrenaica). In Saudi Arabia probably uncommon resident in N deserts, with small numbers breeding in Harrat Al Harrah Reserve; scarce in Jordan, breeding not confirmed until 1990. Has bred Egypt (1995) and Israel (1999), and old breeding record from "Syrian desert" (1930s).

Bibliography. Bergier & Bergier (1990), Borrow & Demey (2001), Brosset (1956, 1961), Bundy (1976), Bundy & Morgan (1969), Bundy & Warr (1980), Clancey (1993a), Clarke (1980), Cramp (1988), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dupuy (1969), Étchécopar (1975), Étchécopar & Hüe (1964), Fishpool & Evans (2001), Goodman & Watson (1983), Goodman *et al.* (1989), Granit (1999), van Heezik & Seddon (1999), Heim de Balsac (1936), Heim de Balsac & Mayaud (1962), Hollom *et al.* (1988), Hüe & Étchécopar (1970), Isenmann & Moali (2000), Jennings (1981, 1995), Keith *et al.* (1992), Ledant *et al.* (1981), Mayaud (1985), Meinertzhagen (1951, 1954a), Shirihai (1996), Smith (1965), Snow & Perrins (1998), Svensson *et al.* (1999), Thévenot *et al.* (2003), Thomsen & Jacobsen (1979), Valverde (1957), Wallace (1983).



Genus *MELANOCORYPHA* Boie, 1828

63. Calandra Lark

Melanocorypha calandra

French: Alouette calandre **German**: Kalanderlerche **Spanish**: Calandria Común
Other common names: European Calandra Lark

Taxonomy. *Alauda calandra* Linnaeus, 1766, Pyrenees, Spain-France border.
Geographical variation rather slight, and small clinal increase in size from W to E. Described race *dathei* (from SE Turkey) considered synonymous with *gaza*. Four subspecies recognized.
Subspecies and Distribution.
M. c. calandra (Linnaeus, 1766) - Iberia and S France E to S Russia and NW Kazakhstan, S (including Mediterranean islands of Sardinia, Sicily, Crete, Cyprus) to NW Africa (N Morocco E to NW Libya), Turkey (except SC & SE), Transcaucasia and NW Iran.
M. c. hebraica Meinertzhagen, 1920 - SC Turkey and adjacent NW Syria S to Israel, Palestine and W Jordan.
M. c. gaza Meinertzhagen, 1919 - SE Turkey, E Syria, Iraq and SW Iran.
M. c. psammochroa Hartert, 1904 - N Iraq and N Iran (Zagros Mts E to Khorasan) E to Turkmenistan and E Kazakhstan.

Descriptive notes. 18-20 cm; male c. 54-73 g, female 44-66 g. Large, quite robust lark with deep-based heavy bill markedly downcurved on culmen, rather long broad-based wings with strongly reduced outer primary (falls 12-18 mm short of primary-covert tips), primary projection at least half length of tertials, shortish tail; hind claw long (11-16 mm) and straight. Nominate race has fairly obvious pale supercilium and area around eye; greyish-brown and well streaked above, large dark feather centres; secondaries and inner primaries white distally (broad white trailing edge in flight); outer rectrices white; underparts off-white, chest spotted and streaked black, characteristic large black patch on side of upper breast, tawny brown tinge to rear flanks; underwing blackish (striking in flight); iris dark brown; bill pale, dark culmen and tip; legs pinkish to orange-flesh. Sexes similar, female sometimes with breast-side patch less marked. Juvenile is paler, with white feather tips on upperparts and less apparent breast patches, outer primary longer (1 mm short of to 2 mm beyond tips of primary coverts). Race *psammochroa* is paler than nominate, tinged cinnamon in fresh plumage, dark centres on upperparts rather narrow, breast spots very small; *hebraica* is more or less intermediate, although chest spots rather large; *gaza* differs from previous in being paler grey above, with dark centres narrower. Voice. Song, usually in flight but sometimes from ground, an extended medley of rolling trills mixed with harsh chirping sounds (e.g. "schreee", "khitra"), with frequent mimicry of other bird species; similar to that of *Alauda arvensis*, but broken by short pauses and with more harsh chirps, overall less musical, but more varied and powerful. Flight calls typically dry, sharp trills.
Habitat. Open plains, from steppes and pastures to extensive dry cereal cultivations; true steppe, with dense grass cover, probably the original habitat, but in Mediterranean Basin mainly dry pastures and dry cultivations used. In cultivated areas prefers fallows, long-fallows and field edges; to lesser extent sown fields, selecting unirrigated legumes and barley fields. Avoids deserts and semi-deserts, as well as rocky areas. Mainly lowlands, but reported at up to 1400 m in Spain; locally to at least 2000 m in Turkey and C Asia.
Food and Feeding. Mainly insects during spring, and seeds and shoots in winter. Wide variety of invertebrates, dominated by grasshoppers (Acrididae) and caterpillars; seeds mostly of cereals and weeds. Energy consumption of free-living individuals estimated at 320 kJ per day. Needs to drink water. Forages on ground, singly or in small flocks; often in large flocks, sometimes mixed with Corn Buntings (*Miliaria calandra*), outside breeding season. Runs on ground, picks items from surface; digs with the bill. Occasionally hovers to inspect tops of small bushes.
Breeding. Laying from early Apr to Jul (groups of males arrive in breeding areas in Feb-Mar); two broods per season. Monogamous. Solitary and territorial, but semi-colonial where density high. Male song flight may reach great heights and last many minutes (up to c. 30 minutes recorded). Nest built by female, sometimes assisted by male, in shallow depression on ground, often under tussock, made from grass stems and small leaves, lined with softer material, internal diameter 8 cm. Clutch 3-6 eggs (mode 4-5), largest clutch size in middle of laying season; replacement laid if first clutch lost; incubation by female alone, from last or penultimate egg, period 11-13 days, occasionally longer; chicks brooded by female during first 1-3 days, then cared for and fed by both parents, nestling period 8-10 days, fledging period 19-22 days. Nestling mortality rate relatively low, 34%.
Movements. Mediterranean populations chiefly resident, but outside breeding season wandering in flocks. E populations migratory or partially migratory, wintering from S Russia S to N Africa (scarce visitor in Egypt), S Iraq and S Iran; passage in Russia mainly Oct and Mar. Vagrants recorded N to Britain, Netherlands, Germany, Poland, Norway, Sweden, Finland, also W to Madeira and S to E Arabia.
Status and Conservation. Not globally threatened. Common to very common in many parts of range; rare, and declining, in others. In Europe, populations concentrated mainly in Iberia and Russia; estimated 10,000-100,000 pairs in Portugal; very common and widespread in Spain (except in N humid belt, littoral regions and mountain areas), 1,030,000-3,400,000 pairs, with densities of up to 2-3 birds/ha in favoured areas; 5000-15,000 pairs in Italy, recorded densities 1-3 pairs/ha; 100-150 pairs in Croatia, 300-800 in Albania, 3000-5000 in Greece, 1000-5000 in Romania, 3000-5000 in Moldova; up to 10,000,000 pairs in Russia, densities 1-2 pairs/ha. Breeds on major Mediterranean islands, i.e. Sardinia, Sicily (fairly common), Crete and Cyprus (common, 10,000-25,000 pairs, post-breeding flocks of up to c. 1000). In N Africa, common in Morocco (especially N of Marrakech and in E), widespread in Tell and Hauts Plateaux of Algeria (flocks of up to several thousands in Oran region), and common in N Tunisia (locally in large numbers); in Libya scarce on Tripoli coast (breeding not proved) and common breeder in NE coastal plains (Barce cornlands). Estimated 100,000-1,000,000 pairs in Turkey (common on plains and fields of W & C, but scarce or absent at higher altitudes in E). Reported as very rare in Armenia, common in Azerbaijan, and scarce and local in Lebanon (Beqaa Valley); c. 4000-6000 pairs in Israel in 1980s. In former USSR said to be occasionally very common, and in some places abundant (up to 2 pairs/ha). Recent range contractions and declines in many countries, especially France, where perhaps over 400 pairs in 1980 but fewer than 50 in 1997 (was common in 19th century in all Mediterranean climate regions, also scarce breeder in Corsica, but strong decline since early 20th century and now absent from most areas); in Italy has disappeared from NE coastal belt and Tuscany region of Italy, and reductions noted also in Spain, Greece and Israel; declines recorded in Ukraine and also in Kazakhstan (between R Volga and R Ural), but said to have spread N during 1970s in intervening part of S Russia (Voronezh region). Negative trends usually associated with agricultural intensification and resultant land-use changes (loss of fallows, change from cereal crops to vineyards or olive groves, new irrigations, etc.), also with decline in extensive sheep-rearing, and with afforestation schemes. Species is reported as causing some damage in cereal cultivations in Iraq in winter.

64. Bimaculated Lark

Melanocorypha bimaculata

French: Alouette monticole **German**: Bergkalanderlerche **Spanish**: Calandria Bimaculada
Other common names: Eastern Calandra Lark

Taxonomy. *Alauda bimaculata* Ménétriés, 1832, mountains near Talysh (= Talyshskiye Goro), on Azerbaijan-Iran border.
Geographical variation slight; rufous-tinged birds from Asia Minor described as race *rufescens* and paler ones from E Iran and Afghanistan as *torquata*, but considered insufficiently distinct to merit subspecific separation. Monotypic.
Distribution. Breeds from WC Turkey E to Armenia, S Azerbaijan and W & S Iran and, E of Caspian Sea, to SE Kazakhstan, Kyrgyzstan, NE Iran and N Afghanistan; also isolated populations in Lebanon, N Israel, S Syria and N Iraq. Winters in NE Africa, S Middle East and N Arabia E to NW India.

Descriptive notes. 17-18 cm; 47-62 g. Large, fairly robust lark with deep-based heavy bill, rather long wings, short tail. Has prominent whitish supercilium, distinct dark loral stripe, rufous-tinged ear-coverts; above, buffy grey-brown or more rufescent grey-brown, heavily streaked blackish; wings and tail dark grey-brown, upperwing-coverts and tertials with pale buffish tips and edges, rectrices with broad white tips (except central pair); whitish or pale buffish below, breast side tinged more buffish, with fine dark streaks, prominent blackish patch on side of lower neck/upper breast (patches often meeting thinly in centre); underwing brown-grey; bill yellowish or pinkish, dark culmen and tip of lower mandible; legs pinkish to yellowish. Distinguished from *M. calandra* by more contrasting head pattern, shorter tail and, in flight, shorter and more triangular wings (characteristic silhouette, somewhat like that of a *Sturnus* starling), less contrastingly dark primaries above, no white trailing edge of wing, more prominent white tip of tail but no white outer rectrices, paler underwings. Sexes similar, female on average smaller. Juvenile has distinct whitish fringes and dark submarginal bands above (scaly impression), breast patches lacking or less obvious. Voice. Song, in flight, less often from ground or low perch, a protracted fast twittering, like that of *M. calandra* but simpler, more monotonous, harsher and more grating, and includes less mimicry. Most calls harsh, rolling and drawn out, can be very like those of *M. calandra* but frequently deeper and more throaty.
Habitat. Open habitats; generally stonier and less grassy terrain and, when breeding, in more mountainous or hilly country (to c. 2700 m) than areas preferred by *M. calandra*, but both species sometimes breed together in flat, dry grassy areas in plains.
Food and Feeding. Invertebrates and seeds. Invertebrates include adults and non-adults (eggs, larvae, pupae) of orthopterans, termites (Isoptera), bugs (Hemiptera), lepidopterans, flies (Diptera), hymenopterans, beetles (Coleoptera), arachnids; seeds include those of e.g. *Sorghum*, *Amaranthus*,

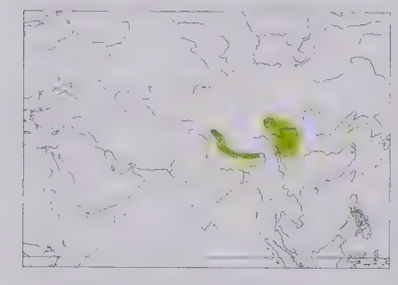
Leguminosae, *Hypericum*, *Galium*, *Heliotropium*, Gramineae. Adults in breeding season apparently feed mainly on invertebrates, and these also form main or sole diet of nestlings. Forages on ground, singly or in flocks.

Breeding. Season late Mar/early Apr to mid-Aug; sometimes two broods. Male song flight in irregular "circles" at low height, with rather slow, somewhat jerky wingbeats and closed tail, or hanging rather still, or drifting about high up and with usually rather quick, continuous wingbeats and spread tail. Nest, built by female alone, a loose cup of grass and rootlets, with thinner material internally than externally (outer walls may also contain pieces of paper, rags and dung), in depression on ground, usually sheltered by tussock or small bush. Clutch 3-6 eggs, generally 4 or 5; incubation by female only, period repeorted variously as 12-13 or 14-15 days; young leave nest at 9-12 days, but not capable of flying until c. 15-16 days, fed by both parents for up to 30 days.

Movements. Migratory; possible resident in parts of extreme S of range. Winters mainly in CE Sudan, N & NE Ethiopia and Eritrea, also through N Saudi Arabia and in S Iran, and S Turkmenistan, Uzbekistan and W Tadjikistan S through W & S Afghanistan and E Iran to S Pakistan and NW India; scarce or irregular winterer in Israel, Jordan, Arabian Gulf coasts, and Oman. Spring migration in Feb to late Apr; autumn migration in Sept-Nov, chiefly Oct to early Nov. Rare but regular on passage in most Middle East countries and in Cyprus. Vagrants recorded in several European countries, also in Namibia and Japan.

Status and Conservation. Not globally threatened. Locally common; scarce to rare in parts of range. Widespread and locally common to very common in Armenia; in Azerbaijan, uncommon to common generally but very common in N (Nakhichevan region). Bred in Kuwait in 1978. Estimated 5000-50,000 breeding pairs in Turkey; c. 40 pairs in Israel, at two sites. No obvious threats but, as with most Asian larks, land-use changes could potentially have an adverse impact.

Bibliography. Adamian (1963), Adamian & Klem (1999), Ali & Ripley (1987), Alström *et al.* (2004), Andersson & Larsson (1985), Baglieri & Iapichino (1979), Beaman & Madge (1998), van den Berg (1987), Bergmann & Helb (1982), Beshir (1978), Brazil (1991), Brooke (1988), Bub & Herroelen (1981), Castell (1996b), Cramp (1988), Dementiev *et al.* (1970), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Étchécopar & Hüe (1964, 1983b), Flumm (1977), Gavrilov (1999), Glutz von Blotzheim & Bauer (1985), Grimmett *et al.* (1998), Harris *et al.* (1996), Heath *et al.* (2000), van Heezik & Seddon (1999), Holtom *et al.* (1988), Hüe & Étchécopar (1970), Jennings (1995), Jones (1965), Jonsson (1992), Keith *et al.* (1992), Korelov (1970), Lewington *et al.* (1991), Lindroos & Tenovuo (2000a), Mackworth-Praed & Grant (1960), Mild (1990), Pätzold (1994, 2003), Porter *et al.* (1996), Ripley (1982), Roberts (1992), Roselaar (1995), Shirihai (1996), Simms (1992), Snow & Perrins (1998), Stepanyan (1990), Svensson (1992), Ullman (1990), Vaurie (1951a, 1959), Whitehouse (1978).



65. Tibetan Lark

Melanocorypha maxima

French: Alouette du Tibet **German**: Sumpflerche **Spanish**: Calandria Tibetana
Other common names: Asiatic/Long-billed (Calandra) Lark

Taxonomy. *Melanocorypha maxima* Blyth, 1867, borders of Sikkim.
Geographical variation relatively insignificant. Several races described, including *kashmirica* (E Kashmir), *flavescens* (W Nan Shan, Gansu), *holdereri* (Gansu, later interpreted as SW Tibetan Plateau NE to E Qinghai and Gansu) and *subgrisea* (NE Qinghai), but considered insufficiently distinct to merit recognition. Monotypic.

Distribution. Tibetan Plateau from NW India E to C China (NE Qinghai, Gansu, extreme W Inner Mongolia & NW Sichuan).

Descriptive notes. c. 21-22 cm; up to 75 g. Distinctive; the largest and most bulky Eurasian lark, with rather long, comparatively slender, slightly decurved bill, broad longish wings, fairly short tail. Has poorly marked head, heavily dark-streaked brownish upperparts, dark grey-brown upperwing-coverts and tertials with pale tips and edges; remiges and rectrices blackish-brown, secondaries and inner primaries with broad white tips (white trailing edge in flight), most rectrices with whitish tips (width increasing outwards), outermost pair extensively white; mainly whitish below, blackish patch on side of lower neck/upper breast, pale underwing-coverts; iris dark brown; bill pale pinkish basally, turning greyer and darker towards tip; legs dark grey with pinkish tinge. Sexes alike in plumage, female smaller than male. Juvenile has distinct pale buffish or whitish fringes and dark subterminal bands above, including wing-coverts and tertials, lacks dark breast-side patch but shows indistinct dark spots on side of breast. Voice. Song, from ground or in flight, rich and varied, rather slow-flowing, often includes mimicry of other birds and characteristic call-like grating notes, may be continuous for long periods or split into shorter strophes. Calls rather low-pitched and grating.

Habitat. Usually found in grassy, somewhat wet areas, such as marshlands by lakes and rivers. Generally between 4300 m and 4600 m in NW India; at or above 3200 m in NE part of range.

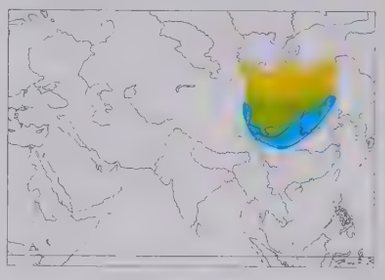
Food and Feeding. Diet poorly known: seeds, tender leaves, berries and invertebrates taken. Forages on ground.

Breeding. Little studied. Season Apr-Jul/early Aug; two broods. Male song flight at low or high altitude, with rather slow wingbeats, often gliding on V-held wings low over ground before landing. Nest built by female, a cup of grass on ground. Clutch 2 or 3 eggs, rarely 4; incubation and fledging periods not known; young fed by both parents.

Movements. Sedentary or dispersive.

Status and Conservation. Not globally threatened. Locally common. A relatively poorly known species; no population estimates.

Bibliography. Ali & Ripley (1987), Alström *et al.* (2004), Cheng Tsohsin (1987), Deng Heli & Zhang Xiaoai (1988), Deng Heli *et al.* (1991b), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Étchécopar & Hüe (1983b), Grimmett *et al.* (1998), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Nadler (1991), Pätzold (1994, 2003), Rasmussen & Anderton (2004), Ripley (1982), Vaurie (1951a, 1959, 1972), Wang Xiangting (1991), Zhao Zhengjie (2001), Zheng Baolai (1985).



66. Mongolian Lark

Melanocorypha mongolica

French: Alouette de Mongolie **German**: Mongolenlerche **Spanish**: Calandria de Mongolia
Other common names: Mongolian Sand Lark, Mongolian Skylark

Taxonomy. *Alauda mongolica* Pallas, 1776, northern Mongolia.
Monotypic.

Distribution. Breeds Mongolia and neighbouring parts of S Russia and NE China.

Descriptive notes. c. 19 cm. Rather large, quite large-billed, fairly long-winged lark with distinctive pattern. Has long whitish supercilia joining across nape, latter bordered below by rufous band, unstreaked rufous crown with pale centre, grey-brown upperparts streaked blackish; lesser and median wing-coverts rufous, greater coverts and tertials dark grey-brown with pale tips and edges; remiges blackish, distal ends of secondaries and inner primaries white (very broad white trailing edge in flight), blackish or dark grey-brown primary coverts; tail blackish, central feather pair browner, outermost pair white; white below, large black patch on side of lower neck/upper breast, white underwing-coverts; iris dark brown; bill pale pinkish or yellowish, tip grey, culmen often grey; legs pale pinkish. Distinguished from *M. leucoptera* mainly by different head pattern, black patch on neck/breast side, dark grey-brown primary coverts, even more white on rear wing. Sexes similar in plumage, female on average smaller. Juvenile lacks rufous colours and prominent black neck patch (but has dark spots on breast, mainly on sides), has distinct pale buffish or whitish fringes and dark submarginal bands above. Voice. Song, from ground or low perch or in flight, a sustained twittering with interspersed dry notes, reminiscent of that of congeners, especially *M. bimaculata*. Various harsh, rolling and high-pitched calls.

Habitat. Favours rather dry grassland, preferentially with patches of denser, taller grass, but also in damper areas with lush grass. Sometimes also in more rocky uplands.

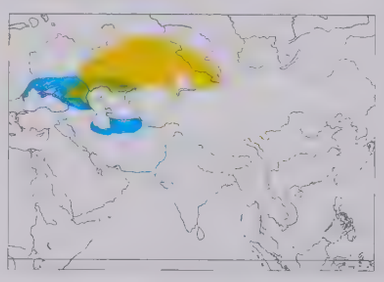
Food and Feeding. Little information. Diet seeds and invertebrates.

Breeding. Little studied. Season mainly Apr-Aug; two broods. Male song flight with rather slow wingbeats, sometimes quivering on bowed wings. Nest not fully documented, said to be similar to that of congeners. Clutch 3-5 eggs; incubation period 15 days; no information on nestling period.

Movements. Sedentary or short-distance migrant; N parts of breeding range mainly or completely vacated in winter. Spring migration Mar to early May, mainly in second half of Apr; autumn migration late Aug to Oct or early Nov. In severe winters, may reach well S of breeding range.

Status and Conservation. Not globally threatened. Uncommon to locally common. Rather poorly known species; no population estimates.

Bibliography. Alström *et al.* (2004), Belik (1990), Cheng Tsohsin (1987), Dementiev *et al.* (1970), Étchécopar & Hüe (1983b), Hsu Weishu (1988), Liu (1998), MacKinnon & Phillipps (2000), Madge (1988), Mauersberger (1982), Pätzold (1994, 2003), Rozendaal & Kortekaas (1980), Stepanyan (1990), Vaurie (1959, 1972), Wang Xiangting (1991), Zhao Zhengjie (2001), Zheng Baolai (1985), Zheng Guangmei & Zhang Cizu (2002).



67. White-winged Lark

Melanocorypha leucoptera

French: Alouette leucoptère **German**: Weißflügellerche **Spanish**: Calandria Aliblanca

Taxonomy. *Alauda leucoptera* Pallas, 1811, Baraba Steppes, south-central Russia.
Monotypic.

Distribution. Breeds SW Russia (S to NW Caspian Sea) E to L Balkhash. Winters S to Black Sea region and N Iran.

Descriptive notes. c. 18 cm; male 40-52 g, female 36-48 g. Rather well-proportioned lark with moderately large bill, long wings, distinctive wing pattern. Male has rufous forehead, crown and rear ear-coverts with little or no dark streaking, whitish supercilium and anterior ear-coverts; in fresh plumage (autumn) head less rufous and more streaked; upperparts grey-brown with moderately prominent dark streaks, lesser wing-coverts and primary coverts rufous, median and greater coverts and tertials dark grey-brown (often some rufous on at least median coverts) with paler tips and edges; remiges blackish, secondaries and inner primaries with extensive white distally (very broad white trailing edge in flight); tail blackish, central feather pair browner, outermost pair white; whitish below, breast side rufous-tinged and very finely streaked dark (less rufous and more streaked in fresh plumage); white underwing-coverts; iris dark; bill pale grey to pinkish, culmen and tip of lower mandible dark grey; legs dark grey or pale pinkish. Distinguished from *M. mongolica* mainly by different head pattern, no black patch on neck/breast side. Female has little or no rufous on head and breast, breast finely streaked. Juvenile lacks rufous, has distinct whitish fringes and dark subterminal bands above. Voice. Song, from ground or low perch or in flight, a protracted mix of twittering and trills with interspersed harsher notes and mimicry, reminiscent of that of e.g. *M. calandra* but higher-pitched and less coarse. Calls with various short, harsh or high-pitched, often multisyllabic, notes.

Habitat. Breeds mainly on flat or slightly undulating, dry grass steppe (e.g. *Stipa* and *Festuca*) or wormwood (*Artemisia*) steppe, less often in cultivated fields. In non-breeding season found in wider range of grassy habitats, including stubble fields.

Food and Feeding. Invertebrates and seeds. In summer, apparently mainly insects; in one study, beetles (Coleoptera) formed up to 50% of diet, orthopterans 32% and lepidopterans (including caterpillars) 16%, with Hymenoptera, bugs (Hemiptera) and spiders (Araneae) infrequent. Seeds of e.g. Chenopodiaceae eaten in summer, while in non-breeding season those of *Setaria viridis* and *Carex stenophylla* as well as cereal shoots have been noted in diet; seeds apparently main food in winter. Forages on ground, in pairs or in small groups, but outside breeding season sometimes in large flocks.
